THIS monograph summarises recent work upon the pathology and treatment of a very common affection. The scope and value of radium, X rays, or diathermy are clearly set out, while older methods are clearly described Particularly interesting are the chapters upon prostatism without enlargement and per urethral methods of operating The author's own experience shows just what can be effected by these methods and when they are indicated The general account of prostatectomy is good Mr Kenneth Walker does not seem to practise perineal prostatectomy, but he sums up very fairly (p 139) the advantages and drawbacks of each method It is a little difficult for the reader to find advice as to what preliminary treatment he should give and what examinations should be made in cases where operation is contemplated—such examinations, for instance, as the estimation of blood pressure and cardiac efficiency, and determination of the hæmoglobin content of the blood, all of which are potent factors influencing the outcome of the operation Most of this information is to be found in the book, but it is not collected in one place conveniently for reference This is the sole criticism we have to make of an otherwise excellent account of the enlarged prostate

TUBERCULOUS LESIONS OF THE EYE

Die Tuberkulösen Erkrankungen des Auges By Dr. RUDOLF BERGMEISTER, Privatdozent for Ophthalmology in the University of Vienna Berlin. S Karger 1927 Pp 143 M 6 60

THE main purpose of this book appears to be to put the specific treatment of tuberculous diseases of the eye on a sound theoretical basis and to advocate its more general employment The critic may object that too exclusive attention is paid to this method of treatment and especially that the most recent method recommended for these cases—ultra-violet radiation—receives but scanty notice Moreover, it seems to be taken for granted that so-called scrofulous or phlyctenular diseases are actually the result of a tuberculous toxin in subjects rendered supersensitive by a previous and, perhaps, unnoticed attack of tubercle Though this theory may be found to be true of some cases, the general consensus of opinion is that it does not apply to the majority The author quotes a large number of German-writing authorities; the absence of an index detracts from the convenience of his book and the entire absence of illustrations makes it hard reading for the British reader It contains, however, some interesting and important matter Original observations are few but include the occurrence of a corneal necrosis in a case of lupus As an unusual example of reaction to tuberculin cases he has noted the wandering of pigment from the periphery towards the centre in foci of choroiditis The shrinking of the sclera in cases of scleritis treated with old tuberculin is given as another example of focal reaction to be avoided The form in which the author recommends the treatment is the bacillus emulsion in small doses systematically increased during a prolonged period

THE SEPTIC PROBLEM.

A Solution of the Septic Problem and a New Theory of Immunity By D. MONTGOMERIE PATON, L R C P., L R C S Edin. London: Baillière. Tindall and Cox 1927. Pp 204 7*s* 6*d*

THE subject matter behind this ambitious title is neither logical exact. nor plausible As far as can be made out the author believes that antibodies are of two sorts: the one specific and only acting when free in the lymphatic system, and the other non-specific. acting when present in the blood. He attributes the production of the former, which in his view may be represented by diphtheria antitoxin, to the lymph glands and proceeding from this hypothesis states that on this account it is only capable of exerting its specific influence in the lymphatic system, which explains its uselessness when given orally. as a corollary he believes that other, non-specific, antibodies can be absorbed from the digestive tract and exert their effect in the blood A portion of the book is devoted to such theoretical considerations, and abounds with statements of the type that ‘ The endocrine defence lies in an increased potency and in a hormone balance specific for the antigen present,” and “ diphtheria toxin. having a proteolytic action like the streptococcus evokes a hormone and antitryptic balance which is capable of a definitely increased tissue resistance to all three organisms ” If any definite idea lies behind this phraseology it is effectively obscured The outcome of the book is that great therapeutic virtues are claimed for diphtheria antitoxin administered by the mouth and subcutaneously. in a large range of disorders from varicose ulcers to lobar pneumonia

SAMUEL HAHNEMANN. HIS LIFE AND WORK.

By RICHARD HAEHL. M D. Translated from the German by Mrs MARIE L. WHEELER and Mr. W. H. R. GRUNDY. B.A London. Homœopathic Publishing Co 1926 Vol I, pp 443; Vol. II, pp 514 £3 3*s*.

THOSE who can spare the time and the labour to read through the two volumes containing nearly 1000 pages of closely set type will be more astonished than anything else at the remarkable mixture of common sense and credulity. of sound medical practice and of quackery. and of scientific insight and unscientific absurdities which characterise Hahnemann's career. He was one of the first to recommend and to put in practice a sensible and kindly treatment of lunatics; he was a pioneer in public health, in the proper way in which to bring up children and in sanitation He fought against excessive blood-letting and also against the absurd polypharmacy in vogue at the end of the eighteenth century and for some years later And yet he could write such a childish tirade against the use of coffee as we find upon page 60 of Vol. II and evolve all the Hahnemannian theories and practices of psora, and provings and decillion dilutions Dr. Haehl has collected with fearful care every conceivable scrap of information about his hero There are innumerable letters from and to Hahnemann, *most* of them dealing with trivialities such as that Hahnemann used a steel pen Lists of objects belonging to Hahnemann and his relations are all solemnly put down—e g, “Two red lacquered spittoons; five iron dog chains; four dogs' drinking troughs· one mouth harmonium with case” The book would have made better reading had its bulk been curtailed

---

MENTALITY OF SUBTHYROIDIC CHILDREN

Geistige Entwicklung Hypothyroidischer Kinder bei Spezifischer Behandlung. By Dr. W. KORNFELD. Berlin. S. Karger. 1926 Pp 38. M 2 70.

THIS monograph consists of an account of the mental progress of 15 subthyroidic children. mostly cretins while undergoing specific treatment, with an extremely judicial and thoughtful elaboration of the results disclosed. The perversity of parents provided the author with opportunities of observing the effect of temporary cessation of treatment, which adds to the value of the records. Detailed results of mental testing are tabulated, and Dr. Kornfeld points out that the mental retardation of cretins has some characteristics which separate it from that of primary aments, the functions of attention and initiative being impaired beyond all others. He stresses the fact that organotherapy does not in itself produce true mental improvement, comparable to the physical improvement which takes place; it renders the brain susceptible to improvement, but this can only be achieved by active educative measures The defect of the customary method of dealing with these cases lies in its failure to fulfil these conditions. Patients who had made rapid progress in a special school. and who had been rendered fit for unskilled labour, at the age of 14 or so were passed on to mechanical tasks and no longer actively educated; the result of this was an improvement far below that which can be attained, or sometimes actual deterioration The subthyroid adolescent requires a definitely longer period of education than the normal one, and unless this is conceded to him the money spent on his welfare by the State does not produce an economic return.

The accounts of the individual cases bring out numerous points of interest. and Dr Kornfeld may be congratulated on making a really valuable contribution to the study of amentia

---

THE BLACK DEATH.

A Chronicle of the Plague. Compiled by JOHANNES NOHL from Contemporary Sources Translated by C. H. CLARK. Ph D London. George Allen and Unwin 1926 Pp 284 12*s* 6*d*.

THE Plague of London has always fascinated the most superficial of students of history, standing out with the signing of the Magna Charta and the Gunpowder Plot and the beheading of Charles I. as an incident remembered not only by every school-boy but also by his elders. This is not to say that such high lights are always vivid and discrete A child, whose mind was being racked by the inquisition of a general knowledge paper when asked what he knew of “Habeas Corpus” replied “Habeas Corpus was what you said to the driver of the dead cart in the Great Plague. It means, ‘You may take the body.’ ”

The tradition of the widespread epidemic of 1348 has also been retained for 500 years and it is curious that there should still be room for researches as to its immediate and remote effects. This book is mainly concerned with the cultural and social aftermath of the scourge The narrative is drawn almost entirely from contemporary sources, extracts being given verbatim and hence has a pictorial value which no mere history can possess On the whole it is a most valuable study of the period. though here and there extraordinary statements show the danger of not verifying references. For instance, on p 177 is a story about how a man was taken by the Devil to a house in Milan and asked to sell his soul to the fiend, we are told that “ the description of the house shows a remarkable similarity with Homer's description of Circe's cave The terrible and the majestic, the charming and the horrible were standing cheek by jowl.” Now Homer distinctly says that Circe lived in a house in a clearing. and that the house was built of polished *stone*: neither was there anything horrible about the interior Again. on p 235 in talking about the Black Death and the Flagellants the author says “ Their cult was a cult of repentance and as such was intended as a direct imitation of Christ, such as a few centuries later was taught by Thomas à Kempis in his splendid book”· from 1348 to 1420 the generally received date of the De Imitatione, is not even one century. We also doubt whether the statement on p 208 that the erotic carvings in some of the French churches are due to the general laxity of morals prevailing during the plague in the fourteenth century is correct, for as a matter of fact some of the carvings in question are as old as the eleventh century. Other faults of detail are a certain indefiniteness about dates and an omission of full references to the source of the quotations given; otherwise the book deserves unqualified praise A quaint story finds a place of a quack who sold amulets as a preventive On no account was the amulet to be opened and read before 14 days had elapsed. They were bought in vast quantities and the quack, having raked in much money, departed At the end of the prescribed period everyone opened his amulet to read the charm, and found nothing but a rude couplet in Italian The copious bibliography appended to this interesting work will be of great value to those who wish to pursue the subject further, for it contains names, for the most part, unfamiliar

DEMENTIA RACHITICA

By Dr KURT HULDSCHINSKY Berlin. S Karger 1926 Pp 60 M 2 70

THIS monograph describes an investigation into the so-called cerebral component of rickets The first part consists of an account of some of the nervous manifestations of this disease, with an attempt to classify them as "psychic" or "somatic," which leads to some curious results Tetany is admitted to be somatic, but sweating and spasmus mutans are both classed as psychic, no mention being made of the association of the latter with nystagmus and other objective factors The results of a series of intelligence tests are given; these do little to justify the title of the work, as they yield no evidence of any mental defect, except a moderate degree of retardation, which occurs *as a result* of rickets The psychological explanation of "rachitophrenia," by analogy with schizophrenia at a later age, appears far-fetched, and will probably fail to satisfy the majority of clinical observers

THE BEHAVIOUR OF ANIMALS

The Natural History of Ants By RENÉ ANTOINE FERCHAULT DE RÉAUMUR Translated and annotated by W. M WHEELER, Professor of Entomology in Harvard University. New York A. A Knopf 1926 With 2 portraits and 2 facsimiles. Pp 280 25*s*

RÉAUMUR was born in 1683 and after a career of amazing industry and versatility died in 1757 He discovered how to make steel, invented a thermometric scale, incubated eggs, artificially studied digestion in vitro, wrote on the effective sealing of museum jars (the paper is translated in the Philosophical Transactions of the Royal Society (1748) of which he was a foreign member), and in one way or another illuminated an extraordinary variety of other subjects But he is perhaps best known for his great "Mémoires pour servir a l'Histoire des Insectes" of which the six volumes published during his lifetime are enough to place him in the first rank of those who have worked at the life-history and habits of insects He left materials for further volumes in a more or less coordinate condition, and his treatise on ants has been retrieved from the archives of the Institute by the pious care of Prof Wheeler We are given here the original text, a translation, many illuminating and scholarly notes, and, as a preface to the whole, a most interesting account of Réaumur's life and the position he occupied in relation to his contemporaries and to the progress of knowledge before and since To anyone with a feeling for natural history the book will be a delight It is so beautifully produced that there is no harm in noting that on p 36, line 13, a "no" seems to be astray and that the "Annotations" should have had back references to their germane text.

A HANDBOOK FOR SENIOR NURSES AND MIDWIVES

By J K WATSON, M D Edin London Humphrey Milford, Oxford University Press 1926 Pp 554 12*s* 6*d*

THE modern nurse is expected by her patients to have some knowledge of such subjects as encephalitis lethargica, insulin, endocrine therapy, and twilight sleep Unless she is prepared to read medical periodicals it is difficult for her to keep abreast of medical progress, and Dr Watson, whose previous handbooks for nurses and midwives showed him to be a shrewd writer in this sphere, has therefore brought out a supplementary volume intended principally for the senior nurse, sister, and experienced midwife The works from which much of the material in this book has been obtained is a guarantee that it is authoritative and up to date The book is divided into four parts medical, surgical, pædiatric, obstetrical and gynæcological, and in each section various important subjects are treated in a manner too detailed for the needs of the young probationer, but admirably suited to those of the sister The author begins with a chapter on preventive medicine, followed by one on the problem of cancer and another on the use of alcohol, subjects very much before the public on which the intelligent nurse is supposed to have some opinion On controversial matters the author gives both sides fairly; his account of the arguments for and against twilight sleep is particularly good, as is also the description of the method of conducting labour when it is used The book is well printed, illustrated, and indexed

New Inventions.

A LIPIODOL TROCAR AND CANNULA

THE only part of a lipiodol injection into the trachea by the cricothyroid membrane route which presents any difficulty is the insertion of the needle through this membrane If the needle is sharply pointed it is dangerous because it may lacerate the posterior wall of the trachea when the patient swallows or coughs, if it is bluntly bevelled it is difficult to push through the membrane, and painful and undesirable pressure may be needed A trocar and cannula has the advantage that it can be sharp when inserted and blunt when in position I therefore asked Messrs Allen and Hanbury to make the instrument shown in the illustrations The cannula is 2 cm long and the bore is 1 mm in diameter It is made to fit any Record syringe, and does so perfectly and easily, requiring no pressure to keep it in position, and there is no leakage of oil The shoulder of the trocar must adequately cover the end of the cannula When tested by pushing the instrument through linen or rubber there should not be the slightest catching of the cannula So often trocars and cannulas are sent out with glaring defects in this respect, and it is unpardonable. I have now used the instrument for several months and find it perfectly satisfactory It is easy to handle, and in spite of the small bore the oil flows perfectly if warmed to body heat

'Byno' Hypophosphites

Trade Mark

An efficient Digestive, Tonic and Restorative

Invaluable in retarded convalescence and asthenic conditions generally.

In 'Byno' Hypophosphites are combined the tonic qualities of the Nux Vomica and Cinchona alkaloids, the restorative value of the mineral hypophosphites, and the nutritive and digestive powers of 'Bynin' Liquid Malt, which is the basis of the preparation

'Byno' Hypophosphites has for long been prescribed with great success in convalescence after acute infections and following surgical operations, in nervous and mental conditions due to overstrain or exhaustion; as an adjunct in the treatment of tuberculosis, in asthenia of the aged, and in a diversity of conditions where a general tonic and digestive is indicated.

COMPOSITION

Calcium Hypophosphite	2 gr	Iron . .	¼ gr	Nux Vomica Alkaloids	
Potassium	2 „	Manganese	¼ „	(equal to Strychnine)	$\frac{1}{40}$ gr
Sodium . . .	2 „	Cinchona Alkaloids	1½ „	'Bynin' Liquid Malt .	1 oz

10 oz bottles 3/6; 20 oz 6/6, 40 oz 12/-

Further particulars and free sample will be sent on request

THE LANCET.

LONDON: SATURDAY, FEBRUARY 26, 1927.

DISTEMPER AND INFLUENZA

The administration of a national fund set aside for the initiation and development of medical research is liable to criticism from every taxpayer who is excited by the recollection of an undiagnosed pain or annoyed by the inconvenience of a recurrent infection. His chief plaint, sometimes, alas, supported by his harassed medical adviser, is that researches into abstruse bacteriological or biochemical problems are subsidised while the nature of common affections such as influenza remains unknown. In the introduction to their Annual Report for 1925–26, which we summarise on another page, the Medical Research Council patiently explain once more the many reasons why it is futile, even were it possible, to attempt to direct research into purely utilitarian channels. It is impossible because the elusive beam of light that some men are able to shed on problems that interest them is likely to be extinguished if they are pressed to turn it on dark places. It is futile because not even the worker himself can guess beforehand whether a given piece of knowledge is destined to have a direct bearing on medical practice. For example, the structure and distribution of the sterols—a group of complex solid alcohols of which cholesterol has the widest distribution in the animal body—has been for many years the subject of intensive research by organic chemists, notably A. Windaus in Göttingen, I. M. Heilbron in Liverpool, and H. J. Channon and J. A. Gardner in London. Quite recently[1] it has been shown by workers in the National Institute for Medical Research that the anti-rachitic vitamin D is actually formed when certain sterols are exposed to ultra-violet light, and already in our columns last week it was announced that a commercial preparation of ergosterol, believed to be at least 20 times more potent than cod-liver oil in the prevention and treatment of rickets, is available for trial by medical men.

In contrast with this sudden practical application of what seemed to be academic investigations is the way in which progress in the study of common diseases may be hampered by failure to discover an appropriate technique. If the critics of the Medical Research Council took the trouble to study the serial story told in successive annual reports they would see that many beginnings have been made to study apparently simple problems. Each time these have been found to depend on so many unknown factors that they cannot be approached with any hope of success until more is known of the complex processes of metabolism or of infection and immunity. For example, it is now nearly four years since the Field Distemper Fund was inaugurated to facilitate the study of the cause, prevention, and cure of canine distemper. High hopes were entertained of speedy results, for the reasons which prevent the direct study of comparable human diseases—the impossibility of experimental infection on a large scale and of controlled tests of the potency of remedies—do not apply. Moreover, since distemper occurs spontaneously in dogs, its experimental reproduction can be effected by direct contagion as well as by artificial means, and comparison of the course of the disorders produced need leave no doubt as to their identity. Yet, in spite of these facilities, concentrated research has done little as yet but reveal the magnitude of the problem. Carré's view that distemper is caused by a filter passing virus and not by micro-organisms visible by ordinary methods has been confirmed; but progress has been seriously handicapped by the failure in spite of persistent trials "made with every effort that experience and ingenuity can suggest" to propagate the distemper virus outside the animal body. Ferrets, which are highly susceptible to canine distemper, can be immunised to the infection by means of inoculation with a virus killed or inactivated by formalin, but this weakened virus gives only temporary immunity to dogs, though it appears to modify the course of an attack of the disease subsequently induced by fresh virus. The fact that susceptibility of individual dogs to distemper is highly variable adds to the difficulty of testing the effect of preventive inoculations. It is clear that before any method can be devised to give complete and lasting immunity to dogs, a virus of known and constant potency must be available and dosage must be accurately standardised. Until the virus can be cultivated outside the animal body the inoculation can only be crude and its content of active material uncertain. The Medical Research Council hold out little hope that a practical method of protecting dogs, suitable for general use, will be obtained until the nature of the virus, the right methods for its cultivation, and its laws of behaviour have been ascertained. This pronouncement will be appreciated and endorsed by all who understand the problems at issue. It follows that it is foolish to clamour for official guidance as to the prevention of influenza, the ætiology of which is even more obscure, for it is not yet established whether it is caused by a visible or an ultra-microscopic organism. The Council point out the analogy between distemper in dogs and influenza in man, and suggest that the right weapons for attack upon influenza are perhaps only to be forged in the easier experimental study of the animal maladies nearest akin to it.

The report, as a whole, is a fascinating record of work done at home and abroad, by chemists in laboratories, and practitioners at the bedside. It includes accounts of organised researches subsidised by the Council over a term of years, and notes of temporary facilities or assistance granted in order to bring certain workers together for a short time or to prevent the waste of material during a transition period. The report concludes with a list of 700 men and women named therein, the large majority of whom have received from the Council personal grants or paid assistance. There is a corresponding list of 80 institutions where work is being carried on wholly or partly under its auspices. Nearly all those selected for appointment year by year to the chairs under the medical faculties of our universities are men who have at one time held research grants from the Council, if indeed they do not relinquish these only on obtaining a full-time academic post. It is noteworthy that two of the candidates recently recommended for the signal honour of Fellowship of the Royal Society—Dr. P. P. Laidlaw and Mr. O. Rosenheim—are attached to the National Institute for Medical Research at Hampstead. The Council refer to a present shortage of young men of first rank available for research—a shortage which they attribute to the direct and indirect effects of the war. They are obviously keen to detect every sign of ability and to let no flicker of bright promise die out for lack of protection Nobody can press a switch and turn a flood of light into the dark caves of medical ignorance The function of the Medical Research Council, which they fulfil with fine discrimination tempered with most kindly tolerance, is to see that no one who has flint lacks steel, and that where even a tiny spark is produced tinder shall not be wanting

◆

THE TESTS FOR DRUNKENNESS

In October, 1925, a Committee was appointed by the Council of the British Medical Association to consider and report on the present tests for drunkenness, and to make recommendations as to their improvement The Committee included the President of the Association, the chairman of its Council and of its Representative Body, and its treasurer, several divisional surgeons of the Metropolitan Police Force, two Metropolitan magistrates, and certain well-known clinicians and scientists like Dr **Farquhar Buzzard**, Mr J T J **Morrison**, Mr. E B **Turner**, and Sir **William Willcox**, the chairman being Major-General Sir **William Macpherson**, A M S The institution of the inquiry was immediately due to the notoriety given by the press to certain cases where persons had been convicted of drunkenness when in charge of motor cars There were here two pronounced waves of feeling first, that the public must be protected from the gross risks brought about through the reckless driving of motor vehicles, and, second, that the acuteness of this apprehension had led to the sentencing, as drunken, persons whose condition had not been properly tested—in short, there was a view that, in order to ensure the non-escape of the guilty, the innocent had been more than occasionally penalised

The Committee show by the report that they have considered closely the procedure usually adopted in police-courts for dealing with cases of alleged drunkenness, for they print in an appendix a resumé of what happens in London and in most of the larger towns, and for purposes of comparison describe also the procedure in the Navy and Army, and that in certain foreign countries such as Denmark, France, and the United States of America A further appendix consists of a memorandum on the particular offences where drunkenness plays a part, a list being thus presented of the circumstances in respect of which a doctor may be asked to express an opinion as to the existence of drunkenness in a particular individual In the body of the report the Committee suggest that the word "drunk" should always be taken to mean that the person concerned was "so much under the influence of alcohol as to have lost control of his faculties to such an extent as to render him unable to execute safely the occupation on which he was engaged at the material time" Medical practitioners will agree that the adoption of this as a definition would clear away some of the difficulties in certain classes of case The usual deliberations for establishing the fact that an individual is under the influence of alcohol having been reviewed, the general conclusion is come to that no single test taken by itself justifies a medical practitioner in deciding that the amount of alcohol consumed had caused a person to lose control of his faculties "to such an extent as to render him unable to execute safely the occupation on which he was engaged at the material time" A correct verdict, it is held, can only be arrived at by the consideration of a combination of several tests and observations such as "general demeanour, state of the clothing, appearance of conjunctiva, state of the tongue, smell of the breath, and character of the speech" These manifestations are to be noted in connexion with the manner of walking, turning sharply, sitting down and rising, and making small coördinated movements, while memory of incidents within the previous few hours and estimation of time intervals should be inquired into It is the sum of the conclusions arrived at after such varied inquiries that may justify or negative the diagnosis of drunkenness

The pathological conditions are set out which may simulate alcoholic intoxication and so lead to obviously unfair conditions where an inquiry is conducted in a perfunctory manner Here a warning is given which should hardly be needed by medical men, but which has an extreme importance in law courts especially for the information of juries The report finds that every single symptom due to the consumption of alcoholic liquor may also be assigned to some other pathological condition Sir **James Purves-Stewart** pointed out in a famous address on acute drunkenness delivered two years ago before the Society for the Study of Inebriety[1] that many of the commoner clinical phenomena employed on tests in the recognition of drunkenness are not in themselves tests for alcoholic poisoning, but rather for cerebral, cerebellar, or ponto-bulbar disorders And everyone knows how the presence of mental or nervous disorder, and the effects of drugs, of chemicals, or of shock may cause symptoms indistinguishable save by scientific investigation from those of drunkenness

◆

VORONOFF'S METHOD OF REJUVENATION

Dr Serge Voronoff is an enthusiast whose literary output keeps pace with his surgical work, and "Étude sur la Vieillesse" (1926) is followed by an English publication entitled "The Study of Old Age and My Method of Rejuvenation,"[2] translated by Dr F F Imianitoff The introductory chapters deal with the immortality of unicellular organisms, and the mortality of more highly organised creatures—a mortality which Voronoff attributes, partly, at any rate, to degenerative processes in the endocrine glands during old age He points out that the testis more than any other gland gives evidence of diminished function, for whereas the thyroid of an old man still continues to secrete, the testicles—at least so far as spermatogenesis is concerned—cease to function The diminution in the activity of the sexual glands, according to Voronoff, occurs pari passu with the onset of the signs and symptoms of old age, and the similarity between symptoms of senility and those of testicular insufficiency were, of course, emphasised by Brown-Séquard as long ago as 1869 The arguments employed by Voronoff in favour of the use of testicular grafts are, indeed, strongly reminiscent of those formerly put forward by the advocates of treatment by injection of testicular extract But unfortunately the problem is less simple than Brown-Séquard and Voronoff would lead us to believe The changes in the testes during old age are part of a widespread process affecting the whole body, and there is no reason to regard testicular atrophy and senility as standing in the relationship of cause and effect The real value of Voronoff's book lies not in its "scientific" preamble, but in its account of the practical results obtained from grafts; the value of his work must be determined by clinical results rather than theoretical arguments No longer can it be suggested that his deductions are based on insufficient material He has carried out the operation of grafting in over 1000 animals, and, if the work of other surgeons who have applied his methods is included, in over 600 men

---

[1] The Lancet, 1925, i, 111

[2] London The Gill Publishing Co, Ltd 1926 Pp 155 10s 6d

His experiments have extended over some 13 years, and there has been plenty of opportunity of watching results

In reading the book it is impossible not to be impressed by such cases as that of the senile ram, apparently at the end of his potency in 1918 and still vigorous and sireing lambs in 1925—a result apparently achieved by the use of three testicular grafts inserted in 1918, 1920, and 1923 A weighty argument in favour of this rejuvenation being the direct result of grafting is the fact that one year after the first operation the grafts were removed, their removal being immediately followed by a recrudescence of old age, signs of which again disappeared after the use of the second series of transplants In speaking of man Voronoff suggests that the human organism reacts to grafting in exactly the same way as the ram or the bull In his opinion results have been obtained in the human being as astonishing as those recorded amongst the lower animals What is most surprising is that Voronoff employs heterografts obtained from chimpanzees, and yet the results published in his book appear to be far better than those obtained by Lespinasse, Morris, Lydston, and Kenneth Walker, when employing homografts obtained from human beings Voronoff himself seems somewhat astonished at this, and asks "Is the ape superior to man in the quality of his organs, in having a stronger physical constitution which is less marred by morbid inheritances such as arthritis, alcoholism, syphilis, &c ?" He states that thyroid grafting from simian glands has given him better results than the use of human thyroid And yet it is a well-recognised fact that heterografts taken from animals lower in the scale than chimpanzees are rapidly absorbed In a case described by Kenneth Walker in which he had the opportunity of examining human grafts which had been inserted, according to Voronoff's technique, five months previously, almost complete absorption of the testicular tissue had occurred Voronoff, on the other hand, found that a simian graft examined 15 months after implantation showed complete survival of the epithelial cells of the seminiferous tubules

Interesting as is "The Study of Old Age," it cannot be perused without a feeling of disappointment at the method of presentation We hear too much of the author's successes and too little of his failures No attempt has been made to analyse the thousand cases of animal grafting and the 600 human experiments, and to tabulate the results. In how many of these cases were the results of grafting negative, in how many partial, and in how many completely successful? Was any attempt made in the human cases to find evidence of success other than the statements of the patients, the increase of bodily weight, and the somewhat misleading testimony of the camera? Steinach, in presenting his results, spared no effort to furnish every possible piece of evidence that ingenuity could devise His animals before vasoligature were subjected to searching tests in order to determine their muscular activity, their muscular coordination, their sexual activity, and their intelligence These tests furnish data of great value in arriving at a conclusion as to the effect of the rejuvenation operation Similarly in assessing the results of vasoligature applied to human beings Steinach's followers have produced objective evidence of reactivation Peter Schmidt (Berlin), Knud Sande (Copenhagen), and H Benjamin (New York) have shown that high blood pressure decreases considerably after vasoligature, although it rises somewhat a few months later Again, Wilhelm (Santiago de Chile) has reported that as the result of vasoligature the number of red blood corpuscles and correspondingly the amount of hæmoglobin in the blood is considerably increased This phenomenon explains the distinct improvement in the processes of oxidation after vasoligature which A. Loewy and H Zondek (Berlin) have demonstrated by their measurements of the basal metabolism of different patients before and after operation Wilhelm, in addition to his observations on the blood, has also studied muscular contractility before and after vasoligature and has furnished dynometric measurements showing that the increase in muscular strength amounts to several kilogrammes and is lasting In comparing Steinach's work with that of Voronoff's we are not suggesting that vasoligature gives better results than grafting, the intention is rather to compare the methods that have been adopted by each worker in assessing results, and to emphasise the fact that whereas Steinach and his followers have spared no effort to obtain objective evidence of reactivation, Voronoff has contented himself with subjective evidence supplemented by the doubtful testimony of the camera He writes for the public rather than for the scientist, and this will probably explain why the scientist has on the whole neglected his work Ten cases examined before and after operation with every method of scientific precision are of more value in determining the effect of a graft than a hundred cases operated upon and reported upon, with only the data supplied by Voronoff However much admiration we may feel for his enthusiasm and industry, we cannot but regret that he has not written with that exactitude which is expected of every scientific worker

Annotations.

"Ne quid nimis"

THE END OF THE OUTBREAK OF ANTHRAX AT THE ZOO

THE first part of the story of the recent outbreak of anthrax at the Zoological Gardens is set out in a report presented on Feb 8th to the prosectorial committee of the Zoological Society by Dr. H. Harold Scott, pathologist to the Society It will be remembered that two elephants died within a few days at the end of last year and autopsies were immediately performed Smears taken from the blood and various tissues of Indiarini, the first elephant to die, showed the presence of large, rather square-ended bacilli Anaerobic cultures from the same material grew well, while the aerobic ones did not, this led at first to the inference that the *B pyogenes capsulatus* might be the cause of death At the autopsy on Sundermalah, the second victim, a sore covered by a scab was found on the internal aspect of the right elbow Smears made from the tissues underneath this scab and from the blood and various organs showed numerous bacilli suspicious of anthrax, but not quite typical in size or shape However, cultures and stained sections confirmed the *diagnosis* Prompt steps were taken to examine all the men who had been in contact with either of the animals, for cuts, sores, or spots, although at this stage the cause of death of the first elephant was still unproven Three men were found to have small cuts or fissures on their hands, and another a spot on the face Smears and cultures were put up from these, but, except for a growth of various types of staphylococcus, the results were negative On the same or following day, however, one of these men noticed a spot on his wrist which, when he returned to the Gardens four days later, had developed into a papule becoming vesicular with hæmorrhagic periphery, the whole rather smaller than a threepenny piece Smears and culture revealed the suspected *B anthracis* Since this individual had not come into any contact with Sundermalah, his infection proved that Indiarini also had died from anthrax, masked by a secondary or terminal infection Some six days after the autopsy on the second elephant, the assistant who had helped to perform it found spots on his arm from which the bacillus was recovered, and two other contacts also developed lesions All these cases were sent to St Thomas's Hospital, and their speedy recovery under treatment by Sclavo's serum is recorded by Mr R H Boggon in our columns this week

Several points of interest emerge from the outbreak, which was confined within such narrow limits by the prompt action of those in charge of the departments concerned It is clear that infection may readily occur by a hair follicle when all care has been taken to seal cuts, fissures, or more open wounds; one of the assistants, who at the second autopsy gave himself a fairly deep cut, which was vigorously treated, showed no sign of infection, whereas the lesions in the affected persons appear all to have started in hair follicles The incubation period was as much as six days in the two assistants who were exposed to infection only on one known occasion It is noteworthy also that the initial sore is quite painless and, as Mr Boggon points out, is only distinguishable from a septic spot by the history, the dark centre, and the surrounding pallor The gratifying response of all the patients to serum injection made discussion of treatment superfluous, since serum may not always be quickly available in remote districts, we would call attention to the excellent results achieved in Germany and in South Africa by the intravenous injection of salvarsan [1]

There remains the mystery as to the source of the anthrax infecting the elephants In neither case did the intestines show any inflammation, and the probability of the animals having been infected by mouth is anyhow slight Sections of the portal veins contain practically no bacilli, whereas those of the branches of the hepatic artery are crowded with them Dr Scott explains this contrast on the assumption that the systemic vessels carried the infection from the skin or lungs, and that infection did not gain entrance through the alimentary tract In spite of the absence of signs of intestinal infection, the oil cake supplied to the elephants was examined bacterially, with negative results Cultures made from fissures in the skin of the other five elephants in the Zoo also proved negative, and all these animals remain well; nor did examination of the pig oil with which the elephants are rubbed from time to time yield any information The cooperation of the Ministry of Health was sought immediately, but so far all efforts to trace the source of infection have failed This is of less moment since the outbreak was so swiftly recognised as to be confined to immediate contacts with the animals The value to the Zoological Society and to the public of a medically qualified superintendent of the Gardens and a pathologist of repute to superintend the autopsies is manifest, and we congratulate the Society on the vigilance of its staff

VERTIGO IN EPIDEMIC ENCEPHALITIS

IN the December number of *Brain* and, more briefly in a discussion at the Manchester Medical Society which we report on page 438 of this issue, Dr R I Poston draws attention to the occurrence of vertigo with other signs of vestibular disorder as an important symptom in epidemic encephalitis, or encephalitis lethargica This manifestation of the disease, he says, has not been thoroughly studied in this country. Quoting Gerlier's account of an "epidemic of paralysing vertigo" which occurred near Geneva in 1886 and was characterised by vertigo, muscular relaxation and paralysis, and ocular disturbances, especially ptosis, and recalling a somewhat similar disease ("Kubisagari") which seemed to be endemic in parts of Japan in 1887, Dr Poston puts the interesting question whether the pandemic of encephalitis lethargica of the last decade arose by spread of infection from earlier cases in Japan or Geneva In the 1921 epidemic in Alsace-Lorraine, Barré and Reys were impressed by the great number of patients who complained of vertigo, loss of equilibrium, and lateropulsion, and they regarded these labyrinthine phenomena as cardinal symptoms, second only in importance to the more common oculomotor manifestations The evidence of labyrinthine involvement which they obtained by means of the caloric and rotary tests showed that such a lesion was much more frequent than would be suspected from the patient's history, and they believe that vestibular phenomena are so frequent as to be worth searching for in every case of encephalitis Dr Poston quotes pathological evidence that the vestibular and neighbouring nuclei may be affected in epidemic encephalitis, and suggests that interference with vestibular function may account for many, if not all, of the oculomotor phenomena of the disease He mentions ten cases in which he found that the vestibular tests gave abnormal results, and concludes that the possibility of a previous, current, or impending attack of epidemic encephalitis should always be considered seriously in the differential diagnosis of cases showing disordered equilibration His full description of the very sensitive method of applying caloric and galvanic labyrinthine tests elaborated by Babinski, Weill, and Amado, will be of special interest to otologists Now that attention has been directed to vestibular symptoms in this disease, it is probable that they will be looked for, and found, more often than at present

DIAPHRAGMATIC HERNIA.

AMONG the interesting exhibits at the meeting of the Anatomical Society on Feb 4th were examples of varieties of diaphragmatic hernia (two occurring in cats), shown by Lady Briscoe and by Dr R H Hunter, while Dr. Beattie, of the Zoological Society, gave a communication on the same abnormality occurring in the lower animals The subject of diaphragmatic hernia has great clinical interest, and would bear investigation by competent observers as to the forms, extent, and relative positions of the herniated parts and the corresponding apertures Developmentally, also, more light might be thrown on the nature and position of the underlying abnormality in congenital cases The primitive cœlomic cavity in which the lung bud forms is directly continuous with that of the abdomen, but the secondary cavity within which it enlarges is another thing. This last has no direct connexion with the abdomen save through the remnant of the primitive cavity, which quickly closes But diaphragmatic herniæ are not by any means always a sequel of an unclosed opening of this sort, for they may take place through the œsophageal opening or through spaces elsewhere All these seem to admit of being brought into line under systematic investigation Some of the more monstrous kind, such as that shown by Lady Briscoe, where the liver was enveloped by the general pericardial sac, are apparently more straightforward developmentally than others which would seem simpler We must await the proper classification of these important anomalies

A ROUTINE TREATMENT FOR INFLUENZA

THE outlines of a scheme for the treatment of uncomplicated influenza appear in the *Munchener Medizinische Wochenschrift* for Feb 4th The author, Prof Trumpp, believes in supervising details which are often left to the judgment of relatives, and begins by laying down the conditions for nursing The sick-room, he points out, should be the sunniest and airiest in the house The patient should not face the light, and if the wall opposite him is too bright it should be draped with some dull material, though darkening of the whole room is undesirable A window should be open at all times to an extent that will bring the room temperature to 60° F by day and somewhat less by night. The better the ventilation the sooner the headache and malaise—and the pulmonary complications, if there are any—will depart Warm, dry rooms are anathema to Prof Trumpp A woollen bed-jacket or sweater guards against sudden chill, especially at night, and the play of draughts on the body is prevented by using only one door in the room, and by placing the bed so that it is not on any line of the triangle whose sides join the window, door, and fire Pillows should be firm, so as not to wrap an already suffering head, and the head end of the bed should be raised on blocks For uncomplicated cases Prof. Trumpp has a favourite mixture consisting of camphor. benzoic acid. and pyramidon The first and third of these he regards as bactericidal; camphor. besides being a heart stimulant. is an expectorant; pyramidon reduces the temperature, and benzoic acid is an adjuvant to camphor. The amount given is 0 01 to 0 05 g of camphor and the same quantity of benzoic acid, with 0 05 to 0·1 g. of pyramidon (according to age) in 0 5 g. lactose. this dose being taken three times a day in milk or water. Elimination of toxins by the skin and bowels plays an important part in Prof. Trumpp's treatment He disapproves of cold applications except an occasional cool pack for the feet but for patients with sound hearts recommends a daily bath at 105° F. lasting a minute with brisk gloving. After a vigorous rub-down with a towel the patient is whisked back to bed and given a glass of strong hot toddy. An enema at 75° F. should precede the first bath, being held for a minute and a half; besides acting as an aperient it also cools the body Laxative drugs, according to Prof Trumpp are better avoided. and he advises that fruit should be given instead, also recommending wholemeal bread in the diet The sceptical may feel doubtful whether the campaign in favour of ' roughage " in bread need thus be carried into the sick-room of patients with acute fever. and may accordingly prefer to employ aperients whose dose can be more easily regulated Prof Trumpp has no objection to the patient fasting for a day or two if he wishes, but suggests that to stimulate appetite the teeth should be cleaned every two hours and the mouth rinsed with plain water. Cereals and puddings may be given in moderate quantities, but the use of meat and meat broths is discouraged. Prof. Trumpp's views have, of course much in common with current practice in this country. They are chiefly interesting, perhaps, because he has worked out a comprehensive plan of treatment for all uncomplicated cases Very many practitioners must have similar plans; but, on the other hand, it is not uncommon for patients with mild influenza to undergo unnecessary discomfort, not because their medical attendant can only pay them a hurried visit but because he has not thought out a scheme of treatment which can be rapidly applied in a large proportion of his cases

THE HISTORY OF HARLEY STREET

THE Royal Society of Medicine held an enjoyable social evening on Feb. 21st, when Sir James and Lady Berry welcomed a large gathering of Fellows and guests In an address entitled Topographical and Medical Notes on Harley Street Mr. Percy Flemming gave an absorbing account of the process by which the medical profession took over the part of Marylebone that lies between Regent's Park and Wigmore-street He pointed out that the present phase of London's growth—the incorporation of surrounding towns and villages—began about 180 years ago Marylebone was one of these outlying villages but the growth of the city has long since obliterated the Fleet the Westbourne. and the Tyburn streams which once formed its boundaries These rivers now flow imprisoned in pipes under the roaring traffic from Hampstead to the Thames West Bourne and its overhead conduit in Sloane-square Station has recently been immortalised by *Punch* · Fleet or Hole Bourne is now a sewer under Ludgate-circus and Ty Bourne runs near the house of the Royal Society of Medicine under various passages and courts near Marylebone-lane. which was its left bank At the time of the Domesday Book Marylebone was unknown. and the land was part of Tyburn Manor The Harley-street district was the scene of public health enterprise in very early days for in 1236 the City authorities. in their search for a safe water-supply discovered the Tyburn and piped it where it was reinforced by a spring just in the dip by Stratford-place The critical time for the amenities of the place came in the reign of James I who sold Tyburn Manor. but kept what is now Regent s Park for his own use, with the result that this invaluable oasis is still in the safe hands of the Crown. A scheme was later put forward for dividing the area into building sites This evil was fortunately averted. but the southern end was partly built over. and one side of Harley-street is Crown property. and the other side privately owned to this day. The park was let out to farmers and there is contemporary evidence of its use by physicians for a kind of spa treatment. For instance. in 1772 a lady of 'Great Portland-street the patient of a Dr. Armstrong. was advised to take an early walk every morning and to drink milk at a farmhouse situated near Yard Gate Her son mentions the "elegant mansions" of Cavendish-square as the border of the town and the open country. This and its neighbouring squares were laid out in 1718. and soon became the home of the aristocracy. There would almost certainly have been a sprinkling of general practitioners here then but the consultant district was in the City. round about Broad-street. New Bridge-street, and Finsbury-circus. The migration westward halted for a space in Bloomsbury. and for some time after that the favoured spot was Hanover-square Only the later 'thirties saw the start of the Harley-street district. when a few consultants moved to Cavendish-square. The numbers slowly increased until in the 'sixties Harley-street began to be regarded as the right place for a consultant to live Sir William Jenner was actually the first to arrive; he entered No 8 in 1851. Mr. Flemming concluded by remarking on a trickle of medical men across Marylebone-road into Regent's Park. and speculated whether this foreshadowed a general migration He illustrated his lecture with some interesting prints and maps of old Marylebone, the originals of which. with many others were displayed in the Society's Library. He has set future speakers a high standard to live up to for not only has he collected his material with expert patience and skill, but he possessed the ability to display it with humour and feeling. As long as such good fare is provided at the Society s social evenings their great popularity will never wane.

TREATMENT OF RINGWORM IN YOUNG CHILDREN

THOUGH ringworm of the scalp can generally be cured in course of time by the conscientious application of ointments. it is agreed that measures against the organism are more likely to be successful if the infected hair can be completely removed as the first step in the treatment For this purpose it is usual to give a nicely calculated dose of X rays, and the results are. on the whole. satisfactory. Most dermatologists, however refrain from irradiating the scalp where the patients are small children, and with young subjects it is the current practice to dispense with epilation and to rely on the action of time-honoured remedies This is undoubtedly inconvenient, and an attempt has lately been made to overcome the difficulties inherent in giving infants an epilatory dose of X rays. In the *British Journal of Dermatology and Syphilis* for last December. Dr J. M H. Macleod describes a special couch and immobilising cap designed by Mr. S Cochrane Shanks radiologist at Charing Cross Hospital for the treatment of ringworm of the scalp in children under 3 years of age The article is somewhat technical and its main details would be likely to interest only the actual operator, but the summary of results in tabular form deserves attention Of a total of 276 patients 52 were between 1 and 2 years of age. and 224 between 2 and 3 In none of them was there a single serious mishap such as a resulting burn or permanent alopecia. nor was a second irradiation required in a single case. The results as regards technique are therefore beyond criticism and there is no reason to suppose that damage is caused to the brain by any action of the rays But the fact remains that young children may be frightened by the noise and sparking of the apparatus, and if to this potential cause of alarm is added forcible constraint by an immobilising cap, and the use of a special couch on which the child is "strapped after being rolled tightly in a blanket," we have a combination of impressions which may fairly be described as terrifying, and which, if they do not produce an immediate effect, may well be stored up as interesting material for the psycho-analysts of a future generation By a coincidence it happens that the claims of an alternative method of epilation are at present being put forward We recently reported[1] a meeting of the Section of Medicine at the Royal Academy of Medicine in Ireland, at which Dr Maurice Drummond demonstrated three cases in which the hair had been removed by single doses of thallium acetate, and last week we published[2] a more comprehensive account of the procedure, based on 24 cases, by Dr G B Dowling and Dr R. Kelman It is unnecessary to repeat the details of technique which are given in these reports The use of thallium acetate for producing baldness is by no means new, for Sabouraud, of Paris, experimented with it 30 years ago and advised against its employment as being both uncertain and unsafe In the meantime, however, Prof Buschke, of Berlin, has worked out a standard dose of from 8 to 9 mg per kg of body-weight, and this he describes as free from danger and almost invariably effective in its epilating action He lays great stress, however, on the necessity for using only a chemically pure and biologically standardised preparation, and this he obtains from one firm of chemists only Buschke's work has been repeated on a large scale in the United States and also in Mexico, where there was a shortage of X ray equipment during the late war. The claims put forward have been less cautious than those of Dr Dowling, who freely admits that he has noticed mild toxic symptoms in a number of cases ; in a discussion at the Section of Dermatology of the Royal Society of Medicine (which we report on p 438 of this issue) he goes so far as to suggest that it might be well for patients to remain in bed for about three weeks after taking their single dose of thallium The preparation used by Dr Dowling and Dr. Kelman was not biologically standardised, but it seems unlikely that even standardisation can wholly prevent undesirable toxic symptoms arising from administration of a drug which is in reality used for its poisonous effect on the hairs or the nerves supplying them Possibly, as Dr. H C Semon suggests, some means may be found of neutralising objectionable toxicity In the meantime it is interesting to note the experiences of Dr S Monckton Copeman, who gave the Section of Dermatology a description of the effects of small repeated doses of thallium acetate on patients suffering from cancer, and those of H R Olivier, in France, who has recently reported[3] on chronic intoxication of animals with the drug Olivier finds that prolonged administration to rats engenders a sort of refractive state in which hair is eventually replaced, and he also reports the production of benign papillomatous tumours of the stomach It may be thought that these results are barely relevant since when the drug is used for children not more than a single dose is given Their merit, however, is that they suggest extreme caution Thallium is a poison with physiological effects resembling those of lead, and though ringworm of the scalp is an economic nuisance it in no way endangers life Cases of idiosyncrasy may possibly be met, and even in ordinary cases the treatment requires great care It will be very unfortunate if thallium comes into general use or misuse before it has been properly tested under the best conditions

EARLY AMERICAN SURGERY.

The Hunterian Society made a wise choice when they asked Prof J M T Finney of Baltimore to deliver the Hunterian Lecture for 1927 Prof Finney's recent visit was welcome not only because he is well known in England for his work at Johns Hopkins Hospital and for distinguished service with the American Expeditionary Force during the late war, but also because he represents that section of opinion in the United States which looks for and finds community rather than antagonism in the aims and ethics of Americans and English This attitude was expressed when he chose to address the Hunterian Society on the Influence of John Hunter on Early American Surgery, a subject which not only gave him a chance of paying high tribute to a great surgeon but also of laying emphasis—where it should be laid—on the common origin of our traditions In the present issue of The Lancet (p 469) we conclude the publication of Prof Finney's lecture, and those who read it will find an able summary of the lives and work of some of the surgeons who flourished in the American "Hunterian Era" How directly many of these men were influenced by Hunter will seem surprising to those who do not know that large numbers of young Americans came to Europe—even soon after the War of Independence—to learn their trade in the continental and British schools Some of the more notable were pupils of the Hunters in London and even members of their household Of these an imporant example was William Shippen, jun , afterwards a founder of the Philadelphia Medical College, from whose diary Prof Finney makes some quotations which are especially interesting as the period covered is one which is but little described in the books dealing with Hunter's life Hunter's successful work and the record of his life are, however, fairly familiar to the medical profession in this country, and perhaps the special merit of Prof Finney's lecture is that it describes for his English hearers some of the achievements—less often recognised—which stand to the credit of our surgical predecessors in the New World

THE SALE OF ULTRA-VIOLET LAMPS

A pronouncement on the sale of apparatus for the generation of ultra-violet rays has just been made by the Council on Physical Therapy of the American Medical Association [1] The Council states that distribution of these generators to the public for self-treatment is undesirable on the following grounds —

1 The uninformed public could not take the proper precautions in administering treatments and, as a result, severe general burns or grave injury to the eyes might ensue.

2 Those not familiar with the possibilities of such apparatus would be led to place unwarranted confidence in the therapeutic value of such treatment by the claims that might be made in the literature advertising such generators, and to undertake to treat serious conditions not amenable to such treatment

3 The unrestricted possession of such therapeutic means would tend to deprive people of expert diagnosis by encouraging them to make self-diagnoses

4 Such practice would encourage the sale of useless and fraudulent lamps which would be advertised as generators of ultra-violet rays, since the public would have no means at its disposal to determine the quality or quantity of the radiant energy emitted by such lamps

For these reasons, says the Council, the sale or the advertising for sale, directly to the public, of a generator of ultra-violet energy is detrimental to the public welfare, and apparatus made by firms whose policy is thus detrimental will not in future be included in the official list of accepted devices for physical treatment Medical men generally will support this action The apparent ease with which ultra-violet apparatus can be manipulated may lead people to think that they can therefore give themselves treatment Needless to say, this impression would be fostered by traders anxious only to increase their output There is, however, a good case here for protecting the public from the dangers of ultra-violet rays During the next few years some late effects of overdosage (such as cataract) may become apparent —just as occurred in the case of X ray therapy It is to be hoped that the lead given by the American Medical Association will be followed by other powerful medical bodies

THE ROYAL SOCIETY

THE list of candidates for the Fellowship of the Royal Society who have been recommended by the Council for election this year, includes many names familiar to our readers Prof E V Appleton holds the Wheatstone Chair of Physics at King's College in the University of London, Dr T Graham Brown, professor of physiology in the Welsh National School of Medicine, has explored the spinal reflex in decerebrate mammals; while Mr R H Burne, Physiological Curator of the Museum of the Royal College of Surgeons of England, is known for his work on the comparative anatomy of molluscs, fishes, and mammals Dr James Chadwick is engaged in the study of radio-activity in the Cavendish Laboratory at the University of Cambridge, Prof James Kendall holds the Chair of Chemistry in Columbia University, New York Dr P P Laidlaw, formerly Gordon lecturer in pathology at Guy's Hospital Medical School, is now on the staff of the National Institute at Hampstead His recent activities in the investigation of distemper, as also those of his colleague at the Institute, Mr Otto Rosenheim on the parent substance of vitamin D, are referred to in another column The more distant universities are honoured in the persons of Mr A A Lawson, formerly lecturer at Glasgow, and now professor of botany in Sydney, and Mr Meghnad Saha, professor of physics at Calcutta Mr. J S B Stopford, professor of anatomy in the University of Manchester and Dean of the Medical Faculty, in addition to purely academic research, has initiated work on the regeneration of nerves with results which proved of notable value in neurological surgery during and after the war Finally, Dr C M Wenyon, director-in-chief of the Wellcome Bureau of Scientific Research, is responsible for differentiation of intestinal parasites which has greatly facilitated the diagnosis of protozoal infections

HEALTH ORGANISATION OF THE LEAGUE OF NATIONS

UNDER the auspices of the Health Organisation of the League of Nations a further visit to Great Britain of public health officials from 12 different countries began on Monday last Representatives of Belgium, China, Czecho-Slovakia, France, Germany, Greece Italy Lithuania, Poland, Rumania, Sweden, and Jugo Slavia are taking part in the present interchange which will last six weeks The first week is being spent in London, in visits to the various institutions of the Metropolitan Asylums Board in connexion with the control of infectious diseases, and in the study of London water-supply and housing schemes Next week the public health officials will split up into groups to visit ports such as Liverpool and Glasgow, large industrial centres such as Birmingham and Bradford, a representative residential borough adjoining London—Hornsey has been selected—and certain rural areas in Berkshire The officials will later reassemble in London for the final week which will include inspection of meat and food markets, port sanitation, and visits to various institutions in connexion with medical research, eugenics, industrial psychology, tropical, naval and military hygiene, bacteriological laboratories, and the like The party will probably leave England on April 2nd and meet again in Geneva for the final conference which includes a brief study of the working of the League and in particular, of its Health Organisation Practically all countries, including the United States, Russia and Turkey, as well as the Members of the League, take part in these interchanges, which are attended by roughly 100 medical officers a year, and are carried out with the financial assistance of the Rockefeller Foundation. This is the fifth occasion on which a number of foreign doctors have been here to study British public health services, and similar interchanges have taken place in most European countries, in South and Central America, the United States, Canada, West Africa, and Japan

Colonel John Graham Martin, M D, has been appointed honorary physician to the King This reward comes after long years of meritorious service in the Territorial Army Medical Corps, in which Colonel Martin is now A D M S of the 55th (West Lancashire) Division Dr Martin, who practises in Liverpool, saw service in the South African War as a civil surgeon and in the European War, when he attained his present position It is understood that this is the first time this honour has been granted to a Territorial officer

The Services.

ROYAL NAVAL MEDICAL SERVICE

Surg -Lt J W Tighe to be Surg -Lt -Comdr

Surg -Comdr W R Harrison is placed on ret. list with rank of Surg -Capt

ROYAL NAVAL MEDICAL RESERVE

Prob Surg -Sub-Lts to be Surg -Sub-Lts H G Ungley and D S Buchanan

ROYAL ARMY MEDICAL CORPS

Lt -Col P G Easton retires on ret pay

Maj J J H Beckton is placed on the half pay list on account of ill-health

Temp Capt S E Elphick relinquishes his commn on account of ill-health, and retains the rank of Capt

Lt (on Prob) R V Franklin, from the secd list, is restd to the estabt

Lts (on prob) confirmed in their rank F P M Anderson, J D Borham, P F Palmer, D Bluett, C E Eccles, F M Collins, J. A Chapel

MILITIA

Maj F Jefferson relinquishes his commn and retains the rank of Maj

TERRITORIAL ARMY

The King has approved of the following appointment —To be Honorary Physician to His Majesty Col J G Martin, 55th (W Lanc) Div, in succession to Col G H Edington (ret)

Capt A H Fullerton to be Maj (Prov), and Lts W Simpson, R N Craig (Prov), and R S Creed to be Capt (Prov)

INDIAN MEDICAL SERVICE

The King has approved the retirement of Lt -Col W D H Stevenson

Lts Madhav Krishna Kelavkar, Gurdial Singh Gill, and Ranjit Sen to be Capts

Pran Nath to be Temp Lt

LEEDS PENSIONS HOSPITAL.—The new Ministry of Pensions Hospital at Chapel Allerton is now practically complete and will be opened next month The nucleus of the institution, which is described as the finest Ministry of Pensions Hospital in the country, was Gledhow Grove, the former residence of Mr F J Kitson, which has been converted into administrative headquarters The new buildings are of an artificial stone composed of washed gravel, cement, and sand, of local manufacture, now used for the first time on a large scale, the whole of the timber comes from the Dominions In addition to the usual departments, the buildings, which will hold 260 patients, include a recreation hall, a gymnasium, tennis courts, football ground, and recreational workshops which will be rented by firms making artificial limbs there is no reason to suppose that damage is caused to the brain by any action of the rays But the fact remains that young children may be frightened by the noise and sparking of the apparatus, and if to this potential cause of alarm is added forcible constraint by an immobilising cap, and the use of a special couch on which the child is "strapped after being rolled tightly in a blanket," we have a combination of impressions which may fairly be described as terrifying, and which, if they do not produce an immediate effect, may well be stored up as interesting material for the psycho-analysts of a future generation By a coincidence it happens that the claims of an alternative method of epilation are at present being put forward We recently reported[1] a meeting of the Section of Medicine at the Royal Academy of Medicine in Ireland, at which Dr Maurice Drummond demonstrated three cases in which the hair had been removed by single doses of thallium acetate, and last week we published[2] a more comprehensive account of the procedure, based on 24 cases, by Dr G B Dowling and Dr R Kelman It is unnecessary to repeat the details of technique which are given in these reports The use of thallium acetate for producing baldness is by no means new, for Sabouraud, of Paris, experimented with it 30 years ago and advised against its employment as being both uncertain and unsafe In the meantime, however, Prof Buschke, of Berlin, has worked out a standard dose of from 8 to 9 mg per kg of body-weight, and this he describes as free from danger and almost invariably effective in its epilating action He lays great stress, however, on the necessity for using only a chemically pure and biologically standardised preparation, and this he obtains from one firm of chemists only Buschke's work has been repeated on a large scale in the United States and also in Mexico, where there was a shortage of X ray equipment during the late war. The claims put forward have been less cautious than those of Dr Dowling, who freely admits that he has noticed mild toxic symptoms in a number of cases ; in a discussion at the Section of Dermatology of the Royal Society of Medicine (which we report on p 438 of this issue) he goes so far as to suggest that it might be well for patients to remain in bed for about three weeks after taking their single dose of thallium The preparation used by Dr Dowling and Dr Kelman was not biologically standardised, but it seems unlikely that even standardisation can wholly prevent undesirable toxic symptoms arising from administration of a drug which is in reality used for its poisonous effect on the hairs or the nerves supplying them Possibly, as Dr. H C Semon suggests, some means may be found of neutralising objectionable toxicity In the meantime it is interesting to note the experiences of Dr S Monckton Copeman, who gave the Section of Dermatology a description of the effects of small repeated doses of thallium acetate on patients suffering from cancer, and those of H R Olivier, in France, who has recently reported[3] on chronic intoxication of animals with the drug Olivier finds that prolonged administration to rats engenders a sort of refractive state in which hair is eventually replaced, and he also reports the production of benign papillomatous tumours of the stomach It may be thought that these results are barely relevant since when the drug is used for children not more than a single dose is given Their merit, however, is that they suggest extreme caution Thallium is a poison with physiological effects resembling those of lead, and though ringworm of the scalp is an economic nuisance it in no way endangers life Cases of idiosyncrasy may possibly be met, and even in ordinary cases the treatment requires great care It will be very unfortunate if thallium comes into general use or misuse before it has been properly tested under the best conditions

EARLY AMERICAN SURGERY.

THE Hunterian Society made a wise choice when they asked Prof J. M T Finney of Baltimore to deliver the Hunterian Lecture for 1927 Prof Finney's recent visit was welcome not only because he is well known in England for his work at Johns Hopkins Hospital and for distinguished service with the American Expeditionary Force during the late war, but also because he represents that section of opinion in the United States which looks for and finds community rather than antagonism in the aims and ethics of Americans and English This attitude was expressed when he chose to address the Hunterian Society on the Influence of John Hunter on Early American Surgery, a subject which not only gave him a chance of paying high tribute to a great surgeon but also of laying emphasis—where it should be laid—on the common origin of our traditions In the present issue of THE LANCET (p 469) we conclude the publication of Prof Finney's lecture, and those who read it will find an able summary of the lives and work of some of the surgeons who flourished in the American "Hunterian Era" How directly many of these men were influenced by Hunter will seem surprising to those who do not know that large numbers of young Americans came to Europe—even soon after the War of Independence—to learn their trade in the continental and British schools Some of the more notable were pupils of the Hunters in London and even members of their household Of these an imporant example was William Shippen, jun , afterwards a founder of the Philadelphia Medical College, from whose diary Prof Finney makes some quotations which are especially interesting as the period covered is one which is but little described in the books dealing with Hunter's life Hunter's successful work and the record of his life are, however, fairly familiar to the medical profession in this country, and perhaps the special merit of Prof Finney's lecture is that it describes for his English hearers some of the achievements—less often recognised—which stand to the credit of our surgical predecessors in the New World

THE SALE OF ULTRA-VIOLET LAMPS

A PRONOUNCEMENT on the sale of apparatus for the generation of ultra-violet rays has just been made by the Council on Physical Therapy of the American Medical Association.[1] The Council states that distribution of these generators to the public for self-treatment is undesirable on the following grounds :—

1 The uninformed public could not take the proper precautions in administering treatments and, as a result, severe general burns or grave injury to the eyes might ensue.

2 Those not familiar with the possibilities of such apparatus would be led to place unwarranted confidence in the therapeutic value of such treatment by the claims that might be made in the literature advertising such generators, and to undertake to treat serious conditions not amenable to such treatment

3 The unrestricted possession of such therapeutic means would tend to deprive people of expert diagnosis by encouraging them to make self-diagnoses

4 Such practice would encourage the sale of useless and fraudulent lamps which would be advertised as generators of ultra-violet rays, since the public would have no means at its disposal to determine the quality or quantity of the radiant energy emitted by such lamps

For these reasons, says the Council, the sale or the advertising for sale, directly to the public, of a generator of ultra-violet energy is detrimental to the public welfare, and apparatus made by firms whose policy is thus detrimental will not in future be included in the official list of accepted devices for physical treatment Medical men generally will support this action The apparent ease with which ultra-violet apparatus can be manipulated may lead people to think that they can therefore give themselves treatment Needless to say, this impression would be fostered by traders anxious only to increase their output. There is however, a good case here for protecting the public from the dangers of ultra-violet rays During the next few years some late effects of overdosage (such as cataract) may become apparent —just as occurred in the case of X ray therapy. It is to be hoped that the lead given by the American Medical Association will be followed by other powerful medical bodies

THE ROYAL SOCIETY.

THE list of candidates for the Fellowship of the Royal Society who have been recommended by the Council for election this year, includes many names familiar to our readers. Prof. E V. Appleton holds the Wheatstone Chair of Physics at King's College in the University of London; Dr. T. Graham Brown. professor of physiology in the Welsh National School of Medicine has explored the spinal reflex in decerebrate mammals; while Mr. R. H. Burne, Physiological Curator of the Museum of the Royal College of Surgeons of England. is known for his work on the comparative anatomy of molluscs, fishes. and mammals. Dr. James Chadwick is engaged in the study of radio-activity in the Cavendish Laboratory at the University of Cambridge; Prof. James Kendall holds the Chair of Chemistry in Columbia University, New York. Dr. P. P. Laidlaw, formerly Gordon lecturer in pathology at Guy's Hospital Medical School, is now on the staff of the National Institute at Hampstead. His recent activities in the investigation of distemper. as also those of his colleague at the Institute. Mr Otto Rosenheim on the parent substance of vitamin D, are referred to in another column The more distant universities are honoured in the persons of Mr A. A. Lawson formerly lecturer at Glasgow, and now professor of botany in Sydney, and Mr. Meghnad Saha. professor of physics at Calcutta Mr. J. S B Stopford, professor of anatomy in the University of Manchester and Dean of the Medical Faculty, in addition to purely academic research, has initiated work on the regeneration of nerves with results which proved of notable value in neurological surgery during and after the war Finally. Dr. C. M Wenyon. director-in-chief of the Wellcome Bureau of Scientific Research. is responsible for differentiation of intestinal parasites which has greatly facilitated the diagnosis of protozoal infections

HEALTH ORGANISATION OF THE LEAGUE OF NATIONS

UNDER the auspices of the Health Organisation of the League of Nations a further visit to Great Britain of public health officials from 12 different countries began on Monday last Representatives of Belgium. China, Czecho-Slovakia. France, Germany, Greece Italy. Lithuania. Poland, Rumania. Sweden, and Jugo Slavia are taking part in the present interchange which will last six weeks The first week is being spent in London, in visits to the various institutions of the Metropolitan Asylums Board in connexion with the control of infectious diseases and in the study of London water-supply and housing schemes. Next week the public health officials will split up into groups to visit ports such as Liverpool and Glasgow, large industrial centres such as Birmingham and Bradford. a representative residential borough adjoining London—Hornsey has been selected—and certain rural areas in Berkshire. The officials will later reassemble in London for the final week. which will include inspection of meat and food markets port sanitation, and visits to various institutions in connexion with medical research eugenics, industrial psychology. tropical, naval and military hygiene, bacteriological laboratories. and the like The party will probably leave England on April 2nd and meet again in Geneva for the final conference. which includes a brief study of the working of the League and in particular, of its Health Organisation. Practically all countries, including the United States Russia and Turkey, as well as the Members of the League, take part in these interchanges which are attended by roughly 100 medical officers a year. and are carried out with the financial assistance of the Rockefeller Foundation. This is the fifth occasion on which a number of foreign doctors have been here to study British public health services, and similar interchanges have taken place in most European countries, in South and Central America, the United States, Canada, West Africa, and Japan

Colonel John Graham Martin. M D.. has been appointed honorary physician to the King. This reward comes after long years of meritorious service in the Territorial Army Medical Corps, in which Colonel Martin is now A D M.S of the 55th (West Lancashire) Division. Dr. Martin who practises in Liverpool saw service in the South African War as a civil surgeon and in the European War, when he attained his present position It is understood that this is the first time this honour has been granted to a Territorial officer.

The Services.

ROYAL NAVAL MEDICAL SERVICE

Surg-Lt. J. W. Tighe to be Surg-Lt.-Comdr.

Surg-Comdr. W R. Harrison is placed on ret. list with rank of Surg-Capt.

ROYAL NAVAL MEDICAL RESERVE.

Prob Surg-Sub-Lts. to be Surg-Sub-Lts. H. G Ungley and D S. Buchanan.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. P. G Easton retires on ret. pay.

Maj J. J H. Beckton is placed on the half pay list on account of ill-health.

Capts. to be Majs.. D S Martin, W. L E Reynolds (Prov), W. K. Campbell (Prov.), and C G G Keane.

Capt. S J. C Holden to be Maj

Capt. A. J. Bado R.A.M.C, to be Divl Adjt. 43rd (Wessex) Div, vice Capt. A. Rodd to half pay.

Temp Capt. S. E Elphick relinquishes his commn. on account of ill-health and retains the rank of Capt.

Lt. (on Prob) R. V. Franklin, from the secd. list, is restd. to the estabt

Lts. (on prob) confirmed in their rank: F. P. M Anderson, J D Borham, P F Palmer, D Bluett, C E Eccles, F. M. Collins, J. A. Chapel.

MILITIA.

Maj F Jefferson relinquishes his commn. and retains the rank of Maj.

TERRITORIAL ARMY.

The King has approved of the following appointment:— To be Honorary Physician to His Majesty: Col. J G. Martin, 55th (W Lanc.) Div., in succession to Col. G. H Edington (ret.)

Capt. A. H. Fullerton to be Maj (Prov.), and Lts. W. Simpson, R N. Craig (Prov.), and R. S Creed to be Capt. (Prov.)

INDIAN MEDICAL SERVICE

The King has approved the retirement of Lt.-Col. W. D H. Stevenson.

Lts Madhav Krishna Kelavkar, Gurdial Singh Gill, and Ranjit Sen to be Capts.

Pran Nath to be Temp Lt.

LEEDS PENSIONS HOSPITAL.—The new Ministry of Pensions Hospital at Chapel Allerton is now practically complete and will be opened next month. The nucleus of the institution which is described as the finest Ministry of Pensions Hospital in the country. was Gledhow Grove, the former residence of Mr. F. J. Kitson, which has been converted into administrative headquarters. The new buildings are of an artificial stone composed of washed gravel, cement and sand of local manufacture, now used for the first time on a large scale. the whole of the timber comes from the Dominions. In addition to the usual departments, the buildings, which will hold 260 patients, include a recreation hall, a gymnasium, tennis courts, football ground, and recreational workshops which will be rented by firms making artificial limbs.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCXII —TREATMENT OF POISONING.

IN the treatment of poisoning, acute and chronic, pharmacology must be the keynote of procedure, common sense goes a long way, but without a sound knowledge of the action of poisons and drugs, and a moderate armamentarium, the practitioner may lose the patient

(1) ACUTE POISONING

The steps to be taken are three · first, to get rid of the poison out of the system, secondly, to neutralise or render harmless what cannot be removed, and thirdly, to meet the damage already done and to mitigate general symptoms It is obvious that these steps will frequently be taken simultaneously

Elimination of the Poison

Are there any cases in which the attempt to eliminate the poison should not be made ? It is generally stated that emetics and the stomach-tube are to be avoided in corrosive poisoning, but it is fairly evident that, where the situation is such that the stomach cannot be emptied, the death warrant is signed It is, however, of no use to pass a stomach-tube on a dying man In any case, then, where there is a reasonable opportunity, we must use either stomach-tube or emetic But emetic and stomach-tube are by no means antagonistic I have seen cases where an emetic has been given and the attempt to pass the stomach-tube shortly afterwards has promptly determined vomiting; also cases where, after washing out, an emetic left in the stomach has cleared the residue, a quantity by no means negligible With unconscious patients in narcotic poisoning emetics cannot be swallowed and, even when administered hypodermically, act badly Here the stomach-tube is essential, but it is just in these cases that the passage of the tube is extraordinarily difficult Taking poisoning cases generally, it may be said that it is best to use the tube and wash the stomach out well

Details of the use of the stomach-tube are hardly necessary The apparatus needs a long piece of tubing and a funnel, which is raised or depressed according as the water is to flow into or out of the stomach The use of a gag, the finger passed along the tongue to the back of the pharynx, and the tube passed along this usually made the insertion easy A movement of the head slightly forwards may ease the passage After the insertion it is safer to pour water into the stomach before withdrawing the contents Substitutes for a specially manufactured stomach-tube may have to be found I have heard of one case of strychnine poisoning in a child where life was saved by the expedient of cutting off the nozzle of a Higginson's syringe and passing the tube as far as it would reach and of driving water into the stomach till it flowed back outside the tube

Emetics may be divided into two classes, those stimulating the vomiting centre and those irritating the gastric mucous membrane, so that vomiting is caused reflexly

Apomorphine is alone used of the drugs of the former class It has two great advantages over all other emetics, that it can be given hypodermically and that it acts *quickly* It should be used in full hypodermic dose of one-tenth of a grain or more if the patient is of big size It is best *carried* in tablet form as the official hypodermic injection does not keep Vomiting should *occur* in a few minutes After vomiting the patient tends to sleep, for apomorphine is distinctly narcotic as well as emetic In some poisonings this last action is by no means beneficial, but even in morphine poisoning it is customary to use this drug, though there is always a question whether the apomorphine is going to do its own work or to aid and abet its sister drug Of the other class of emetics, mustard (a dessertspoonful in a pint of water) is active, and has the advantage of being a household remedy Zinc sulphate is the most efficient of the purely pharmacopœial drugs, its dose of half a drachm may be exceeded, but if this is *done, one* is bound to continue its administration till vomiting *does occur* Copper sulphate is good, but is more likely to leave traces of irritation than is zinc sulphate, Antimony (in the form of tartar emetic) and ipecacuanha act too slowly to be satisfactory emetics The latter is safer and may be *at* hand, in *the* form of ipec wine, as a household remedy, if so the full emetic dose, according to age, should be given, followed by teaspoonful doses at intervals of ten minutes till vomiting occurs, but in poisoning cases such slow action is dangerous Common salt in strong solution, as strong as the water will dissolve it, may fail, but the use of this, combined with tickling of the throat, needs as little special apparatus and material as does any method of causing vomiting

The addition of suitable purgatives to emetics given is not to be forgotten These prevent absorption, especially where some antidote is being used which causes a temporary precipitation of the poison.

Gaseous poisons have to be eliminated by the respiratory tract and the elimination is best procured by the use of oxygen, this should be given, not by the haphazard method of holding a tube near the face, but with a mask such as is used for gas administration

A mixture of 95 per cent of oxygen and 5 per cent of carbon dioxide acts best, for the carbon dioxide in this excess stimulates the respiratory centre to act more vigorously In coal-gas poisoning carbon monoxide fixes itself to the hæmoglobin of the red blood corpuscles and is difficult to displace In poisoning by prussic acid an even more difficult problem arises, for this inactivates all the tissues it meets, so that the *transmission of oxygen becomes* very difficult

The introduction of poisons *hypodermically* takes away any chance of elimination by emetics or stomach-tube and throws all the stress of treatment on neutralisation in the tissues or on elimination by the natural channels, and on support of the patient till the poison wears itself out

Neutralisation of the Poison

A knowledge of pharmacology here becomes essential Many poisons fall into classes and can be treated accordingly, others need individual consideration

We have no antidote which counteracts all poisons, but both fatty and albuminous material form a layer on the walls of the digestive tract, protecting them, and actually attach themselves to many poisons of the corrosive and irritant type White of egg, milk, oils, and linseed tea are valuable in this class Chalk, lime, magnesia and water in which soap is suspended, act by neutralising acids and precipitating insoluble salts of the earthy metals Charcoal delays the action of many poisons both alkaloidal and irritant

Many of the above-mentioned antidotes are to be found in the home and none are likely to do harm, unless it be *oils in the case of phosphorus* poisoning

Alkaloids —Death in most poisons of the alkaloidal type is due to paralysis of the respiratory centre, and drugs which sustain this centre, such as caffeine and strychnine, are largely used

Tea and coffee may be given, if necessary by rectum Apart from their stimulant action, the tannin in them, when given by the stomach, acts as a true antidote, for it precipitates alkaloids Tannic acid may also be given in pure form or in one of its vegetable combinations It is obvious that the precipitated alkaloid must be hurried out of the intestine, it is only precipitated, not destroyed Potassium permanganate is given in weak solution, because it oxidises alkaloids and destroys them A weak solution of this is often used to wash out the stomach, especially in opium poisoning

Strong alkalies are neutralised by weak acids such as vinegar; strong acids by weak alkalies such as carbonates and magnesium oxide Irritant poisons are held up by albuminous and fatty material

Some Individual Poisons

Carbolic acid and its relatives, all of which are narcotic as well as corrosive, easily hold the *first* place for frequency, and so for importance Sulphates, best given in the form of magnesium sulphate, render inert all the carbolic acid with which they come in contact, whether in the *alimentary* tract or in the body tissues Till the *sulphates in the body* are overcome, the carbolic group cannot act on the tissues

Oxalic acid needs not only neutralisation but neutralisation with some salt which throws down *insoluble oxalate*

Calcium salts in the form of chalk and lime water are satisfactory, but potassium and sodium are to be avoided

Morphine poisoning is now rare. Artificial respiration should be tried where breathing fails, but it is probable that the very active exercise that is sometimes practised, especially when combined with exposure tends to exhaust the patient and to spread the poison

Strychnine Poisoning.—Here the hope of recovery depends on the stomach being emptied before the spasms become severe, and early injection of apomorphine and early washing out of the stomach mean much. The use of chloroform anæsthesia to allay spasm is justified though it is not without risk. Even if unsuccessful in saving life it does allay the mental anguish which is one of the features of this poisoning

Belladonna may to some extent be met by pilocarpine injection, but pilocarpine may weaken the heart and the dose must not be large Fortunately belladonna cases usually do well.

Phosphorus poisoning has largely disappeared with more stringent regulations as to the use of white phosphorus in matches. Oils are here to be avoided Oxidising agents as weak liquor hydrogen peroxidi or sanitas may be given. Copper sulphate is a suitable emetic, for copper is precipitated in metallic form on the particles of phosphorus and renders them inert. Three grains may be given every five minutes till vomiting occurs

Arsenic poisoning is usually met by an attempt to precipitate the poison as an insoluble arsenite This is said to be brought down when ferric hydroxide is given. A drachm of tinctura ferri perchloridi in half an ounce of water is mixed, on the spot, with half a drachm of bicarbonate of soda dissolved in half an ounce of water and the mixture, which contains a bulky precipitate of ferric hydroxide, is swallowed The same dose is taken several times at intervals of five or ten minutes.

General Treatment

It is too often forgotten that the patient himself must be carefully looked after; this may occur in the private house as well as in the accident room of an institution. If the sufferer is doomed we must at least make him comfortable, and, even if his fate hangs in the balance a dose of morphia may help by lessening shock Too frequently one sees a patient left in a cold collapsed condition, a condition probably accentuated by water dashed over him for stimulant purposes or spilled when the stomach has been washed out Warmth is essential if the patient is to be brought round Hot blankets and rectal injections of hot fluids help to ward off collapse.

Preparations for Emergencies

Every doctor in practice should have ready for emergency a stomach-tube with funnel. glycerine, gag, hypodermic syringe, morphine and apomorphine in tablets, zinc suphate, magnesium sulphate, charcoal, potassium permanganate, iron perchloride, and sodium bicarbonate. Any case of poisoning may be more serious than it appears at first sight. Treat it early and actively, and do not send it to anyone else, unless he is very easily reached or has apparatus more efficient than you have. Time means life.

(2) Chronic Poisoning.

Of this little need be said, for in most cases to recognise the cause is itself to stop the trouble Such cases arise. (1) in certain trades—here the practitioner is more likely to have to give evidence than to treat; (2) in drug habits, morphine, veronal, alcohol—here the treatment is special and is fully noted in special and general medical literature; (3) in casual poisonings as from arsenic in wall-papers and from lead in water-supplies; (4) as a result of foul play. In some cases elimination may be helped. Lead, for instance forms with iodides a soluble salt and for this reason iodides are given to get it out of the tissues With sulphates it forms the very insoluble lead sulphate; for this reason magnesium sulphate is given to precipitate the excreted or unabsorbed salts in the intestine and to help to carry them out of the body.

MEDICAL RESEARCH COUNCIL.

ANNUAL REPORT FOR 1925-26

The report[1] of the Committee of the Privy Council for Medical Research for the year 1925-1926 records a change in its composition, the office of Chief Secretary for Ireland having become obsolete The Committee now consists of the Lord President of the Council, the Secretary of State for Home Affairs, the Secretary of State for Dominion Affairs the Secretary of State for the Colonies, the Minister of Health (England and Wales), and the Secretary (now Secretary of State) for Scotland. The Secretary of State for Home Affairs, while representing the interests of Northern Ireland is representative also of the interests of industrial hygiene in their relation to medical research.

The grant-in-aid of £135,000 provided by Parliament for the expenditure of the Medical Research Council during the financial year has been allocated as follows · For administration, £8500: for the expenses of the National Institute for Medical Research at Hampstead and of the farm laboratories at Mill Hill, £45,500; for research grants to scientific workers and for the expenses of their researches at other centres, £81,000. The number of members of the Medical Research Council has been increased from ten to eleven and now includes: the Earl of Balfour (chairman) Lord Mildmay of Flete (treasurer) Mr. William Graham M P, Sir Frederick W Andrewes, Prof. E P. Cathcart, Prof G. Dreyer, Sir Archibald E Garrod, Sir Frederick G Hopkins, Professor C. J Martin, Sir Charles S Sherrington, Sir Cuthbert S Wallace and Sir Walter M. Fletcher (Secretary)

In the introduction to this year's report the Council give some admirable examples of the interplay between what sometimes seems to be only the academic work of the scientific laboratory on the one hand and, on the other, the work of applied or practical medical science These examples serve to illustrate the kind of work being done under their auspices, which is described in more detail later in the report

Histamine

The isolation of histamine from ergot and then from the wall of the human intestine by Dr. H. H Dale, Prof. G. Barger and Dr. P P Laidlaw some years ago has proved to be of great physiological significance Its bearing on our knowledge of the mechanism of shock and of the capillary circulation in general is familiar to our readers as are also the researches by Sir Thomas Lewis and his colleagues, which show that the reaction of the skin to certain insults produces effects of local flushing and swelling indistinguishable from those produced by histamine[2] At many other points the production of histamine in the body seems to take on a wide medical significance Its identification in the liver has a bearing upon some recent claims made in Canada for an extract of liver which was believed to have specific properties of lowering the blood pressure in man

Examination of such an extract by Dr. C H. Best and Dr Dale showed the presence in it of two vasodilator principles, which were subsequently identified with choline and histamine respectively Physiological experiments with an extract prepared from lung under similar *conditions* showed that it was peculiarly rich in substances lowering the blood-pressure having an action mostly of the histamine type. Mr W V Thorpe was able to isolate from a purified lung extract about three-quarters of the active principle present according to the physiological estimate and to identify it chemically as histamine obtaining from 10 kg.

---

[1] Report of the Medical Research Council for the year 1925-26 London H M. Stationery Office Pp 161. 3s 6d

[2] See The Lancet, Jan 1st, 1927, p 39

of fresh lung a yield of nearly 300 mg of this intensely active base Extracts of other tissues are now being studied by similar methods It is already clear that a widely spread vasodilator substance, long known to be yielded by almost all tissues of the body, will probably prove to be histamine

Clinical investigations are being made by Miss I Harmer, working under Sir Thomas Lewis, on the action of liver extracts and of artificial mixtures of choline and histamine on patients with high blood pressures.

Cholesterol and Vitamins

The most familiar of the sterols is cholesterol, which occurs in gall-stones, in the natural grease of the skin, in the sheaths of nerve-fibres, and is widely distributed elsewhere in the animal body. What was known as the result of long and laborious investigations, of its origin and fate in the body, suggested that it was a relatively inert substance Meanwhile chemical studies of great ingenuity and elegance had revealed the complex architecture of the cholesterol molecule, and its relation to that of other sterols occurring in animals and plants The recent discovery that the antirachitic vitamin D is actually formed when cholesterol and certain other sterols are exposed to rays of ultra-violet light considered in relation to the structure of the sterol group will, it is hoped, lead to an understanding of the relation between the effects of natural foods and of substances like cod-liver oil, and those of exposure to clear sunlight in clean air, in producing normal and healthy development of the body The Council acknowledge the help given to Mr O Rosenheim and Mr Webster in their work by Prof Windaus of Gottingen and Prof I M Heilbron of Liverpool

Insulin

The Council draw attention to their prophecy in their annual report for 1922-23 that "insulin will prove to have an importance for physiology far beyond that of its use in the treatment of diabetes" This prophecy has received ample fulfilment

Dr Best and Dr J Hoet of Louvain have been working in collaboration with Dr Dale and his colleagues at Hampstead, and joint investigations have been undertaken into the fate of the glucose which disappears from the circulation under the action of insulin The conclusion provisionally arrived at is that insulin not only promotes the storage of circulating glucose as glycogen, but has a restraining influence on the new formation of carbo-hydrate in the liver On this conception, therefore, the action of insulin in excessive doses is merely an exaggeration of that which it exerts in physiological and therapeutic amounts As an incidental outcome of this work on insulin, phenomena have been observed by Dr Hoet and Mr H P Marks which have an important bearing on the nature of *rigor mortis*, and by implication, therefore, on the chemical changes which result in muscular contraction Workers with insulin have often observed that an animal dying from an overdose becomes rigid with remarkable rapidity Dr Hoet and Mr Marks found that the same precipitate onset of *rigor mortis* occurred in rabbits which died after daily administration of thyroid substance for some weeks The common factor was the practically complete exhaustion of the muscle-glycogen, and the consequent failure to rebuild the hexosephosphate or "lactacidogen"

They found that such glycogen-free muscles enter into rigor with their reaction still alkaline—an observation already made, indeed, by Claude Bernard in 1879, but apparently overlooked in the recent development of theories of contraction and rigor

The new evidence strongly suggests that the disappearance and reformation of lactacidogen are factors as important, in contraction and relaxation respectively, as are the appearance and removal of lactic acid , and, further, that *rigor mortis* is essentially a contraction rendered irreversible by failure to reform the lactacidogen, either through shortage of the raw material, when glycogen is exhausted, or through death of the synthetic mechanism, as in ordinary *rigor mortis*

Diet and Teeth

Some eight years ago Mrs May Mellanby showed that deficiency of the vitamin now labelled D in diet otherwise complete and abundant, if inflicted during the period of dentition, leads, in animals, to the imperfect development of the jaws and teeth, this deficiency, according to the degree of its severity, causes interference with the formation of the enamel coating of the teeth, ranging from complete absence of enamel through various grades of imperfection, more or less notable, of the fine prismatic architecture of the enamel upon which its great hardness depends The deficiency in diet leads also to corresponding malformation of the dentine of the teeth

When these results were first reported, doubt immediately arose as to whether the results of these animal experiments could be related directly to the observed phenomena in human beings The general experience of dentists led them to believe that dental decay, even if more common in badly formed teeth, is common also in teeth apparently perfect in their enamel It led them further to believe that decay can hardly be related directly to the diet (irrespective of the possible external effects of food retained within the mouth) since decay had seemed to be as common in the teeth of the well-to-do classes, and among individuals obviously well nourished from birth, as in those of the poorer classes or among persons bearing other marks of faulty nutrition Mrs Mellanby proceeded accordingly to make further inquiry She found in the first place that ordinary naked-eye examination of the teeth is not enough to show faults of fine structure Microscopic examination of over a thousand shed or extracted teeth from children of all classes revealed wide spread defects in structure both in enamel and dentine Of the badly-formed teeth 95 per cent showed decay , of the well-formed teeth only 23 per cent showed decay In the defective teeth in which no caries was present good secondary dentine was in general found The teeth of normal structure that showed caries had usually badly-formed secondary dentine The explanation of these exceptional cases is probably provided by the results of animal experiments, which have shown that good secondary dentine is formed in the teeth upon an adequate "calcifying" diet, even though the original enamel had been badly formed as the result of inadequate diet during the time of dentition With Dr Lee Pattison, Mrs Mellanby has already investigated the actual results of varying the amounts of calcifying potencies of the standard diets in a large community of children. Clear indications have already been given that the amount of new caries is greatly diminished by the addition of the vitamin When, on the other hand, the vitamin is diminished and the anti-calcifying substance found in cereals, especially in oatmeal, is increased, caries spreads rapidly The Dental Committee who supervise the programme of work which the Council undertake with large assistance by grants from the Dental Board of the United Kingdom, are now making more extended inquiries in these directions

The paradox that persons apparently completely nourished throughout life may have teeth of which the architecture nevertheless shows signs characteristic of a specific deficiency in diet, has great biological interest It may be solved if we may suppose what only further research can prove—namely, that in a body rapidly growing under the stimulus of full nutrition, the calls upon the available vitamin made by particular parts of it may be so insistent or for some reason so successful that other parts, as for instance, the teeth, fail to gain their due supply, and a relative local deficiency is established

In the light of these recent studies it seems possible that the teeth of a nation may give a sensitive index of the degree to which the constitution of the diet is adapted to the complex needs of each section of the population

Filter Passers and Cancer

Fifteen years ago Dr Peyton Rous showed that filter-passing material obtained from chicken sarcoma could propagate, without the presence in it of any visible cells, another malignant and rapidly fatal tumour of the same kind in a bird of the same breed

It will be remembered that in 1925, Dr W E Gye, working with Mr J E Barnard, found evidence which he believed could only be explained on the hypothesis that the filtered and cell-free material obtainable from the Rous tumour is separable into two factors, either of which alone is innocuous and inactive One agent he believed to be a non-living chemical substance, the so-called "specific factor," which is rapidly destructible at a temperature of 55° C and bears the specific racial qualities of the particular animal from which it is immediately derived The second factor he regards as a corpuscular virus, small enough to pass through very fine filters, too small to be visible by ordinary microscopic means but not too small to be acted upon by gravity in a fluid suspension, and not too small to be photographed if light rays of wave-lengths beyond the visible spectrum be used with appropriate apparatus. The specific chemical factor, inactive alone, can be activated by the addition to it of the virus; the activating virus is not racially specific because a virus derived from a malignant tumour in one kind of animal can be substituted for the virus of another. Thus Dr. Gye has repeatedly produced tumours in the fowl by taking the specific factor—that is, an extract of fowl tumour in which he believes the virus to have been destroyed, and by adding to it extract or "virus," derived from mammalian tumours, including cancerous and other growths removed from human patients by operation.

This hypothesis of the double nature of the effective agency allows at once the reconciliation, as the Council pointed out last year, of the two opposite schools of thought, namely—those who believe in some common causative factor of a parasitic kind as accounting for the points of similarity in the malignant tumours of all kinds of animals and those again who, knowing the impossibility of transmitting a malignant growth directly from one animal to another of different kind are disposed on this negative ground to resist as inconceivable any infective or parasitic theory of cancer.

Workers from the chief centres of cancer research of many countries have visited the National Institute during the past year for personal observation of Dr Gye's methods and results, with those of Mr Barnard. Time will show whether Dr Gye's provisional interpretation of his experimental facts is true in part or in whole but however that may be, it is certain that his work has brought fresh outlook and hope and has given a strong stimulus to new activities in the cancer research laboratories of almost every country.

On questions of fact some laboratories have confirmed, while some have hitherto not confirmed, this or that part of his work. It must be remembered that the technical manipulations involved are difficult and that their due performance must always largely depend upon individual skill. The chief issues raised are relatively simple and come from two sides.

From the beginning it has been doubted by some whether the chloroform with which Dr Gye treated the tumour extract does, in the concentrations used, effectively destroy the virus and leave the specific factor, as he believed, in isolation impotent to cause new tumour formation without the addition to it of fresh virus. In more recent work, already published in part, Dr Gye has found that other antiseptics of diverse chemical nature, like acriflavine or cyanides, can be used instead of chloroform. The chemical destruction of the virus by antiseptics finds closely parallel and confirmatory results in those of physical removal, as when the corpuscular particles of virus are separated mechanically, by very rapid spinning in a centrifuge, from the specific factor which remains in solution. Dr Gye is actively continuing this work and has found no reason at all to modify his position. His results in detail are being published as early as possible.

The second line of attack disputes the validity of Dr. Gye's claim that he can cultivate the virus outside the body by successive transplantations from tube to tube of culture medium. For it has been alleged in some laboratories that the tumour juice, which has been treated by antiseptics for the destruction of the virus and which is believed therefore to contain the "specific factor" alone, can be reactivated not only by "virus" from another tumour, as Dr Gye finds, but equally well by non-cancerous material, for instance by normal embryonic tissue. If that be true, then Dr Gye's hypothesis, though not upset, becomes widened almost to absurdity, because the virus becomes an agent of almost ubiquitous origin instead of one associated always with malignant growth. Moreover, since all Dr Gye's cultures contained embryonic tissue, his evidence for artificial cultivation of the virus outside the body is destroyed. Here is a conflict of testimony, of which only time can settle the outcome. The position will be clearer when the results of further experiments have been published for proper consideration.

It must be recalled, finally, that the problem which here challenges the scientific world is the proved and admitted capacity of the liquid juice of a tumour, free from any cells and containing no particles visible by ordinary light to carry within it two biological properties at the same time; one that of producing a new tumour, the second that of holding within itself some intimate pattern of substance which forbids propagation of the tumour except in an animal of the same species and of close blood-relationship within the species. In what part or parts of the fluid do these two properties reside? This challenge has been standing open now for 15 years. Dr Gye, in taking it up, has produced the first coherent explanation based upon experiment. Whatever be the final outcome of his work it has at least drawn many other workers already to face this outstanding problem which has been left disregarded too long.

(To be concluded.)

MEDICINE AND THE LAW.

Seditious Conspiracies

A MESSAGE from a Monmouthshire correspondent in the *Times* of Feb 14th mentions an alleged Communist plan for raising in South Wales a Workers' Defence Force with a medical branch and with personnel trained in the rendering of first aid. If there is at any time to be civil war, it is an admirable proposal that preliminary arrangements should be concerted for binding up the broken heads; but it is doubtful whether the non-combatant nature of a doctor's duties would protect him from the clutches of the criminal law if he joined a movement of this nature. Apart from the solemn capital offence of high treason, and apart from Acts of Parliament which deal with unlawful societies and seditious meetings, there is an Unlawful Drilling Act of 1819 which definitely prohibits "as dangerous to the peace and security of His Majesty's liege subjects and of his government" any meeting or assembly of persons for the purpose of training or drilling themselves or for the purpose of practising any military exercise movements, or evolutions without any lawful authority from His Majesty, a secretary of state, or an officer deputed to act in that connexion. Persons attending such meetings or taking part in such training are liable to a sentence of seven years' penal servitude. When, as during the stoppage of work in the coalfields last year, the Emergency Powers Act machinery has been brought into operation, the usual code of Emergency Regulations provides a summary method of dealing with the same range of offences, trial being thus expedited and simplified and punishment reduced. It is probable that, if it ever were necessary to institute large-scale criminal proceedings against persons concerned in anti-governmental movements—movements, that is to say, not directed against the particular government of the day, but against the general established order of government in the country—those persons would be indicted on a charge of seditious conspiracy. Such a charge flings its net very wide, and evidence of all kinds of acts and incidents becomes admissible as evidence of the common unlawful purpose. A seditious intention is defined in the legal text-books as possibly including five varieties—first the intention to bring into hatred or contempt, or to excite disaffection against, the king or the government and constitution of the country or against Parliament or the administration of justice; secondly the intention to excite His Majesty's subjects to attempt, otherwise than by unlawful means, the alteration of any matter in church or State by law established; thirdly, to incite anyone to commit any crime in disturbance of the peace; fourthly, to raise discontent or disaffection among His Majesty's subjects; and fifthly, to promote feelings of ill-will and hostility between different classes of such subjects. Those five alternatives are declared seditious on the high authority of Lord Halsbury's "Laws of England"; the language may sometimes sound old-fashioned, but the State would not be powerless in the face of serious threats Medical personnel might not be regarded as being trained or exercised in military movements and evolutions, but anyone who accepted membership of a seditious body and conformed to its orders, organisation, and operations would undoubtedly be taking part in a seditious conspiracy, even though the purity of humanitarian motives might offer some prospect of escaping the heaviest sentence. This discussion, it may be confidently hoped, is of academic interest only It is unnecessary to add that, the stronger and more elaborately organised an unconstitutional movement becomes, the greater severity is to be expected in the administration of the law

Professional Discipline An Imperfect Parallel

Those who are interested in statutory provisions for enforcing professional discipline will have noted the appearance of the new Solicitors Bill The Law Society has found that the statutory machinery for striking a solicitor off the Rolls or for suspending him temporarily from practice can be stultified because the person concerned can still obtain employment in a nominally subordinate position The Bill, therefore, proposes that no solicitor shall, without the written permission of the Society, employ or remunerate any person who, to the knowledge of the solicitor, has been struck off the Rolls or is suspended from practice Any solicitor dissatisfied by a decision of the Society in this connexion is to have a right of appeal to the Master of the Rolls The second clause of the Bill imposes a penalty upon anyone who has been struck off the Rolls or suspended from practice and seeks or accepts employment by a solicitor without disclosing his disability

These proposals show once more how imperfect is the superficial parallel between the disciplinary systems of the medical and the legal professions The Law Society is equipped with far greater powers over solicitors than the General Medical Council possesses over doctors Up to a point there is similarity Each profession is allowed to define its own standards of conduct and to apply them judicially Thereafter there is a marked divergence The solicitor who violates the accepted standards can at present be substantially—and, if the new Bill passes, may in future be absolutely—debarred from practising his profession in any form But the doctor who in similar circumstances is punished by having his name removed from the Medical Register is still left at liberty to practise medicine with but few restrictions Indeed, in one sense he has a positive advantage, for he can thenceforward compete without the restraint of professional standards against registered medical practitioners who are more scrupulous in maintaining recognised traditions

IRELAND.

(From our own Correspondent.)

Charter Day Dinner of the Royal College of Surgeons

The Charter Day Dinner of the Royal College of Surgeons in Ireland was held on Feb 19th in the College Hall, the President, Mr Andrew Fullerton, in the chair. Special interest was taken in the dinner this year, as it is the first occasion for over 60 years that the College has chosen as president a surgeon who resides outside Dublin Mr Fullerton is professor of surgery in Queen's University, Belfast, and one of the surgeons of the Royal Victoria Hospital, Belfast On only one previous occasion has the College had a president from the provinces—namely, in 1862, when Thomas Lewis Mackesy, of Waterford, was elected There was a very large attendance of Dublin Fellows and their friends to welcome Mr Fullerton, and no less than 30 of his colleagues from Belfast attended as guests In fact, the entire staffs of the Royal Victoria Hospital and of the Mater Infirmorum travelled to Dublin for the occasion Mr T. Healey, the Governor-General of the Irish Free State, was the principal guest Acknowledging the toast of his health, he said that the College had received its Charter in 1784, and now after a lapse of nearly 150 years, had gone to Belfast for its president The English College of Surgeons, which received its Charter in 1800, had last year gone to Leeds for its president, and there had selected an Irishman, who was also a Fellow of the Irish College In Irish medicine and surgery there was, he believed, no north and south; latitude and longitude were abolished He hoped that in the President's year of office this benevolent union between North and South would tend to dissipate prejudice in the interest of their native land Mr T E Gordon, Vice-President of the College, proposed the toast of Prosperity to Ireland No doubt, he said, the medical profession had great difficulties at the present time, but it had the advantage, which many had not, of a united Ireland For their boundary as a scientific body they must look to the limit of civilisation Among other speakers were Mr R W Livingstone, Vice-Chancellor of the Queen's University, Dr D Coffey, President of University College, Dublin, Sir Thomas Myles, Sir Arthur Chance M. Blanche, Consul-General of France, and Dr Bethel Solomons, Vice-President of the Royal College of Physicians of Ireland

PARIS

(From our own Correspondents)

Substitute Flour in Bread

In November last the Académie de Médecine went into the question of using substitute ingredients in bread-making. A special commission was appointed and has now reported that the use of such flours as those prepared from rice, maize, and manioc has drawbacks which are not counterbalanced by any economy; it should therefore be given up Naturally this report has evoked protest from colonial importers, in spite of which the Académie has adopted the following resolutions The addition of regular substitutes is without danger to the public health, but substitute flours alter the quality of bread if they are used in a proportion of more than 5 per cent In order to maintain a high standard of quality and economical production it is desirable that the supply of flour for bread-making should be regulated over a period of, say, five years During this time the extraction of flour from wheat should be fixed at as high a level as possible, and it may be necessary to arrange a scientific investigation of the methods adopted by the millers At least 10 per cent of rye-flour should everywhere be compulsorily added to wheat-flour Where local conditions make it desirable sarrazin-flour (buckwheat) may be substituted for rye, but all the unsuitable flours, such as rice, manioc, and maize, should not be employed

Protection of Infants against Tuberculosis

During the last three years Weill-Halle and Turpin, of Paris, have been attempting premunisation of infants against tuberculosis by injections of B C G vaccine This vaccine consists of an attenuated culture of tubercle bacilli, and, as recommended by Calmette and Guérin, is usually given by mouth a few days after birth In the present series of cases the children all belonged to infected families and had not had the benefit of this early protection, and the following method was accordingly adopted After it had been ascertained that the child was not infected a single subcutaneous injection was given, varying in quantity from a quarter to one milligramme The effects of this injection were very mild A local reaction occurred about the third week, ending in a small cold abscess which later drained itself and healed spontaneously The tuberculin skin reaction became positive in two or three months It may be concluded from these first attempts that this new method is harmless; it remains to be seen what is the minimal efficient dose and what are the relative advantages of ingestion and injection.

The Sick should be Fed.

An original communication has recently been made to the Société de Thérapeutique by G. Leven, of Paris, who considers that the first duty of a doctor should be the nourishment of his patient. In dealing with disease, whether acute or chronic, the rôle of food is infinitely more important than that of drugs. Often starvation causes symptoms which are wrongly imputed to the malady; it makes illness worse and complicates or prolongs the time of convalescence. In some cases—for example, gastric ulcer or the vomiting of acidosis—it is customary to stop all feeding by the mouth. Leven, however, considers that it should be continued, for it has from every point of view a beneficent influence, and is much more satisfactory than nourishment by the rectum, which has many, and often serious, inconveniences.

Habit in Disease.

Charles Fiessinger, of Paris, points out that habit is important in the manifestations of disease, just as it is important in mental processes. The picture of the illness remains after its real cause has gone away. Sometimes a permanent slow pulse, which has had its origin in an acute attack, or again, an albuminuria following infectious nephritis, will clear up as if by magic when confidence is restored to the patient. In all chronic disease custom plays its part, and after the turn of the illness it is difficult to get rid of it. An emotional shock, such as can be produced by a doctor's emphatic pronouncements, may sometimes work the miracle, and sudden improvement may occur in face of apparently formidable disease.

Regulation of the Production and Sale of Vaccines.

Nowadays there are many and various kinds of microbic vaccines, and it is astonishing that so many remedies should be put on sale without restriction either as to distribution or mode of employment. The only real guarantee which exists in France is that the laboratories which prepare them must have secured a special licence. In a recent paper read before the Académie de Médecine G. Petit pleads for rigorous control, laying down rules and regulations which should govern the bacteriological and physiological analyses of vaccines, to make certain that they have been properly prepared, and that they are efficient and harmless.

Increase of Medical Students.

It might be supposed that as medical study takes longer and costs more than formerly, the number of students would be diminishing. But it is not. In 1922 the preliminary scientific certificate which every student must take before starting medicine was granted to 1349 students throughout France; in 1925 the number had risen to 1900, and last year to 2211.

Dr. Léonce-Pierre Manouvrier, who died recently, was director of the Laboratory of Anthropology and of the Physiological Department of the Collége de France. He was a member of many learned societies abroad and wrote about 150 original memoirs on anthropology, zoology, physiology, psychology, and criminology. He was born on June 28th, 1850, at Guéret (Creuse), and qualified as a doctor of medicine.

The Chamber of Deputies has passed a Bill extending to physicians, surgeons, and hospital personnel the right of compensation for accidents sustained whilst on duty.

Courses in dermatology and venereology have been arranged by Prof. M. Jeanselme at the Hôpital St. Louis, Paris, in April, May, June, and July. Particulars may be had from Dr. Burnier at the hospital.

From March 28th to April 8th there will be a vacation course at the Hôtel Dieu under the direction of Prof. M. Villaret. The subject is Modern Conceptions of Clinical Practice and the Diagnostic Use of Current Laboratory Methods.

"Audi alteram partem."

POST-GRADUATE TOUR FOR SURGEONS

To the Editor of THE LANCET.

SIR,—May I through the medium of your columns call the attention of the surgical profession to the proposed post-graduate tour in the United States of America and in Canada which is now being organised by the Surgical Section of the Royal Society of Medicine. It is proposed that the complete tour should last six weeks and the itinerary has already been set forth in your issue of Feb. 12th (p. 368). It has, however, been found necessary to alter the date of departure which has now been fixed for August 20th. This alteration has been made partly to avoid interfering with the end of the meeting of the British Medical Association and also for the reason that more American surgeons of eminence will, by that time, have returned from their holidays.

By arrangement with the Cunard Company the cost of the whole tour, including ocean passage, rail and other transport and hotel expenses, will be approximately £140. Travelling facilities on the same terms will be offered to wives of those taking part in the tour. Membership of the tour is open to all members of the Section of Surgery and to all Fellows of the Royal Society of Medicine on nomination by the Organising Committee. Non-fellows who wish to join must be nominated by two members of the section and be approved by the Committee.

The tour has been arranged to give surgeons in this country an opportunity of seeing the work of some of the important surgical clinics in the United States and Canada at a reasonable cost and with the expenditure of the minimum of time and personal trouble. Should the numbers exceed 100 a special train for the party will be provided and the Cunard Company will send a travelling courier. It is important that the names of those wishing to join should be in the hands of Mr. C. Max Page, the honorary secretary, 134, Harley-street, London, W. 1, at an early date as final reservations will have to be made shortly on account of the large number of Americans returning home at the time of the proposed tour. The organisers hope that this invitation will meet with an adequate response and that the members of the tour will comprise a representative body of British surgeons.

I am, Sir, yours faithfully,

V. WARREN LOW,
President of the Section of Surgery of the
Royal Society of Medicine.

Harley-street, W., Feb. 19th, 1927.

ACUTE POLIOMYELITIS

To the Editor of THE LANCET.

SIR,—The admirable papers of Dr. James Collier and Dr. F. M. R. Walshe in THE LANCET of Feb. 12th will undoubtedly be of great assistance in the clinical diagnosis of acute poliomyelitis.

The authors apparently are wedded to the idea that the disease is invariably transmitted from human being to human being, generally indirectly through a human carrier. I was glad to note that in the discussion (p. 340) on Dr. Walshe's paper, Dr. M. H. Raven (himself a patient who had recovered from the disease) stated that from his observations and experience he could not consent to the idea that dirt and flies could be left out of the question of the agencies of spread.

In the year 1911, several cases of poliomyelitis occurred in Norfolk, for the most part isolated cases, except that in the rural district of Downham three small groups of cases occurred. In the autumn of 1926 some eight cases have occurred in Norfolk widely separated from one another. There can be no question that there is undoubted evidence of spread in many instances in institutions by human agency, but in many rural areas isolated cases of poliomyelitis occur, and one has to search for other agencies of infection · even in the multiple instances in institutions there is no evidence that enquiry was made into a possible insect carrier of infection In a presidential address to the Eastern Counties branch of the Society of Medical Officers of Health, published in *Public Health* (December, 1914), I reviewed the possible sources of origin Generally speaking, poliomyelitis is a *rural* disease, single cases occurring in widely separated and sparsely populated districts, without any evidence or indeed possibility of contact even with a human carrier contact of a known case The very fact that, except in epidemic form, the disease is distinctly a *rural* disease makes it necessary to look for other than human agencies In this connection one should look for evidence of strange illness among the lower animals, and to a biting insect which might carry infection from a diseased animal to a human being. It is possible even for a biting insect to carry the germ from a saprophytic source direct to a human being

The first question to be answered is Why under normal conditions is sporadic poliomyelitis more a rural than an urban disease? In every case of poliomyelitis which I have investigated I have made special observations as to the evidence of any biting insect and have in every instance found evidence of existence in the neighbourhood of the biting stable fly — *Stomoxys calcitrans* I find that Rosenau, of New York, has this fly under suspicion The second question to be answered is · Why does the disease generally attack young children? The third question is Why is the disease generally seasonal, being limited, as a rule, to late autumn and summer?

An answer to the second question—bearing in mind the generally infrequent and sporadic nature of the disease—is that during the warmer months children are generally clad in shorts, leaving their bare legs and arms more assailable to the bites of insects An answer to the third question is that all insects breed most numerously in the warmer months The stomoxys breeds in warm stables and cowsheds—breeds longer than the domestic housefly and, owing to its warmer environment, resists mild frost better Moreover, being a biting fly receiving its nourishment from the blood of living animals, it spends a large part of its existence in contact with warm-blooded animals, which is another reason why it may still be found in numbers in the late autumn when the *Musca domestica* has practically disappeared —the latter fly being very susceptible to cold In some of the cases I have investigated the mother has known that the child has been bitten by flies In some of the cases I have actually seen the marks of the bites In one case a cow had died of some mysterious disease in a cow-shed about 200 yards away, and there were many specimens of stomoxys in the home

One interesting batch of cases was recorded in THE LANCET (1913, ii, 1380) by Dr George Jubb as having occurred on the route of travel of a baker's cart Dr. Jubb thought children might have been bitten by vermin from the donkey which drew the cart Surely a more probable biting insect was the horse-fly or stable-fly which probably in numbers teased the unfortunate steaming animal in the course of his round and regaled themselves with an occasional meal from the legs and arms of the children in shorts in the various villages at which he stopped

Mr R C Elmslie, as an orthopædic surgeon, naturally has to deal with a large number of cases of poliomyelitis He states that a large number of these cases are not parts of epidemics but isolated cases Would not such cases be likely to be the occasional victims of a biting infected fly? Dr Raven reminded members of the Medical Society that macerated flies had been proved to be capable of infecting monkeys A little more detail of these experiments is required Anderson and Frost fairly definitely proved by experiments on monkeys that infection of poliomyelitis could be conveyed by stomoxys Mr P B Roth described in THE LANCET (1913, ii, 1378) an interesting small epidemic of six cases in five small villages, the only common factor to all being the proximity of stables and cattle yards A disease resembling poliomyelitis has been recorded as occurring among horses A horse or donkey trailing a tradesman's cart accompanied by pestering biting flies might easily carry an infected stomoxys from village to village and thus explain sporadic cases within a limited area, for many a human being including myself can personally testify to the vicious biting propensities of this fly

I am, Sir, yours faithfully,

J T. C NASH, M D, D P H,

County Medical Officer for Norfolk

The Shirehouse, Norwich, Feb 16th, 1927

OPHTHALMIC BENEFIT

To the Editor of THE LANCET

SIR,—You may remember that some months ago there was a considerable extension of what is known as "ophthalmic benefit" under the National Health Insurance Acts Previous to this the various "Approved Societies" assisting in the administration of the Act granted what was known as "optical benefit", this, in practice, meant that they were prepared to pay up to a certain amount for spectacles made by opticians, the question whether the glasses were prescribed by the optician concerned or by an ophthalmic surgeon being of no interest then to the Approved Societies

Recently the Ministry of Health has sanctioned the Approved Societies giving what is now termed "ophthalmic benefit," where the societies have funds available for the purpose Under this scheme the societies pay the ophthalmic surgeon a fee of one guinea for an examination of the insured person's eyes, the surgeon prescribing glasses if required, the prescription being taken to the optician and made up with the same proviso for part payment of the optician's charges as before I am informed that about a third of the Approved Societies have adopted this scheme of ophthalmic benefit, the remaining two-thirds still giving only optician's benefit

The modus operandi for the insured person to get this benefit is first to apply to his society for an ophthalmic benefit form, this he takes to his panel doctor who signs it, certifying either (1) that the services of an ophthalmic surgeon are essential, or (2) that he should go to an optician The patient sends the completed form to his society, who then issues a letter telling him to see an ophthalmic surgeon, and either gives him the name of a particular surgeon to be seen or gives him several of surgeons living in his neighbourhood The onus is thus on the panel doctor of deciding whether the services of an ophthalmic surgeon are necessary, or to put it bluntly, he is expected to see that cases of cataract, glaucoma, or new growth are not sent to opticians for treatment

I gather that the societies that do *not* give "ophthalmic benefit" but only pay for spectacles, take the view that in the majority of cases the services of an ophthalmic surgeon are unnecessary and that an optician can do all that is needful With this view I am inclined to agree The vast majority of eye patients require glasses only. When they consult opticians I would go so far as to say that the opticians in 80 per cent of cases prescribe correct glasses and give their patients satisfaction Probably 15 per cent of patients get glasses sufficiently good for the purpose, but which might be improved by an ophthalmic surgeon The balance of 5 per cent have some ocular disease, and my experience is that opticians generally refer these cases to hospitals In spite of a letter in your columns a few weeks back I think that the *real damage* that can be done to the eyes by unrestricted prescribing by opticians is extremely slight, practically the only risk being that a case of rise of tension in the eye from whatever cause might go undetected. Now, after all, glaucoma is not a very common disease and would probably be detected by the patient's panel doctor before he went to the optician.

These views may sound heretical to some, but I think that the majority of ophthalmic surgeons will agree with me as to their correctness For doing this ophthalmic work the Ministry of Health devoluted to the British Medical Association the privilege of compiling a list of ophthalmic surgeons who would be willing to examine National Health Insurance patients for a fee of one guinea Practically all the ophthalmic surgeons in England are on the list They are about 600 in number, of which about 100 are in the area of London and its surrounding suburbs

Why the Ministry of Health handed the formation of the list (now known as the " Ophthalmic Panel ") to the British Medical Association I do not know However much one approves of the Association—and I do thoroughly approve of its activities—one cannot help feeling that it was undesirable for the Government to hand over this function of forming an ophthalmic panel to what, after all, is a private organisation banded together for the mutual benefit of its members Human nature being what it is, non-members of the British Medical Association will always feel that members of that body will " have a pull " in getting on to the ophthalmic panel It would have been much better for the Ministry to have retained the formation of the ophthalmic panel in its own hands

Concerning the personnel of the ophthalmic panel, there are men on it who, some may say, have not sufficient experience and knowledge of eye work to justify their inclusion There is a real danger, especially at first, that if inexperienced men get on the ophthalmic panel it will bring it into contempt and disrepute My feeling is that no man should be on the ophthalmic panel unless he is on the staff of an eye hospital in a senior or junior capacity, or on the eye department of a general hospital or in charge of a school clinic There are men on the panel who have held junior eye appointments years ago, but now hold no post bringing them into touch with eye work These men are not good enough for the responsibility and they have no opportunity of keeping abreast with the times

The ophthalmic panel consists of a list of names and addresses of doctors and nothing more It is not on sale to the public, but the British Medical Association has supplied copies to all the Friendly Societies From this document the *officials* of the societies have no means of knowing anything about the position and status of the medical men *on it*, unless they refer to that excellent non-official publication the Medical Directory In fact, the list is about as much use *to the* ordinary man as that list of 4000 members that the Stock Exchange so kindly supplies one with if one wants the name and address of a good stockbroker I suggest that when the next list is published the ophthalmic appointments actually held at the present *time* by its members should be included something after the style of the Medical Directory A point to be considered is whether the list of names of members of the ophthalmic panel should be *available to the* public in the post offices as is the case of the ordinary panel Some of the leaders of our profession might consider it savour of undue advertising, others might think it excellent health propaganda.

It is a question in my own mind whether ophthalmic benefit would not be much better administered by some such scheme such as the following —

The patient interviews his panel doctor and requests a certificate to go to an optician This interview with his doctor would exclude cases of gross eye disease being untreated and should exclude cases of chronic glaucoma being missed The optician when he sends his bill to the *society* should give a certificate that the patient with the new glasses gets normal vision (6/6 Snellen with each eye, and Jaeger No 1 for reading, or whatever standard is agreed on) If the case does not get normal vision, the patient should be referred to an ophthalmic surgeon, with the proviso that any glasses prescribed should be made by the original optician

This scheme should satisfy the societies who now feel that many cases are sent unnecessarily to ophthalmic surgeons It should satisfy the opticians who know that they are inclined to lose cases if an interview with an ophthalmic surgeon is not properly safeguarded as above Lastly, and most important of all, the patient would feel that his eyesight was being properly looked after without his time being wasted with unnecessary interviews with ophthalmic surgeons

The point that it is wished to emphasise is that the man in general practice may not know much about the prescribing of spectacles (and the optician from long experience does this pretty well) But that does not mean to say that he (the practitioner) knows nothing about diseases of the eye One feels that he is not given enough credit for the amount of ophthalmic knowledge that he does possess

I am, Sir, yours faithfully,
ADRIAN CADDY, M D , F R C S

Upper Wimpole street, W

*** Mr Caddy's frank letter brings to our mind certain difficulties in connexion with any official recognition of the prescribing optician, and in other directions will invite different opinions from *those* which he has expressed The chief danger in the ophthalmic panel, that men not competent for the work may undertake it, is a fact, but there is a sub-*committee* in existence to decide whether or not a name is to be inserted on the panel, and this body is fully alive to the position —ED L

POST-OPERATIVE FACIAL PARALYSIS

To the Editor of THE LANCET

SIR,—On p 392 of to-day's issue I am reported as saying that the possibility of facial paralysis makes me hesitate before performing a labyrinthectomy. Labyrinthectomy is a serious operation; the risks to be considered are those involving the patient's life, and purely cosmetic considerations have no place among the indications for the operation I should never allow such a trivial complication to influence my decision that the labyrinth should be removed What I actually said was that the cases in which I had had to do a labyrinthectomy (as distinct from simply the radical mastoid operation) had provided my opportunities for observing the course of post-operative facial paralysis

I am, Sir, yours faithfully,
E WATSON-WILLIAMS

Clifton, Bristol, Feb 19th, 1927

THE BLOOD-GROUPS OF IDENTICAL TWINS

To the Editor of THE LANCET.

SIR —Dr G P Crowden's interesting analysis of the physical characters of a pair of identical twins in Guy's Hospital Reports raises another point of practical importance in addition to the question of their finger-prints already discussed *in* your columns I had always supposed on theoretical grounds that a pair of identical twins were likely *to* belong to the same blood-group, and that it should be possible always to use *one* of the pair with perfect safety as a blood donor for the other Dr Crowden's twins both belonged to Group IV (Moss) and so seemed to conform to the theoretical requirements I have recently however had the opportunity of putting this point to the test in practice with the opposite result Being called upon to treat by transfusion one of a pair of twins who was suffering from septicæmia, I naturally turned to his brother for the necessary blood I applied the usual test and found that the patient and donor belonged to Groups II and IV respectively I was thus able to use the healthy twin as donor, but a demonstration had been afforded that the blood even of identical twins cannot be regarded as interchangeable. The twins in question were undoubtedly to be regarded as "identical" in the usual acceptation of the term They resembled one another so closely that for many years they had been employed on the stage as an essential ingredient of certain well-known "mysteries"

I am, Sir, yours faithfully,

London, Feb 20th, 1927. GEOFFREY KEYNES

"SONNE" DYSENTERY IN GREAT BRITAIN.

To the Editor of THE LANCET

SIR,—The last two issues of THE LANCET have contained references to the occurrence of cases of dysentery in Great Britain. That of Feb 12th reports a note by Dr Robert Richards on "Some Cases of Dysentery in Aberdeen," including an interesting case that was operated upon for intussusception on account of a history of a tumour having been felt, and which turned out to be a case of dysentery In his paper Dr Richards states that the latest figures for Britain, for the supposed causal relationship between the dysentery bacillus of Flexner and infantile diarrhœa are my own, and that "I had found dysentery bacilli in 13 cases out of 150 treated in the Hospital for Sick Children, Great Ormond-street"

In THE LANCET of Feb 19th Dr F H A Clayton reports a case of Sonne dysentery in England, and he adds that the Sonne bacillus had not been met with in England until Dr Channon in 1925 obtained it from a man who had had dysentery in Egypt previously I should like to be permitted to make a few observations upon these two interesting papers, because I believe that dysentery is much more prevalent amongst the general population than is generally recognised

At the January meeting of the Pathological Society of Great Britain I read a paper on some observations I had made on the Sonne dysentery bacillus and the *B coli anaerogenes* As a result of investigations I have been carrying out over several years, I have come to the conclusion the organisms I isolated in 1921 from a considerable number of cases of epidemic diarrhœa and other forms of diarrhœa which occurred during that year, which in former publications I have called *B coli anaerogenes*, are really the same organisms as Sonne isolated from some of his cases of dysentery in Denmark Moreover, the organisms described by Dr J Bamforth in London, Dr. R Cruickshank in Glasgow, and others, as occurring in cases of ileocolitis and similar conditions are also the Sonne bacillus

With regard to my figures quoted by Dr Richards —namely, "13 cases in which dysentery bacillus was isolated out of 150 cases studied," may I point out that of those 150 cases only 107 were examined bacteriologically? To this number, however, must be added the 25 cases in which I isolated the *B coli anaerogenes*, and which must now be regarded as the Sonne type of dysentery, giving a total of 38 cases out of 107 (35 4 per cent) examined bacteriologically in which dysentery bacilli of one or other type were isolated

There are several other points I could refer to in connexion with the prevalence of dysentery in this country, but as I intend to write a paper upon this subject shortly I shall be content to leave the matter here for the present

I am, Sir, yours faithfully,

DAVID NABARRO

Harley-street, W, Feb 22nd, 1927.

THE CASE OF COLONEL KYNASTON

To the Editor of THE LANCET

SIR,—Your report of the withdrawal by the Public Prosecutor of the summons charging me with having "illegally, wilfully, and falsely used the descriptions M R C S Eng, and L R C P Lond" gives the impression that it was due to the quashing of my conviction under the Drug Act

This gives a totally false impression The summons was withdrawn after I had pointed out to the Public Prosecutor that the Royal Colleges had no statutory power to cancel their diplomas and that consequently their by-laws were of no legal effect

I am, Sir, yours faithfully,

JOHN KYNASTON, Lt-Col., M R C S Eng,
L R C P, Lond., late R A M C

Chepstow Villas, W, Feb 15th, 1927.

Obituary.

SIR JOHN UTTING, M R C S. ENG, L R C P EDIN.

SIR John Utting, who died last week, was a prominent figure in the corporate life of Liverpool At the age of 75 he was still active not only in the interest of the city's health, but also, and even more conspicuously, in the management of the city's finances Born in Norfolk, Dr. Utting qualified in London at the age of 22, and was at one time editor of *Guy's Hospital Gazette.* For three years he travelled abroad as a ship's surgeon and then, going to Liverpool, settled in a practice which before long became a large one At an early period he interested himself in public health, though it was not till 1899 that he gained a seat on the city council There he speedily made his mark, and for 20 years served as chairman of the port sanitary committee, as a memorial to his work there remains the large isolation hospital at Fazakerley His influence was largely felt in the coordination of the work of the university, the city analyst and the city bacteriologist, in so far as they bore upon public health matters, and the combined Public Health Institute at Liverpool is symbolical of the partnership which was eventually attained Perhaps, however, it was as a financial expert that Sir John Utting made his deepest impression upon the mind of the average citizen In 1919 he was made chairman of the finance committee of the corporation, and his budget speeches became famous for their clarity and the conviction they carried Under his regime corporation stock stood high A ready and forceful speaker, he was a master of the art of handling an audience, and deep convictions seemed to lie behind all that he said "His was a kindly nature," writes a colleague, "and in later years his fine presence and strong though friendly features made a picture hard to forget. Undoubtedly a great intellect has been lost and one of those sterling characters that are so ill to replace"

Sir John Utting leaves a widow, two sons and one daughter

JOHN FLETCHER PORTER, C B E, M B LOND
J P

ON Feb 17th Dr J F Porter died at Hackney at the age of 54 The son of the Rev J F Porter, he was born in Canada and educated at York, Leeds, and the London Hospital He qualified as L S A Lond in 1897, and in 1901 was appointed medical officer to the London County Council For many years he carried on a large general practice in the East End but he managed to combine this with a good deal of special work In 1913 he was appointed medical referee to the London Insurance Committee and later served the approved societies in the same capacity In the following year he became a member of the Special Medical Board on Functional Nervous Diseases and Epilepsy, and in 1917 took up work as Deputy Director of Medical Services under the Ministry of Pensions

He made himself an authority on medico-legal questions and especially on the subject of workmen's compensation and functional nervous disease. Outside his medical work Dr. Porter was a well-known Freemason and a magistrate for the County of London, sitting for the Tower Division. He married, in 1901, the second daughter of the Rev. T. H. Richards, and she survives him with two daughters.

GEORGE ARTHUR PHILLIPS, M.R.C.S. ENG., J.P.

Dr. G. A. Phillips, who died on Feb. 18th at his home in Streetly, was born in 1849, and was one of the oldest practising doctors in the Midlands; he was also one of the most active. In the early 'seventies he settled in Walsall, where he soon became a leading man. His unusual charm of manner attracted patients from all classes, whilst his keen professional knowledge caused many of his neighbouring colleagues to seek his aid in a consultant capacity. For many years he was senior surgeon to the Walsall Hospital, and he became president of every medical society in the district. At the time of his death he was the senior magistrate on the Walsall bench, and chairman of the licensing committee. Some years ago Dr. Phillips gave up his own practice, but he continued to act as a locum tenens for one or other of his many friends, and, though well over 70, got about on a bicycle better than many far younger men. "Until quite recently," writes a colleague, "it seemed that he had learned the secret of perpetual youth, for he was a man who never appeared tired. Always about, always on the very top of his work, he set a fine example to his juniors. He was a splendid specimen of the old-fashioned family doctor—the friend and kindly counsellor of his clients."

Dr. Phillips qualified in 1870 from St. Bartholomew's Hospital, and before settling in practice held house appointments both there and at other institutions.

WILLIAM JAMES CAIE, M.B., CH.B. ABERD., J.P.

Dr. W. J. Caie, who died at Edinburgh on Feb. 6th, was a prominent citizen of Bury St. Edmunds and was mayor of the town from 1923 to 1925. The son of the Rev. W. S. Caie, of Enzie, Banffshire, he was born in 1874 and was educated at Fochabers Public School, at the University of Aberdeen and at the Coombe Hospital, Dublin. Before graduating in 1900 he acted as prosector in anatomy at Aberdeen University, and on taking his medical degrees was appointed to the resident staff of the Aberdeen Royal Infirmary. After a short period abroad as medical officer to a Union Castle liner he settled in practice in Bury St. Edmunds. A very busy professional life followed, in the course of which, however, Dr. Caie found time for much work on behalf of the town. He sat on the Council from 1907 until his death, and was an active member of the education committee. As a practitioner he was especially interested in midwifery and gynæcology, and contributed a considerable number of articles to medical journals. He also wrote on other subjects, but his chief recreation was music, of which he was very fond. As a musician, both violinist and singer, he took a share in the social life of the town, and he was chairman of the Bury Operatic Society. A Freemason and a keen gardener, Dr. Caie was a man who had many interests in common with his fellow-citizens, and he threw himself into all his undertakings with energy and enthusiasm. During the late war Dr. Caie served with the 1st East Anglian Field Ambulance from 1914 to 1916, and held rank as major, having for some years been a Territorial officer. He married in 1906, the eldest daughter of Dr. C. S. Kilner, his partner in practice. His widow survives him and he leaves two sons and two daughters.

REBUILDING OF DONCASTER INFIRMARY.—The Doncaster Collieries Association have promised £25,000 to the building fund of the new Doncaster Infirmary "conditionally on the cessation of the outside agitation which has held up the building scheme."

MIGRAINE.

DISCUSSION AT THE ROYAL SOCIETY OF MEDICINE.

A MEETING of the Section of Medicine was held on Feb. 22nd, Dr. HUGH THURSFIELD, the President, being in the chair.

Dr. C. P. SYMONDS opened a discussion on

MIGRAINE

by pleading for a clearer definition, and remarking on the lack of addition to the knowledge of the subject since Liveing's description in 1873. This lack of progress was partly due, he thought, to faults in the technique of observation and the tendency to include in the term "migraine" any obscure form of recurrent headache. Recent work had detached from the general "migraine-headache" group those due to head injury and sinus disorder, but many varieties still awaited proper classification. The term "migraine" should be reserved for that type characterised by "a liability dating from early life to recurrent attacks of headache, which are at one time or another associated with a characteristic visual or sensory disturbance and are frequently accompanied by nausea or vomiting."

The outstanding ætiological factor of migraine so defined was heredity. Of precipitating causes the first was mental stress and fatigue. Others were subject to much diversity of opinion. Various dietetic factors had been indicted: fat, sugar, protein, acidosis, alkalosis, and blood cholesterin. But the clinical data supporting these theories were meagre or unsatisfactory and the biochemical observations had been few. The occurrence of gastro-intestinal disturbance in the early stages of an attack could not be taken as evidence of gastro-intestinal origin. Eyestrain was rarely an important cause.

Symptoms.

The visual and sensory disturbances were worth studying for the light they threw on diagnosis and pathology. The true fortification spectrum with homonymous defect was rare; simple defect with or without vague flashings was more common and might vary from mere dimness to complete loss. It was usually a vertical homonymous hemianopia, sometimes definitely quadrantic, sometimes bilateral, but usually restricted to a part of the field which could be accurately described by the patient. Transverse hemianopia, transient central scotoma and monocular blindness might occur. All the disturbances were rapid in onset and recovery. The sensory phenomena were distinguished from those of sensory Jacksonian epilepsy by the slow spread (10–30 minutes) and by the fact that tingling of lips and tongue was always bilateral, and that both hands might be involved but rarely both legs. If the right hand was affected there might be some aphasia. Sensory and visual disturbances usually occurred apart from each other and before the onset of headache; they might occur without the pain, or be associated with only a small proportion of the patient's headaches. The preliminary warning sometimes took the form of a peculiar sense of lassitude or even of well-being, the day before the attack. The headache was throbbing, splitting, or bursting, often on the side opposite to the hemianopia but nearly as often bilateral. Vomiting might be the predominant feature, especially in children, in whom many attacks of "cyclical vomiting" seemed to be precursors of migraine. Attacks usually began early in the morning. Dr. Symonds reviewed the symptoms from the point of view of their cortical localisation. This would not, however, stretch to include unilateral scotoma or blindness. He doubted whether cases where these phenomena occurred were true migraine; he had not found a well-documented instance.

He concluded, therefore, that the situation of the disturbance lay in the cerebral cortex, particularly in those parts in which vision and sensation are represented, and that the disturbance was often bilaterally symmetrical

Migraine due to Local Vascular Spasm

The nature of the disturbance was a matter of analogy, and the theory of vascular spasm was the most probable and offered the best explanation of the order of the visual phenomena and the symmetry of the disturbance Raynaud's disease provided a striking analogy, and the two conditions often occurred in the same patient He found it difficult to accept DuBois-Reymond's theory, that the arteries were in a state of painful tetanic contraction comparable with cramp, since the visual disturbance usually preceded the sensory or might occur independently The analogy with " blue " Raynaud's disease was more satisfactory, local asphyxia leading to local œdema A very small swelling in the brain gave rise to severe pain Such a sequence might well lead to local hæmorrhage, and examples of migraine during subarachnoid hæmorrhage had been recorded Retinal vascular spasm had been observed with the ophthalmoscope during attacks of migraine Such paroxysmal constriction was probably a purely local disturbance of function in the vessel walls due to some chemical substance in the circulation or functional defect in the muscle Howard Florey had shown that stimulation of the cervical sympathetic trunk and vasoconstrictor centre would not affect the cortical vessels

Treatment

Since the disease was hereditary it was not possible to speak of " cure " Régime was the most important factor in diminishing the frequency and severity of the attacks Luminal and liquor trinitrini were of undoubted value and were worth trying alternately Often the patient found out how best to treat himself in an attack or how to avert it Aspirin and rest might induce sleep and relief or a good meal with a glass of wine might stop the headache

Two lines of investigation should be pursued (1) the effect of various chemical substances upon the cortical vessels, and (2) the clinical and biochemical features of cases of true migraine should be recorded before, during, and after an attack

The Chairman described a peculiarly severe case of long-standing migraine in a medical colleague The symptoms were ocular disturbance to complete blindness, partial right-sided paralysis, and mental confusion The headache could be relieved by phenacetin This was confirmed as migraine by several other observers He could not see how vascular spasm could be as localised as it must be were it the mechanism of the attack

The Importance of Eyestrain

Dr A Hurst disagreed profoundly with Dr Symond's dictum that eyestrain was an inconsiderable factor On the contrary it was the most important cause of that fatigue of a brain centre which determined the attack, and in some cases was the only cause The reason for its lack of recognition was that only exceptionally careful oculists noticed it, for the slightest astigmatism or lack of muscle balance could be of great importance Glasses, too, needed adjustment from time to time, as accommodation varied with many factors, including health Biochemical examinations of migraine subjects showed a perplexing normality, but X rays revealed that during an attack the stomach ceased entirely to act It was important to recognise how many aberrant types there were He had seen cases that had been operated on for all sorts of supposed conditions

Dr F W Collingwood said that he was subject to migraine and had never found the attacks precipitated by reading, but they were worst after exciting debates, especially political ones

The Family Physician's Point of View

Dr J L Morton stressed the importance of hunting for the exciting cause however " idiopathic " and ‘ causeless " the attack might appear " Spontaneous actions did not occur in Nature " The family physician saw the emergence of migraine during child life, when its alarming acute bilious attacks might even be mistaken for appendicitis Very irregular cases were encountered and the collateral symptoms were worth knowing Eyestrain was, in his opinion, the most important liberating stimulus, and not all first-class oculists were equally successful in finding the small error of muscular balance which might be present Uterine and menstrual disorders, especially displacements, intestinal stasis, appendicitis, goutiness, and sluggish action of the liver might precipitate attacks Headache was by no means the only symptom It might be preceded by itching of the scalp for several days, by abnormal hunger by a feeling of buoyancy or depression, or by a habit of awakening earlier each morning A dose of calomel or salts might avert or mitigate the attack After the headache there were also many easily misunderstood symptoms the correlation between belly and brain was particularly well illustrated by migraine Anorexia, unaccountable sickness and nausea—even cardiospasm—might be central in origin and due to vagal disturbance from a migrainous brain The patient was not always better when the headache passed off with advancing years as these gastro intestinal troubles often remained and glycosuria or arterio-sclerosis might appear

The Relation of Migraine to Asthma and Hydrocephalus

Mr F Coke quoted cases associated with asthma, and remarked that skin tests were of no use except on the day when the patient was going to have a migraine attack

Dr. E A Carmichael supported the theory that migraine might be due to an internal hydrocephalus due to a turgescence of the choroid plexus, blocking one or both of the foramina of Monro Migraine might be described as a slow form of epilepsy Some autopsies had supported this theory

Dr J Kingston Barton said that migraine was undoubtedly mixed up with inherited gout, he regarded it as probably due to some material travelling in the blood until it had been eliminated by the intense polyuria which always ended the attack The effect produced on the patient was that of having temporarily no kidneys The vasomotor constriction probably involved not only the brain but all parts of the body, which would account for the contraction of the stomach recorded by Dr Hurst and for the renal condition The precipitating cause must involve some dietetic question

Dr W R Reynell said that when the problem of epilepsy was solved we should know more about migraine He quoted cases showing the correspondence between the two conditions

Dr J A Ryle said that the common factor of inheritance was the reason why epilepsy migraine asthma, and gout were all incurable There was some diathesis in all of them, some sensitiveness which could be fired off by several triggers and which could only be eradicated by a process of breeding They were not diseases, they were diatheses He recalled Lauder Brunton's observation in his own attacks of migraine, of the constriction and hardening up of his superficial temporal artery

Dr H W Nott described the remarkable effects of the thyroid-manganese treatment in asthma and epilepsy

Dr Agnes Savill quoted the experience of a migrainous family whose members found that the attacks could be arrested by salts or sodium salicylate, they could not, therefore, be entirely due to eyestrain

Dr P Macbride said he was convinced migraine was an allergic disease although no doubt eyestrain was a factor in its production A very large number of people had errors of refraction but very few of them had migraine Cases should be investigated on these lines with an inquiry into the family history and a blood count for leucopenia

Dr. **SYMONDS**. in reply. said that he thought much of the difference of opinion was due to confusion of definition From those who stressed eyestrain he asked for careful detailed records of true cases of migraine under his definition and of their cure by the oculist's methods He thought the attack passed over too quickly to be due to hydrocephalus, and that the absence of convulsive phenomena was the difficulty in the way of regarding migraine as a form of epilepsy

---

THE ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION.

A MEETING of this Association took place on Feb 16th at the Cheshire County Mental Hospital, Macclesfield. the chair being occupied by Lieut - Colonel J R **LORD**, the President

Visual Imagery

Prof T H **PEAR** read a paper entitled Recent Investigations on Visual Imagery, with Special Reference to Hallucinations The contribution was in two parts, the first dealing with modern experimental normal psychology. the second with modern psychopathology, and Prof Pear said he was not aware of any writings which attempted to bridge the gap between the two The young German investigators had been very busy on this subject since the war and some of the results were now becoming known in this country Some people were able to vividly visualise things they had seen, such as pictures, maps, diagrams and were seldom conscious of having mistaken the images so conjured up for the realities Popularly the man who mistook images for realities was insane and he who did not was not insane But that did not suffice for a psychological definition for dreaming was within the experience of most people Not only in dreams but in other borderline cases the imagery was very real. And the images in a dream might be very different from the images perceived in the day-time In ordinary everyday life, though we made a very clear distinction between our percepts—i e our experience of the outer world—and what were termed our images, they were interdependent In the case of a motorist passing another motor in the night when the lights of the other car were not switched off, it was not an illusion that the driver of the first car saw the lights after he had passed them: he actually continued to see them for the visual apparatus was still functioning. There were many problems concerning a form of visual memory which was neither an after-sensation nor an ordinary visual image, and this visual memory was termed the eidetic image It was a special memory of an object seen, which some people experienced after the object itself had been removed It was not ordinary memory because details came out in the eidetic image which were not consciously observed in the direct examination This merged into the region of pseudo-hallucination To produce an after-sensation it was necessary to fix one s eyes carefully on one spot in a picture for about half a minute and then continue to fix on the spot for about 20 seconds after the picture had been removed The after-image had not the same colours as the original No one got the eidetic image just as in the picture, those who saw it said it fluctuated sometimes being clear at other times less clear People who got the eidetic image were often those who were devoted to art · some were "unusual" people In Germany it was found that after the fourteenth year the tendency to have these images decreased with the passage of the years unless the adult had the childish type of mind

With regard to the relation of this happening to pseudo-hallucination. Prof Pear gave a remarkable experience in a man who worried about his hallucinations following the war. These eidetic images might occur when the mind regressed to a more childish state, and it was an interesting question how far our modern system of education and culture had educated us out of this habit

Dr. B. H **SHAW** asked whether this eidetic memory was not the same as was spoken of as the artist's memory.

Dr. **DONALD ROSS** asked whether Prof Pear had thought of investigating the auditory sphere in the same way as the visual as auditory hallucinations were the more serious of the two.

Prof **PEAR** replied that the eidetic image was not the same as the artist's memory and many artists did not have a visual imagery while they were drawing. A man who had satisfying visual images did not have the desire to draw at all It seemed that the investigation of auditory pseudo-hallucination was an almost untilled field: these manifestations were usually regarded as grave

Dr K K **DRURY** read a paper on

Ultra-violet Radiation in Mental Hospital Practice.

He said that the Board of Control reported in 1925 that there were, at that time, only five installations of artificial heliotherapy apparatus in mental hospitals He reviewed the history of the use of the photochemical action of light and discussed the relative advantages of the carbon arc, the tungsten arc, and the mercury-vapour arc. The atmospheric air-cooled mercury-vapour lamp was very suitable to the needs of a mental hospital The general health of patients subjected to this treatment was benefited. He considered that the whole subject of dosage and skin reaction was a paradox It was however. found that the best results followed when the rays caused a mild skin erythema Females usually reacted more than did males blondes more than dark-complexioned people and clear-skinned folk more than those with a greasy skin There were three contra-indicating states: agitated melancholics acute maniacs, and epileptics not only did not benefit, under the treatment, but they actually became worse. Simple melancholics manic-depressives, and confused cases seemed to derive definite benefit from the treatment. He referred to the new glazing material vitaglass, which allowed ultra-violet rays to pass freely, ordinary window glass cutting off most of these rays He urged that a careful record be kept of all patients submitted to this treatment. to include weight, pulse, blood pressure, hæmoglobin content, and white cell differential count

The **PRESIDENT** said he hoped this paper would provide a stimulus to other mental hospitals to set up similar installations Horton Mental Hospital. Epsom enjoyed the distinction of having been the first institution of the kind to adopt the treatment Practically all cases with chronic skin diseases ulcers &c.. in the institution were now cured of them. so that the large amount of time which had been spent in dressing these cases could now be devoted to other purposes In the case of a nurse on the staff with a large tuberculous growth in the neck an operation had been decided on, but the light treatment in a short time had made a remarkable cure of it without

---

HOSPITALS AND ACCIDENTS —Last year Manchester Royal Infirmary dealt with 27,677 accidents, the greater number of them street accidents and there is consequently, serious congestion of the waiting list. At Sheffield the Royal Infirmary and the Royal Hospital treated about 5000 motor casualties, 600 of the injured persons were in-patients, some of whom stayed for a considerable time Here again there is a long waiting-list. The number of motor accidents dealt with at Leeds General Infirmary was 946, as compared with 768 in the previous year It is intended in future to send accounts of the cost of treating insured patients to the insurance companies concerned

Medical News.

Sir Wm Dunn School of Pathology Oxford —The school will be opened by the Lord Chancellor of England, Lord Cave, the Chancellor of the University, on Friday, March 11th, at 3 30 P M

London School of Hygiene and Tropical Medicine.—In the recent examinations of the Division of Tropical Medicine and Hygiene, the Duncan Medal has been awarded to H W Kumm

University of London . University College —In connexion with the Centenary Celebrations of the College, an address will be delivered by Prof. E H. Starling on Monday, Feb 28th, at 8 30 P M , who has taken for his subject "A Century of Physiology" Sir John Rose Bradford will preside and academic dress will be worn

Royal Sanitary Institute —A sessional meeting will be held at the Institute, 90, Buckingham Palace-road, London, S W 1 on Friday, March 4th, at 5 P M., when a conference on Public Health Meat Regulations will be opened by Mr. W. Brennan de Vine, veterinary superintendent, Birmingham. Dr Charles Porter is amongst those who will take part in the discussion.

Cambridge Graduates' Medical Club —The annual dinner of the Club will be held at the Langham Hotel on Tuesday, March 1st, at 7 15 for 7 30 P M. Sir Humphry Rolleston, President of the Club, will take the chair All members of the Club are invited to be present, and all Cambridge medical men who are graduates of the University are eligible for membership Application forms can be obtained from the honorary secretaries, Mr R M. Vick, of 113, Harley-street, London, W 1, and Dr F G Chandler, of 1, Park-square West, Portland-place, N W 1

James Mackenzie Institute for Clinical Research —Cutaneous hyperalgesia in abdominal disease was the subject of a paper delivered at the Institute on Feb 15th by Dr A. R McKerrow Speaking of the adequate stimulus required to induce pain and hyperalgesia, he said that Mackenzie had held that since mechanical stimuli such as heat and cutting produced no sensation when applied to viscera supplied from the sympathetic system, the adequate stimulus must be provided by a vital activity, and he had considered that abnormal contraction of non-striped muscle was the source of this stimulus Other authors had suggested increased tension or imperfect drainage of the tissues as the cause, but Dr McKerrow pointed out that tension and obstruction were just the conditions that lead to over-activity of the muscular coat Ligat's view that the mucosa contained the receptors for the viscero-sensory reflex was capable of a similar explanation since stimulation of the mucosa resulted in peristaltic activity. Dr McKerrow drew attention to the cases quoted by Ligat which showed that the area of hyperalgesia was constant, no matter what displacement of the related viscus was present

Fellowship of Medicine and Post-graduate Medical Association —At 5 P M on Thursday, March 3rd, at the rooms of the Medical Society of London, 11, Chandos-street, W 1, Dr Arthur Whitfield will lecture for the Fellowship on the Differential Diagnosis of Some Acute Rashes On Tuesday, March 1st, at 3 15 P M , Dr R Wade will lecture at the Royal Northern Hospital on Safety in Anæsthesia Both lectures will be open to members of the medical profession without fee The Brompton Hospital will hold a course from March 7th to 12th inclusive (fee £3 3*s*), instruction will continue all day except Monday and Thursday and will include demonstrations in the cardiographic and radiographic departments and the wards From March 14th to 25th a course in gynæcology will be given at the Chelsea Hospital (fee £5 5s) A comprehensive course will be undertaken at the Royal National Orthopædic Hospital from March 21st to April 2nd (fee £2 2*s*) and a course primarily for the general practitioner will be held in the late afternoon between the same dates at the London Temperance Hospital (fee £1 1s) From March 28th to April 9th at the Queen's Hospital there will be an all-day course in Diseases of Children (fee £3 3*s*) From March 28th for two weeks the Royal Eye Hospital will give a series of demonstrations on the Diagnosis and Treatment of Diseases of the Eye The Fellowship arranges for practical courses in obstetrics and anæsthetics and also makes arrangements for clinical assistantships in gynæcology Copies of all syllabuses and of the *Post-Graduate Medical Journal* are obtainable from the Secretary of the Fellowship at 1, Wimpole-street, London, W 1

The Wellcome Historical Medical Museum will be closed from Feb 28th until March 14th, 1927

Medical Society of London —The 154th Anniversary dinner will be held at the Grand Hotel, Trafalgar-square, London, W C , on Monday, March 7th, at 7 30 P.M. Sir Humphry Rolleston, the President, will be in the chair

The conversazione arranged by the International Society of Medical Hydrology (vide The Lancet, Feb 19th p 415) will be held on Thursday, March 3rd, at the rooms of the Medical Society of London.

The Mayor and Mayoress of Wandsworth will open a home for nurses at 75, South Side, Clapham Common, S W , on Saturday next, March 5th, at 3 P.M. The home has been established by the Nurses' Fund for Nurses

London Street Accidents —During the last three months of 1926 there were 25,279 street accidents in London, of which 293 were fatal

School for Defective Children in Huddersfield —The Huddersfield Town Council decided on Feb 16th to build an open-air residential school for physically defective children at a cost of £8000

London Natural History Society —On Tuesday, March 1st, at 6 30 P M., Major E E Austen, deputy keeper of the department of entomology of the British Museum, will lecture on Tse-tse Flies and their Significance to Tropical Africa The lecture will be given in Room 40, Winchester House, London, E C , and visitors will be welcome

Pathogenesis and Treatment of Sciatica —By invitation of the authorities of the University of Liverpool, Prof Vittorio Putti, professor of orthopædics in the University of Bologna, will deliver the Lady Jones Lecture on Thursday, March 10th, at 4 P M., in the Surgical Theatre of the Medical School, his subject being New Conceptions in the Pathogenesis and Treatment of Sciatica The lecture will be open to members of the medical profession.

New Convalescent Home for Miners —In the course of a few weeks a convalescent home for South Yorkshire miners will be opened Low Hall, situated at Sealby, near Scarborough, has been acquired for the purpose, and with the alterations and additions will cost £13,000 A sum of £60,000 has been invested to provide for its maintenance and upkeep Residents will be admitted on April 4th It is proposed to start with 30 residents per week, making a stay of two weeks each

Post-graduate Facilities in Manchester —Active preparations are being made in Manchester for medical courses under the control of a special post-graduate committee of the Board of the Faculty of Medicine of the University The first of these will commence in September of this year and the prospectus will be issued at an early date It is hoped to attract to these medical men from outside districts, for many of them will be whole-time courses. In the meantime the individual hospitals of Manchester are carrying on series of lectures specially suitable for local practitioners The Consumption Hospital is in the middle of a course and the St Mary's Hospitals have a course from Feb 18th to April 8th The Royal Infirmary commences its usual series on Tuesday, March 1st Lectures will be given on this and succeeding Tuesdays till the end of May and on Fridays, March 4th to May 27th Cases will be demonstrated in the wards Details may be had from the post-graduate secretaries of the respective hospitals

Seamen's Hospital Society —On Feb. 21st Prince George presided over the annual court of governors of the Seamen's Hospital Society in the place of his brother, the Duke of York, the President As usual this meeting was very largely attended, nearly a thousand people being present It was pointed out in the annual report that the Society's work for the sailor is well known, but it is not so often realised that it does much to facilitate the study of tropical medicine , it was in the wards of a branch of the Society in the Albert Dock that Sir Patrick Manson brought to the notice of the profession the need for a centre of investigation and study of diseases peculiar to hot climates Sir Burton Chadwick, Parliamentary Secretary of the Board of Trade, moved the adoption of the report and acknowledged the services rendered by the Society to the community, and especially to the sailor He also dwelt upon the clinical aspect of the six establishments of the corporation, speaking of the unusual types of patient and the unusual diseases from which they suffer Dr C E Sundell, senior physician of the Dreadnought Hospital at Greenwich, in moving the vote of thanks to Prince George for presiding, expressed appreciation of the fact that the first public utterances of the Prince should be in the cause of hospitals

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

Sale of Food and Drugs Bill

IN the House of Commons on Wednesday, Feb 16th, Mr JACOB presented a Bill to amend the Sale of Food and Drugs Acts, 1875 to 1907 which was read a first time

On Monday, Feb 21st, the Sale of Food and Drugs Bill was read a second time and committed to a Standing Committee

Poor-law Emergency (Scotland) Bill

On Tuesday, Feb 22nd, the Poor-law Emergency (Scotland) Bill was read a second time in the House of Commons and committed to a Committee of the whole House

HOUSE OF COMMONS

WEDNESDAY, FEB 16TH

Tuberculosis in the Navy

Sir PARK GOFF asked the First Lord of the Admiralty the number of sailors discharged from the Navy in 1926 suffering from tuberculosis, and how many of those men were granted disablement pensions —Colonel HEADLAM (Parliamentary Secretary to the Admiralty) replied The number of men so discharged was 197 Of these, six were found to be attributable to the conditions of service and pensions on the attributable scale were awarded

Tuberculosis in the Army

Sir PARK GOFF asked the Secretary of State for War if he would state the number of soldiers discharged from the Army in 1926 suffering from tuberculosis, and how many of these men were granted disablement pension —Captain D KING (Financial Secretary to the War Office) replied The number of soldiers discharged from the Army during 1926 on account of tuberculosis was 222, of whom 64 were awarded disability pensions and 84 were awarded non-attributable gratuities

Pensioners with Valvular Heart Disease

Mr BECKETT asked the Minister of Pensions whether he was aware that organic heart disease, such as valvular disease, did not usually affect men until middle age, that a man contracting this disease under 30 years of age might be a complete invalid at 45 years of age, and whether he would consider amending the Pensions Warrant to cover young men who contracted valvular disease of the heart as a result of war service and were not incapacitated until more than seven years after discharge —Major TRYON replied I am medically advised that it is most improbable that a young man contracting valvular disease of the heart as a result of his war service would not be noticeably incapacitated until more than seven years after discharge Should such an exceptional case arise it would be considered in accordance with the special arrangements to which I have already more than once referred in this House

First-aid Outfits on Motor Coaches

Mr RAMSDEN asked the Minister of Transport whether, in view of the numerous accidents to motor coaches and other similar vehicles, he was prepared to make it compulsory that a first-aid outfit should be carried on all such vehicles —Colonel W ASHLEY replied While I view with considerable satisfaction the action of many operators of public service vehicles in equipping their vehicles with first-aid outfits and appliances, and in training their employees in their use, I do not think it would be reasonable to make the provision of such equipment compulsory, nor, indeed, have I at the present time any powers in the matter

THURSDAY, FEB 17TH

Alcohol and Miners' Nystagmus

Mr FORREST asked the Home Secretary whether his attention had been called to a compensation case in Yorkshire in which it was stated that nystagmus was improved by excessive drinking and whether he possessed any reliable information as to the effect of stimulants on this malady.—Sir W JOYNSON-HICKS replied I have no knowledge of the case mentioned by the hon Member, but I would refer him to the findings of the Miners' Nystagmus Committee of the Medical Research Council who deal with this subject on page 50 of their first report It appears that while large doses of alcohol may have a very transient effect in lessening, for an hour or so, the oscillations of the eyes, the influence of alcohol, generally speaking, is markedly harmful and delays recovery

Completion of School Medical Service

Mr COVE asked the President of the Board of Education whether he had asked local education authorities to reconsider their programmes under the head of special services, with a view to substituting proposals in regard to the school medical services in place of proposals involving additional special school accommodation.—Lord E PERCY replied The following is the relevant passage in Circular 1388 of Feb 11th, 1927, to which the hon Member refers —

> *Special Services* —Under this head the Board felt that the first aim of national policy should be the completion of the School Medical Service It will be understood that the Board do not underrate the value of special schools but while no rule can be laid down which is universally applicable to all areas and to all types of physical defect, the completion of the School Medical Service would appear to be of primary importance, and the Board suggest that authorities should concentrate on this definite aim. With regard to provision for mentally defective children, authorities will be aware that this very difficult problem is now being explored by a special committee and, save in exceptional circumstances, it would not seem prudent to incur heavy expenditure at the present moment on new schools for such children or on enlargements of existing schools The adoption of such a policy may make it necessary for authorities to reconsider their programmes under this head, and in some cases to substitute proposals in regard to the School Medical Service for proposals involving additional special school accommodation

Open-air Schools for Invalid Children

Mr BARKER asked the President of the Board of Education if he was aware that Sir George Newman in his last report stated that 57,395 children attending school in 1925 were suffering from latent tuberculosis, malnutrition, debility, and anæmia, and what steps had been taken to provide the necessary open-air recovery schools for such children —Lord E PERCY replied The answer to the first part of the question is in the affirmative As regards the second part, it must not be assumed that additional accommodation is required in open-air schools for anything approaching the number of children mentioned, since most of these children would need to attend open-air schools for only a relatively short period In the past 18 months the accommodation in open-air schools has been increased by some 900 places, and proposals have been approved for over 1500 further places, apart from proposals now under consideration In addition, a number of local education authorities have included proposals for new open-air schools in their programmes

Slum Clearances

Mr TREVELYAN THOMSON asked the Minister of Health how many towns had begun slum clearances under the Housing Act of 1919 and subsequent Acts —Mr CHAMBERLAIN replied The position in regard to the clearance of slum areas in England and Wales is as follows 93 schemes relating to 71 local authorities have been confirmed since 1919 On Jan 1st last tenders had been approved or loans sanctioned in respect of 74 schemes for the erection of new houses in order to provide accommodation for the displaced population and to enable clearances of the areas to be commenced In the case of 72 schemes the areas had been wholly or partially acquired, and clearance was in progress in the case of 56 schemes

Minister of Health and Medical Officer's Salary

Mr WOMERSLEY asked the Minister of Health if he was aware that the Lindsey County Council recently advertised for a lady doctor as an assistant to the medical officer for Lindsey at a salary of £400 per annum, plus travelling allowances; that 15 applications were received from properly qualified persons, that the approval of the Ministry of Health to such appointment had been withheld, and on what grounds the appointment could not be approved —Mr CHAMBERLAIN replied The answer to the first and third parts of the question is in the affirmative As regards the second part, I have no official information as to the number of applicants for this post or as to their qualifications As regards the last part, I should not be able to approve this appointment as I am not satisfied that it would be possible to obtain for the salary proposed an officer with the necessary qualifications and experience of the important work attaching to this post or one who would be likely to secure the coöperation of the medical practitioners in the county

Insulin and Diabetes

Brig -Gen BROOKE asked the Minister of Health whether his medical officers were still recommending the use of insulin for the treatment of diabetes, and whether, in view of the attacks now being made on this remedy, he would define the position of his department —Mr CHAMBERLAIN replied It is not ordinarily part of the duties of medical officers of the Ministry to make recommendations in regard to treatment, though regional medical officers may occasionally offer suggestions at the request of an insurance practitioner As regards the second part of the question, I am advised that the administration of insulin is unquestionably of great value in suitable cases I may add that the mortality-rate from diabetes does not appear to be increasing, although the number of deaths from this disease naturally tends to increase with the increase in the population.

Medical Examination of Assisted Emigrants

Mr RAMSDEN asked the Minister of Health whether he had considered the recommendation made by the inter-departmental committee appointed to consider the effect on migration of schemes of social insurance that the 10*s* 6*d* fee for the medical examination of those seeking assisted passages should be paid from national health insurance funds, and what action he proposed to take —Mr CHAMBERLAIN replied I have considered the recommendation to which the hon Member refers Legislation will be required to give effect to it, and I hope to include the necessary provision in the next Bill relating to national health insurance

Offences against Young Persons

Viscount SANDON asked the Minister of Health what action, legislative and administrative, he proposed to take on the subject of the Report of the Committee on Offences against Young Persons —Sir W JOYNSON-HICKS replied. As regards administrative action I have already commended the Report to the consideration of magistrates and the police Whether any, and if so what, legislation should be proposed is a matter which will be better considered when the Committee on Youthful Offenders, which is now sitting, has made its report Effect was proposed to be given to Recommendation 27 in the Mental Deficiency Bill of last session

Cleanliness of Imported Dairy Produce

Brig -Gen CLIFTON BROWN asked the Minister of Health whether, in view of the fact that neither the Imported Milk Regulations or the Milk and Dairies Order apply to Ireland, the Channel Islands, or the Isle of Man, any inspection was made at the ports or elsewhere of milk and dairy produce coming from those places, or what was the procedure adopted to ensure clean imports of dairy produce —Mr CHAMBERLAIN replied I understand the position to be that no milk is imported into this country from Ireland, the Channel Islands, or the Isle of Man Dairy produce brought from them is subject, under the Imported Food Regulations, to the same inspection at the ports as dairy produce brought from other countries

New Mental Deficiency Institution at Clayton Heights

Mr WILLIAM HIRST asked the Minister of Health when the plans for the new mental deficiency institution at Westwood, Clayton Heights, which had been under consideration by the Board of Control for the past two and a half years, were likely to receive the approval of the Board.—Mr CHAMBERLAIN replied. I am informed that the Board of Control are awaiting the submission by the local authority for approval, of the completed plans, specification, and estimate. The Board will deal with them at once on their receipt

Cost of Mental Patients

Mr. ROBERT RICHARDSON asked the Minister of Health what was the cost to the local authorities for the maintenance of the mental patients chargeable to them, together with the amount granted by the Exchequer in relief of such cost, for the years 1913–14 and 1925–26, respectively — Mr. CHAMBERLAIN replied The total expenditure of local authorities in England and Wales other than out of loans in connexion with mental patients in county and borough asylums was £4,305,000 in 1913–14 and £8,087,000 in 1924–25 This expenditure was met out of the following sources —

	1913–14	1924–25*
Repayments by relatives and others	£612,000	£1,668,000
Specific Government grants	£955,000	£1,010,000
Other sources, mainly rates . . .	£2,738,000	£5,379,000

* Figures for 1925–26 are not yet available

The Mental Deficiency Act, 1913, was not in force in 1913–14 The total expenditure of local authorities in 1924–25 on mental deficiency other than out of loans was £941,000, which was met as to £102,000 from receipts from relatives, &c, as to £392,000 from specific Government grants, and as to £447,000 from other sources, mainly rates

New Accommodation for University of London

Sir WILLIAM DAVISON asked the Chancellor of the Exchequer whether, arising out of the promises made by him to the University of London last June, any plans for the additional accommodation required for the headquarters of the University at South Kensington had been submitted; and whether any land had been purchased from the Bedford Trustees for housing the Institute of Historical Research and the Students' Union at Bloomsbury —Mr CHURCHILL replied: The answer to both parts of the question is in the negative

Fatal Accidents in Coal-mines

Mr. THOMAS WILLIAMS asked the Secretary for Mines the number of fatal accidents which occurred in the coal mines of Great Britain between May 1st and Dec 1st, 1926, and the number of fatal accidents which had occurred since Dec 1st —Sir P. CUNLIFFE-LISTER (President of the Board of Trade) replied. From the beginning of May to the end of November 1926, there were 141 fatal accidents at mines under the Coal-mines Acts, causing 145 deaths For the period Dec 1st, 1926, to the end of January, 1927, the corresponding figures were 164 and 173

MONDAY, FEB 21ST

Ministry of Health

On a supplementary estimate of £220 000 for the Ministry of Health,

Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) said that £350,000 was required under this vote for sickness and disablement benefit under the National Insurance Act, and in addition there was a sum of £13,000 for Wales As in Scotland they had found in England and Wales that during the current financial year, although there had been for the most part no prevalence of any marked epidemic or exceptional outbreak of sickness there had been a wholly exceptional increase in claims on certain approved societies especially in the coal mining areas, and the same conditions have led to an increased expenditure on drugs necessitating an extra grant of £25,000 It was estimated that after making an allowance for the increased amounts distributed as additional benefits the claims experience of the approved societies have exceeded that of 1925 by no less than £2,309,000, and it was very significant that the rate of increase and the expansion of sickness benefit was not uniform throughout the country, but that its geographical distribution had corresponded very closely with the incidence of unemployment due to the coal dispute He agreed that in times of industrial depression one might naturally look for some measure of increased sickness But in reviewing the situation in June, the Minister and everyone concerned in the matter could not escape the conclusion that there were large numbers of insured persons who had succeeded in obtaining medical certificates although they were not in fact incapable of work within the definition of the National Insurance Act, and this fact had been confirmed by the very large number of cases that were referred to the medical referees There had been a very high proportion of claimants who, when they were referred to the medical referees signed off in preference to presenting themselves for examination, and in this supplementary estimate there was an extra sum of £30,000 spent in the increased employment of medical referees The normal number of people who were referred to medical referees by approved societies under the National Insurance Act every year was about 200,000. In the period referred to—from the beginning to the end of the coal stoppage—the societies referred between 400,000 and 500,000 persons to the medical referees Of these people some 40 per cent. signed off in preference to presenting themselves for examination, and as for the remainder the examination proved that only 66 per cent. were incapable of work compared with the normal 80 per cent As far as ordinary foresight could see, this was an unforeseen and unfortunate experience so far as national insurance was concerned, which everyone hoped would not be repeated. He did not think that anyone could blame the Department or the approved societies or the actuary for the undoubtedly disastrous consequences which followed the recent industrial dispute So far as they could judge at the Ministry things were now rapidly approaching the normal, and the normal rate of sickness insurance experience would, he hoped, soon be reached. There were other items in the vote which were of a more pleasant nature One arose in connexion with a dental service which was for the first time being inaugurated in connexion with national insurance The money was required for the salaries of the regional dental officers for the last two months of the present financial year Out of the surpluses available for additional benefits as a result of the second valuation of approved societies £2,000,000 have to be re-allocated to pay benefits under the additional benefit scheme, and 6300 societies were engaged in administering this extra benefit

Mr. WHEATLEY said he would move the reduction of the vote by £100 as a protest against the attack which had been made on the medical profession The hon. Member's statement with regard to an honoured and honourable profession could not go unchallenged or uncriticised in that House It amounted to this that during the coal stoppage large numbers of the medical profession were guilty of fraud, and that they were aided and abetted in carrying out their fraudulent policy by large masses of the working classes in this country There was no use mincing matters If it were true as the hon Member speaking for the Government alleged, that the approved societies had been deprived of large sums through members of the medical profession granting certificates that were not warranted, then those medical practitioners were guilty of a very gross system of fraud That was not the view of the medical profession which he had learned from his experience in life or during his brief experience as Minister of Health He had always been taught to look up to the medical profession as being among the most honourable sections of the community and he was sure that they would read with amazement the statements made on behalf of the Government that day He left the Government and the medical profession to settle this between themselves He had no doubt that the medical profession would find means of clearing their character of this unjust imputation cast upon them by the Ministry of Health

Miss WILKINSON said that those who knew the mining areas knew the amount of pressure that was brought to bear on doctors to prevent them putting anyone on the fund they could possibly keep off The statement of Sir Kingsley Wood was the most appalling condemnation of the whole policy of the Ministry of Health throughout the mining dispute. Sir Kingsley Wood's statement was not only a libel on the medical profession but an insult to the intelligence of the Committee The doctors at any rate behaved like decent citizens, and as men with some humanity They tried to get food for these unfortunate men whom the Ministry of Health tried to starve

Dr. VERNON DAVIES said the compliments of Miss Wilkinson to his profession were rather of a back-handed nature, because she said that medical men had put men on to medical benefit who ought not to have been put there That meant that they were in fact doing a dishonest act that they were men of dishonour Malnutrition was not a disease for which a medical benefit could be given and if a doctor put on a medical certificate that the person was suffering from disability or malnutrition, the approved society would not accept the certificate The question which had been raised by the Parliamentary Secretary that evening opened up a very wide subject and brought to the front one of the inherent defects of the National Insurance Act which they recognised was bound to come up some time Sir Kingsley Wood's allegation against the medical profession was a most serious one and ought to be most carefully examined Doctors were human beings like their patients They had hopes and desires and anxieties too, and while in practice they were anxious not to offend their patients unnecessarily Two curious facts were (1) that as soon as the coal stoppage was over, there was a sudden drop in the benefits, and (2) that the approved societies sent a larger number of cases to the medical referees But one of the peculiarities of the Insurance Act was that a person could do no work, or he could do full work. He could not do part work. A doctor could not say that a person was suffering from disability, he must give it a definite name. In his own practice very often he thought that a patient was well enough to do light work, but the patient said, I really have not the strength to do the amount of work I had to do ' and he (Dr Davies) had to take his word The panel doctor was practically in the hands of his patient He might have a strong suspicion, but if he persisted in signing the patient off the patient would go away and tell all his friends "Dr So-and-so has signed me off He is a brute Don't you ever go to him." That went round and the doctor lost 10, 20, 50 or a 100 panel patients It was very difficult for a doctor to prove whether a man was fit for work. Supposing a man said ' I have a pain in my back, and the doctor examined him and said "I cannot find any pain." The patient replied ' No, but I feel the pain. What could the doctor do in that case? So that although he thought that the doctors perhaps were under a little suspicion, that they were a little too lenient and did not exercise sufficient care in sending patients back to work, the main result that they should judge from this supplementary estimate was that a certain number of people finding that they were locked out and could not get relief from the Poor Law suddenly remembered that there was such a thing as the panel doctor Having got on the benefit list they took good care that they did not get off until they were absolutely fit and strong That perhaps was human nature So long as they had national insurance on its present basis they would have that difficulty to face The result was that the moral of the patients and the moral of the doctor in some cases was sapped

Sir KINGSLEY WOOD said that he had not challenged the position of the medical profession in this matter, but as they had been challenged, it was right to point out that the doctors themselves had taken action The matter had not escaped their notice or that of the approved societies In July last the Minister of Health communicated with the appropriate authorities, and in October the National Health Insurance Commissioner attended a representative conference and put the whole of the facts before the medical men. The conference passed a resolution that the Insurance Acts Committee be asked to consider what practical steps could be taken to meet the difficulties raised by the National Health Insurance Commissioner and that in the meantime the representatives of the local medical panel committees pledged themselves to use their influence locally in endeavouring to secure strict adherence to the principles governing certification for purposes of the National Health Insurance Acts He hoped therefore that it would not be thought that he had over-stated the case or that medical men themselves were not alive to the evils arising from the state of things which he had indicated He recognised the difficulties of the doctors but he would emphasise the fact that in the interest of national health insurance and of the other contributors to the fund if they once did away with the fundamental test of capacity for work, they destroyed the whole financial basis of national insurance

On a division the vote was agreed to by 187 votes to 78

TUESDAY, FEB 22ND

Number of Insured Persons

Mr HERBERT WILLIAMS asked the Minister of Health the estimated number of persons insured under the National Health Insurance Act on Dec. 31st, 1926 and, for comparison the number on Dec 31st, 1925 —Mr CHAMBERLAIN replied: The approximate number of persons insured under the National Health Insurance Act in England and Wales on Dec. 31st 1925, was 14,196,000 The necessary information is not yet available to enable the number insured on Dec 31st, 1926, to be furnished for comparison, but I am advised that they are roughly the same as in the previous year

Rejection of Recruits for Air Force

Mr HORE-BELISHA asked the Secretary of State for Air how many applicants were accepted in the year 1926 for His Majesty's Air Force, and how many were rejected on account of some physical or medical disability —Sir S HOARE replied The answer to the first part of the question is 379 men and 1037 boys, to the second 258 men and 34 boys

THURSDAY—11 30 A M, Dental Clinic 2 30 P M to 5 P M, Medical, Surgical, and Ear, Nose, and Throat Clinics Operations

FRIDAY—10 30 A M, Throat, Nose, and Ear Clinics 2 30 P M to 5 P M, Surgical, Medical, and Children's Diseases Clinics Operations

On MONDAY, Feb 28th, and TUESDAY, March 1st, there will be special demonstrations of Medical Cases and Surgical Cases by Dr A J Whiting and Mr W E Tanner respectively

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S W

TUESDAY, March 1st—5 P M, Dr F. Dearden Health Hazards in the Cotton Industry (First Milroy Lecture) THURSDAY—5 P M, Second Milroy Lecture

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W C

WEDNESDAY, March 16th—5 P M, Dr Hildred Carlill Simulation of Surgical Affections by Hysteria (Arris and Gale Lecture)

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL, Gray's Inn road, W C

FRIDAY, March 4th.—4 P M, Mr Watkyn Thomas

LONDON SCHOOL OF DERMATOLOGY, St John's Hospital, 49, Leicester square, W C

TUESDAY, March 1st—5 P M., Dr Wilfred Fox, Cutaneous Syphilis (1)

THURSDAY—5 P M, Dr Wilfred Fox Cutaneous Syphilis (2)

ROYAL NORTHERN HOSPITAL POST-GRADUATE COURSE.

TUESDAY, March 1st—3 15 P M, Dr R Wade Safety in Anæsthesia

HOSPITAL FOR SICK CHILDREN, Great Ormond street, W C

THURSDAY, March 3rd—4 P M, Dr A M H Gray Ringworm

PEOPLE'S LEAGUE OF HEALTH (Sims Woodhead Health Lectures)

MONDAY, Feb 28th.—6 P.M (at the Medical Society of London, 11, Chandos street, W), Dr H Gardiner Hill· Internal Secretions as Factors in Nutrition

MANCHESTER ROYAL INFIRMARY, POST GRADUATE COURSE

TUESDAY, March 1st—4 15 P M, Mr John Morley· Graves's Disease from the Surgical Standpoint

FRIDAY—4 15 P M, Mr P R Wrigley Demonstration of Surgical Cases

ST MARGARET'S HOSPITAL FOR WOMEN, Acomb street, Whitworth Park, Manchester

WEDNESDAY, March 2nd—4 15 P M, Mr A. C Magian· The Use and Abuse of Gland Extracts in Gynæcology

ST MARY'S HOSPITALS, Manchester

FRIDAY, March 4th—4 30 P M (at the Whitworth street, West Branch), Post graduate Lecture, Dr F H Lacey A Visit to the Wards

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS,

FRIDAY, March 4th—3 30 P M. (at the Royal Hospital) Dr Skinner Neurological Cases

Appointments.

MAILER, R M D Edin, F R C S Edin, has been appointed Assistant Surgeon, Victoria Infirmary, Glasgow

THOMSON, M SYDNEY, M D Camb, M R C P Lond, Junior Physician to the Skin Department at King's College Hospital

Royal Free Sussex Hospital GABB, H S, M B, Ch B Camb, Honorary Surgeon, CAIGER, G H, M B Camb, F.R C S Eng, Assistant Surgeon

Vacancies.

For further information refer to the advertisement columns

Barry Urban District Council, Accident and Surgical Hospital—S £750

Bristol Royal Infirmary—H P's, H S's, Dental H S, &c Each at rate of £80

Burton-on-Trent Infirmary—H S Jun Res H S £150

Carshalton Surrey, Queen Mary's Hospital for Children—Jun. Asst M O £500

Chesterfield and North Derbyshire Royal Hospital—Fifth H S. At rate of £100

East Riding Mental Hospital, Beverley—Med Supt £900

Federated Malay States, Central Mental Hospital—Second Asst. Med Supt £700

Great Yarmouth County Borough—Asst M O H, &c £600

Holland (Lincs) County Council—Asst M O H £600

Hospital of St John and St Elizabeth, 40, Grove End-road, N W—Asst P

Hospital for Tropical Diseases, Endsleigh gardens, W C—Med. Supt £250

Hull City Education Committee—Asst Sch M O £600

Ipswich, East Suffolk Administrative County—Asst County M O H, &c £625

Leicester Royal Infirmary—H S and H P At rate of £125 and £120 respectively

Leicestershire County Council—Asst County M O £750

London, Female Lock Hospital, 283, Harrow road, W—Surg Res. £100

London Jewish Hospital, Stepney Green, E—Med Reg and Out patient Asst Also Surg Reg Each £50

London Lock Hospital, 91, Dean-street, W—Surg Reg £100

Manchester, Ancoats Hospital—Hon Phys

Manchester, Baguley Sanatorium—Asst M O £350

Manchester, Royal Children's Hospital, Gartside street—Asst M O· At rate of £150 Also Res Surg O At rate of £80

National Hospital, Queen-square, W C—Res M O £200

Nottingham City Mental Hospital—Jun Asst M O £350

Nottingham General Hospital—H P At rate of £150

Oxford, Radcliffe Infirmary and County Hospital—H P and Cas H S Each at rate of £120

Royal Free Hospital, Gray's Inn road, W C—H P to Children's Dept

Royal National Orthopædic Hospital, 234, Great Portland street, W—H S At rate of £150

St Marylebone Hospital, Ladbroke-grove, W—Third Asst M O £300

St Mary's Hospital for Women and Children, Plaistow, E—Hon. Asst Surg

St Mary Islington Infirmary, Highgate Hill, N—Asst M O At rate of £350

St Peter's Hospital for Stone, &c, Henrietta street, Covent garden, W C—H S At rate of £75

Samaritan Free Hospital for Women, Marylebone road, N W—H S At rate of £100

Southend on Sea County Borough—Asst M O H, &c £600

Southampton, Royal South Hants and Southampton Hospital—Jun H S At rate of £150

Surrey, Redhill, Royal Earlswood Institution—Jun Asst M.O At rate of £250

West Bromwich County Borough—Asst M O H £600

West London Hospital, Hammersmith-road, W—H P and two H S's Each at rate of £100 Also Hon. Med Reg £100

Western Ophthalmic Hospital, Marylebone road, N W—Sen and Jun Non-Res H S's At rate of £150 and £100 respectively

Willesden Municipal Hospital—Res M O £150

Yeovil Union—M O, &c £230

The Chief Inspector of Factories announces the following vacant appointments for Certifying Factory Surgeons Audley (Staffs), Calvert (Bucks)

Births, Marriages, and Deaths.

BIRTHS.

Barclay—On Feb 20th, at 2, Greenhead road Huddersfield, the wife of William Barclay, M B, F R C S Edin, of a son

Borham—On Feb 14th, at Marsham street, Westminster, S W, the wife of John Douglas Borham, M R C S, L R C P, of the Royal Army Medical Corps, of a son

Pope.—On Feb 16th, at Bournemouth, the wife of Surgeon-Captain W H Pope, O B E, R N (retired), of a daughter

MARRIAGES

Lean—Palmer—On Thursday, Feb 17th, at St Margaret's, Streatham on Hill, Oscar Bevan Lean, M R C S, L R C P, to Winifred Mary, daughter of Mr C Palmer and the late Mrs Palmer, of Brixton, S W

Mavor—Jenkins—On Feb 12th, at S Matthew's, Westminster, Hilary Mavor, M R C S, L R C P to Evelyn, daughter of Brig-Gen N F Jenkins, C M G, C B E, of Greycoat gardens, S W

DEATHS

Guillemard—On Feb 18th, suddenly, at a nursing home, after a long illness, Bernard James Guillemard, M D, O B E, formerly of Rondebosch, Cape

Knight—On Feb 17th, at Lytton avenue, Letchworth, Herts, Charles Frederick Knight, M D, M R C S, L S A, aged 85

Parson—On Feb 14th, Francis John Parson, M R C S, L R C P, of "Ryecroft" Weybridge, and late of Cape Town, in his 80th year

Phillips—On Feb 18th, at Hardwick Lodge, Streetly, George Arthur Phillips, J P, M R C S, in his 78th year

Porter—John Fletcher Porter, C B E J P, M B Lond, of 206, Upper Clapton road, London, died on Feb 17th, aged 54

Weeden—On Feb 14th, at Royal terrace, Weymouth, Alfred Douglas Weeden, M R C S, L R C P, aged 32

N B—A fee of 7s 6d is charged for the insertion of Notices of Births, Marriages and Deaths

Queen Alexandra Memorial—Speaking at a meeting at Birmingham to inaugurate a local appeal on behalf of the National Memorial to Queen Alexandra, the Duke of Portland, the President, stated that the present total of the fund is £171,000, of which £71,000 has been given by Scotland

St Mark's Hospital—At the annual meeting of St Mark's Hospital, City-road, held at the Mansion House on Feb 18th, the Lord Mayor (Sir Rowland Blades), who presided, quoted the striking increase in the hospital's work and a long waiting-list of patients in justification of the construction of the new wing now in course of erection Mr Swinford Edwards and Sir C Gordon Watson spoke of the pioneer character of St. Mark's which had led to the reception of patients from all over the kingdom, cases of peculiar difficulty and complexity affecting the colon and bowel tending to gravitate to the institution A gratifying circumstance of the meeting was the promise of a gift of £500 by Mr Sheriff Shepherd towards the £5000 still to be raised for the Extension Fund

Notes, Comments, and Abstracts.

THE INFLUENCE OF JOHN HUNTER UPON EARLY AMERICAN SURGERY

Being the Hunterian Lecture delivered before the Hunterian Society at the Mansion House, London, on Jan 17th, 1927,

By John M T Finney, MD,

PROFESSOR OF CLINICAL SURGERY AT JOHNS HOPKINS HOSPITAL, BALTIMORE, SOMETIME PRESIDENT OF THE AMERICAN COLLEGE OF SURGEONS AND CHIEF CONSULTANT IN SURGERY TO THE AMERICAN EXPEDITIONARY FORCE

(*Concluded from p 422*)

It has been frequently stated that American medicine really had its beginning with the close of the Revolutionary War and the development of a national consciousness

This was the great formative period of American medicine Its swaddling clothes were being laid aside for garments of maturer years The profession was being gradually emancipated from dependence upon and subservience to European theories and institutions While the great mass of the profession were as yet neither learned in science nor skilled in practice, still there were to be found, scattered here and there throughout the widely expanding country, those who had attained some degree of proficiency in both

The Direct Influence of Hunter

A review of the medical men of prominence in America during the latter part of the eighteenth century and the early part of the nineteenth shows a surprisingly large number of those who had received their surgical training either in whole or in part under John Hunter or one of his pupils The number of these is so large that I can here do no more than call attention to a few of the more eminent among them, giving only a very sketchy outline of their work and the more important contributions they made It might be well, in passing, to emphasise the fact that John Hunter's influence was general, not local Although at first more manifest in Philadelphia, because of the rather extraordinary group of young men from that city who were his earliest American students, it was to be found extending even to the then far Western frontier, carried there by such men as Ephraim McDowell of ovariotomy fame, and Benjamin Dudley, voices crying in the wilderness, preparing the way for the great advances in scientific medicine to follow

If time allowed it would be interesting to attempt to trace, step by step, the influence exerted by John Hunter in America down through one surgical generation after another to the present day So virile and dominating was his influence that it may be readily recognised and transmitted like other distinguishing hereditary traits Take, for example, my own former chief, the late Prof William S Halsted While his early training had been received in the New York School of Surgery, founded by John Jones, his later and predominating views were largely coloured by his continental experiences and associations covering an extended period Nevertheless, John Hunter has never had a more enthusiastic champion or more understanding exponent of his principles of scientific surgery than Halsted His habits of thought and action were throughout characteristically, perhaps unconsciously, Hunterian. That he admired him greatly is evidenced by the fact that his own laboratory of scientific research at Johns Hopkins Hospital, established for purposes of animal experimentation, bears the name of Hunter—"The Hunterian Laboratory"

To one who has had the good fortune, as I have, to have been connected, from its beginning, with the Johns Hopkins School of Surgery, founded by Halsted, the greatest of American surgical teachers, it is easy to recognise in his pupils many of the traits that have characterised the Hunterian School In the various surgical clinics and medical schools scattered throughout the United States, headed by former students trained by him, the same general methods and ideas are being promulgated, and thus the seed sown by Hunter so many years ago is being continually replanted and perpetuated by succeeding generations

Medical Journals and Museums

But another powerful means of diffusing medical knowledge and promoting the welfare of the profession by means of the printed page was inaugurated *about this time*—namely, the first of the long line of medical periodicals in the United States of America. The *Medical Repository* was founded in New York in 1797 by Samuel Mitchell, Elihu Smith, and Edward Miller, the first named of whom studied for a term of years in both Edinburgh and London, where he attended Mr Hunter's lectures, and undoubtedly was stimulated by him to record facts as well as to observe them. Smith, a brilliant product of the Philadelphia Hunterian School suffered an untimely death from yellow fever The *Repository* was a quarterly journal and its pages contained many of the ablest medical and scientific productions of the period It and its successors rapidly became powerful auxiliaries in the cause of medical education and the diffusion of knowledge

The predominating influence exercised by John Hunter over medical thought in the United States is still further emphasised in the collection of anatomical specimens and the formation of museums, a passion with him John Collins Warren, the founder of the Warren Museum of Harvard Medical School and as we will see in a moment one of the founders of the Massachusetts General Hospital as well, was a student under the famous coterie of Hunter's pupils at Guy's and at St Bartholomew's at the beginning of the nineteenth century, where, almost at first hand, he learned Hunter's methods From them he acquired the taste for making and preserving anatomical specimens His grandson still living, who bears the same distinguished name, now professor of surgery, emeritus, of Harvard University, my former teacher, in a personal communication writes me thus "I have no doubt that Hunter's example stimulated my grandfather, John Collins Warren, to carry out this work"

Caspar Wistar who succeeded William Shippen as professor of anatomy in the University of Pennsylvania, was the author of "A System of Anatomy," now almost forgotten, the earliest treatise on anatomy published in this country "His description of the ethmoid bone was classical His memory survives in the Wistaria Vine, which was named after him" He was the founder of the present Wistar Institute of Anatomy and Biology in Philadelphia He too, while studying in London came under the spell of Hunter's influence Sir William Osler, in an address entitled the Leaven of Science, delivered at the opening of the Wistar Institute writes "It is pleasant to think that direct from John Hunter came the influence which made anatomy so strong in this school, and the zeal in the acquisition of specimens which ultimately led to the splendid collections of the Wistar-Horner Museum"

Teaching Hospitals

In 1769, on the occasion of the conferring of the first medical degree by King's College in New York, Samuel Bard, the same who it will be recalled, was largely instrumental in the founding of the King's College Medical School, delivered a discourse upon the Duties of a Physician In the course of this address (which seems to have been hardly less effective than that delivered in Philadelphia in 1765 by his friend John Morgan in connexion with the opening of the Philadelphia Medical College) Bard laid especial emphasis, upon the usefulness, indeed the necessity, of a public hospital, as a most efficient means of relief for the suffering of the sick poor as well as for the instruction of medical students He also emphasised the prime importance of its immediate establishment So convincing were his arguments that the effect of this address upon his audience was immediate and pronounced A hospital building, the forerunner of the present New York Hospital, was shortly afterwards begun When about completed, in 1773, the building was destroyed by fire, so that the opening of the hospital was delayed until the year 1791 During all of this time, and for many years thereafter, Dr Bard first supervised its construction and then served as one of the visiting staff This man, who was so influential in the medical life of New York and who was founder of both its first medical school and hospital, had been a pupil at Edinburgh and under Hunter in London

The next hospital, and to this day one of the finest appointed and best of its kind in the States—the Massachusetts General Hospital—was founded in Boston in 1811 by John Collins Warren, the founder of the Warren Museum, and James Jackson It was not opened for patients, however, until ten years later In their circular letter appealing to the public for funds this significant statement appears, "A hospital is an institution absolutely essential to a Medical School" An early enunciation of a principle long since established

John Collins Warren and the Introduction of Anæsthesia

Warren, one of the most interesting and productive of the group in the Hunterian era of American surgery, was a member of a family whose name has been well known in the surgical annals of the United States from pre-revolutionary times down to the present day Born in Boston and graduated at Harvard, he went to London in 1799, where as a dresser at Guy's Hospital he came, as has been stated, directly under the influence of the two Coopers, William and Astley, with the latter of whom there was formed a friendship that lasted throughout life. He also took advantage of the opportunities offered for study at the clinics of Cline and Abernethy at St Bartholomew's and of Home at St George's From these he learned the new science of surgical pathology so recently inaugurated by Hunter After some time spent here, he went to Edinburgh for a year, then to Paris for another year He then revisited London for a period, and returned home in the autumn of 1802 At once he became associated with his father as prosector for his anatomical lectures at Harvard, and succeeded him as full professor in 1815. Shortly after this the *Boston Medical and Surgical Journal*, a weekly publication still in active existence, was formed by the merging of two other journals He became one of its [illegible] editors "But the crowning event of Dr Warren's career was the part that he played in the introduction of surgical anæsthesia On Oct 16th, 1846, he performed a major operation at the Massachusetts General Hospital while the patient was under the influence of ether administered by Dr W T G Morton The experiment was so successful that it was used in other operations on the following day This experience showed that ether as an anæsthetic agent was safe, certain, and complete, a triple feat which announced to the world that what had been dreamed of for many years had become a reality"

Of course, as is well known, Crawford W Long, of Georgia, had performed surgical operations four years earlier, in 1842, under general anæsthesia induced by sulphuric ether. Little publicity, however, had been given to the fact, and to Warren is given the credit for the introduction of ether into general use Both Long with ether and Jones with pylorectomy, as will be seen, because of failure to publish their work, did not receive the credit undoubtedly due to them McDowell was more fortunate in having Lizars as his publicity agent

Philip Physick and Experiments on Sutures

That Hunter's teaching with regard to the value of the experimental method in surgery bore actual fruit there is abundant evidence to be found in a review of the early surgical literature For example, in the *Eclectic Repertory and Analytical Review*, vol vi, p 359, Philip Syng Physick long a student of Hunter's, makes a preliminary report with regard to his experience in the use of absorbable ligatures He says "Having repeatedly experienced considerable delay in the handling of wounds from ligatures applied on divided arteries remaining for a long time in the sore before they could be removed, I have, for many years, been very desirous of avoiding such an inconvenience in the use of ligatures It appeared to me, therefore, that ligatures might be made of leather, or of some other animal substance, with which the walls of a vessel could be compressed for a sufficient time to prevent hemorrhage, that such ligatures would be dissolved after a few days, and would be evacuated with the discharge from the cavity of the wound"

"Under this impression, I requested Dr Dorsey (his nephew) to try the experiment on a horse, by using a ligature of buckskin This was found to answer every purpose, and came away in a few days" He states that he had tried the effect of various other absorbable materials, buckskin, kid, parchment, and catgut, and goes on to say, "future experiments will probably place at the command of the surgeon a variety of these ligatures which may be so selected as to remain the exact length of time he may require" A prophecy long since fulfilled

Philip Syng Physick, with the singularly appropriate name, was the personal friend and one of the favourite pupils of John Hunter He is referred to by medical historians generally as the first great American surgeon, by some as the Father of American Surgery He graduated in arts at the University of Pennsylvania in 1785 After a preliminary course in the office of Dr Kuhn (during which period he attended lectures in the Philadelphia College of Medicine, but did not take his degree), with his father he went to London, and by him was placed under the care of John Hunter, where he became a member of his family for a period of two years "The first intimation of the course of study which his principal wished him to pursue was made in characteristically Hunterian fashion It was given in reply to a question from the father of young Physick as to what books it would be necessary for him to procure for his son's use "Then, Sir, follow me," said Hunter, "and I will show you the books your son has to study," and leading the way from his study to the dissecting-room, he pointed to several bodies, adding, "There are the books which your son will learn under my direction, the others are fit for very little"

Physick assisted Mr Hunter in many of his experiments, and was recommended by him for the position of house surgeon at St George's Hospital It is stated by his biographers that Mr Hunter later invited him to share with him in his professional business, looking to the ent establishment of Physick in London, possibly successor This offer was declined, however, but an be no doubt that Physick "cherished in after memory of John Hunter for whom he felt great tion and more profound veneration than for ier man" Physick returned to Philadelphia in 1792, ortly after was elected to the surgical staff of the lvania Hospital In 1800 he began a course of s on surgery which attracted large numbers and attention, so much so that shortly thereafter the of surgery and anatomy, filled by Shippen, was l and Physick was appointed to the professorship of y, where for 13 years he taught large classes of ts the principles of surgery as learned from his r, John Hunter Through these students, coming all parts of the country, his ideas became widely unated

sick's contributions with reference to the recurring nics of yellow fever, the treatment of ulcers, mechanical ires and rest in the treatment of joint affections and res, especially of the thigh, an improved instrument hotomy, an improved method for ligating the pudic , advances in the treatment of stricture for the ra, a method of stimulating union in case of ununited ire of bone by use of the seton, plastic surgery, forate anus, operations upon the tonsil and the use e stomach-pump—all attest the wide range of his ities in both medicine and surgery Says Dr Welch, ysick was almost as much a mouthpiece of the doctrines hn Hunter in America as was Abernethy in London "

Experimental Pylorectomy in 1779

especial interest, however, is the work of an early rimental surgeon, described by Merrem as "a certain ous professor, highly respected and renowned among medical profession in Philadelphia" Just who was famous Philadelphian is not stated, but after an ustive study of the records and by careful comparison lates and other facts bearing upon the circumstances ted, there can be little doubt, I think, that the author hese experiments was none other than John Jones He a native of Philadelphia, who had returned there to nd the closing years of his life, but who was, as we have a, the first professor of surgery in King's College, New rk, where he had served with distinction for many years Merrem's Thesis, published in Giessen in 1810, the following interesting report appears "A certain famous professor, hly respected and renowned among the medical profession Philadelphia was greatly concerned by the pre- ture death of Dr Middleton, whose death was caused by e hardening and narrowing of the lower orifice of the mach He therefore concentrated his attention on the ost effective remedy for this very dangerous malady e terrible suffering of his beloved friend could not be moved nor even relieved, although the most approved medies of the time were used Nothing, therefore, was ft other than to remove the cause of the disease—that is, extirpate the pylorus This operation seemed involved such serious danger that at the time his friend would not erform it Two years before he had had experiments ade on several dogs, some of them in perfect health, ne a puppy, but they all terminated fatally " Then ollows a more detailed account of the experiments

The Dr Middleton here referred to was none other than eter Middleton, a member of the first medical faculty of King s College, and as such had been closely associated with John Jones Search of the records shows that Middleton had suffered for some time from obstruction of the pylorus, of which affection he finally died in 1781

Since it is definitely stated that these operations upon dogs had been performed two years previously, in 1779, it will be observed that this work of John Jones antedates by almost a century the famous experiments of Gussenbauer and Von Winiwarter in Billroth's clinic, first performed in 1876, to which priority has heretofore been given It should be stated, in justice to them, that reference to Merrem's paper is made in their report It is interesting to speculate as to just how far John Jones, in his pioneer experiments on pylorectomy in dogs, was influenced by the teaching of John Hunter, whose disciple he was

Jones first began his medical studies under Dr Thomas Cadwallader of Philadelphia He then went to London and attended courses with William Hunter, McKenzie, and others, and at St Bartholomew s under Pott Afterwards he went to France, where he obtained his M D at the University of Rheims Later he visited Paris, Leyden and finally Edinburgh He later revisited London and renewed his friendship with Mr Pott and Dr Hunter, and was in attendance also upon the lectures of John Hunter His influence throughout was largely exerted toward the simplification of methods in surgery, undoubtedly the result of the teaching of Pott and Hunter This was especially evident in his work on wounds and fractures, a text-book widely used for a time John Jones was one of the outstanding figures in the early history of surgery in America, and the impress that he left upon it was deep and lasting

Vascular Surgery

Surgery of the vascular system, so intimately associated with the name of Hunter, early reached a high state of development in the colonies It was, of course, largely limited to ligation of the great arteries Among the early American surgeons noted for their successful work in this respect may be mentioned Valentine Mott, Wright Post, Rogers, Twichell, Gibson, and many others Indeed the Hunterian influence in this branch of surgery, thus early so pronounced, may be truly said to have continued unabated down to the present day through the original and important contributions of the late Prof Halsted and Rudolph Matas of New Orleans Lack of time prevents more than a brief reference to the first two named

Wright Post, after preliminary study in New York, went to London in 1784 Here he spent two and a half years He also made several subsequent visits There he attended the well-known clinics, Hunter's among the number Immediately upon his return to New York he began a course of anatomical and surgical lectures Later he became professor of surgery in Columbia College He acquired great reputation as an operative surgeon. His chief title to fame perhaps rests upon the remarkable success achieved by him in the ligation of large arteries He first, in America, ligated, and that successfully, the femoral artery after the manner of Hunter He was the first surgeon to tie the common carotid with success also the subclavian artery in its third portion He was one of the great exemplars in America of the principles laid down by John Hunter in the surgery of the arterial system

Valentine Mott took his medical degree in Columbia University in 1803 He then went to London where he became a pupil of Sir Astley Cooper, and through him, and like him, undoubtedly influenced by Hunter, he later achieved great fame from his extensive work in vascular surgery He also spent some time in Edinburgh under John Bell On his return to New York, true to his teachings, he began a course of private lectures on surgery which led to his appointment as lecturer and later, professor of surgery in Columbia He continued lecturing for 56 years—an extraordinary record His lectures were noted for their simplicity and the systematic way in which he dealt with his subjects Like Hunter's, they dealt largely with fact and little with theory Perhaps more than any other American surgical teacher he impressed upon his students the great importance of their work in anatomy and continued dissection As an operating surgeon, he showed great skill The particular operation which made his reputation upon both sides of the Atlantic was the ligation, in May, 1818, of the innominate artery Besides the innominate, says Billings, "Mott tied the subclavian eight times, the carotids 53 times, the common iliac once, the external iliac six times, the internal twice, the femoral 57 times, the popliteal 10 times, in all 139 ligations of the great vessels for aneurysm " A most extraordinary record, especially when one considers that the bulk of his work was done in the pre-anæsthetic era, and all of it in the pre-Listerian period Mott's accomplishments were not alone in the line of vascular surgery He did excellent work in bone and joint surgery, lithotomy and plastic work, especially operations for hare-lip His is one of the outstanding names in American surgery

McDowell's Ovariotomy

This list of early American exponents of Hunter's teachings would not be complete without at least a passing reference to one whose title to fame rests, perhaps, upon a single contribution

Ephraim McDowell had a very rudimentary education under Dr Humphries, a graduate of Edinburgh Through his influence McDowell went abroad and studied for two years in that University, where he came under the influence of John Bell, who made a deep and lasting impression upon him He spent a short time in London, attending the chief hospitals and clinics He then returned to his native country, and moving West, became one of the pioneer surgeons in that as yet undeveloped region In 1809 he performed the celebrated operation for the removal of an ovarian tumour, which constitutes his chief title to fame He later reported a series of five similar cases with four recoveries McDowell had difficulty in getting his first report published, as those to whom he submitted it refused to believe that an unknown backwoods doctor could accomplish anything like that It was finally accepted by the *Eclectic Repertory* of Philadelphia and appeared in that journal in 1817, but attracted very little attention—so little, in fact, that Nathan Smith knew nothing about it in 1821, when he reported his first case of ovariotomy as something new It was not until the account sent by McDowell to his old preceptor John Bell of Edinburgh, and which because of his death, did not reach him, but fell into the hands of Mr Lizars, an Edinburgh surgeon, and was published by him in the *Edinburgh Medical and Surgical Journal* in 1824, that McDowell received the recognition and credit due him He was an excellent anatomist, and gave courses in practical anatomy He was also a great lithotomist He had this peculiarity—he always preferred to operate on Sunday morning, saying that he liked to have the benefit of the prayers of the church

The Hunterian Tradition.

J J. Mumford, in his interesting work entitled, "Surgical Memoirs," in calling attention to the fact "that the best early American surgery grew out of English surgery, with John Hunter as its prophet," very aptly and justly divides American surgery into three eras, the first of which he calls the "Hunterian Era" The honoured names of those first surgeons, who drew their inspiration from John Hunter and whose accomplishments brought credit to their native country, are, as we have seen, William Shippen, jun, John Jones, Philip Syng Physick, Caspar Wistar, Wright Post, Valentine Mott, Ephraim McDowell, John Warren, John Collins Warren, and Nathan Smith That every one of these men—those who came directly under the personal influence of John Hunter as well as those who obtained their training secondhand, as it were, from his pupils—bear his marked impress and show it most emphatically in the open-mindedness, the honesty of purpose, and the zeal after truth which characterised their work, I have attempted to make clear That this influence has been further broadcast throughout the United States through the teachings of their pupils, and is active, even down to the present day, is apparent to the most casual observer

I have touched upon but a few of the more important results of John Hunter's teaching and influence upon early American surgery That he did, through his students, wield a commanding influence over medicine in general, the founding of medical schools and hospitals, and the collection of anatomical and pathological specimens is a matter of history But his greatest contribution, perhaps, was the emphasis which he placed in his teaching upon the correct use of one's faculties, careful observation, the collection of data, inductive reasoning, experiment, and the disregard *of tradition This is the legacy* that he has left to enrich the entire surgical world Since his time various other influences have been felt, have left their impress, and been succeeded in turn by others, the French, then the Austrian led by Billroth, and, lastly, the German and the Swiss led by Kocher. But none has been more profound and lasting than that inaugurated by John Hunter

Medical thought and action may be influenced in many ways and through various channels The magnetism of some compelling personality in medicine or surgery may have such a dynamic effect upon his associates and contemporaries as to affect profoundly their entire professional outlook Such an influence, not apt to be more than local, possibly national, is not lasting, nor is it readily transmitted, and it begins to wane as soon as the personality passes off the stage

Another great teacher arises, he may or may not have a personality, but he has something else He it is who discovers underlying principles and enunciates them for all time Whether or not such an one lives or dies, his influence continues, recorded and perpetuated in the lives and work and thought of his pupils, and those who come after Such a genius was John Hunter The principles that he, by dint of ceaseless labour, close observation, sound reasoning and carefully conducted experiment, worked out and finally promulgated are just as true and just as binding to-day as when first announced by him This is why he has remained such a power in the world of scientific surgery, and why, after the lapse of over a century, we do well to review again what he has wrought, to appreciate anew the value of his contributions to the surgery to-day, and to give honour to whom honour is due

Note—In the preparation of this address I wish to make due acknowledgment of invaluable assistance received from many sources Besides those authors named in the text, free use has been made of the work of numerous other medical writers and historians, chiefly that of Toner, Williams, Thatcher, Packard, and Garrison, and addresses and other material from various sources both published and unpublished

THE BLIND IN SCOTLAND

THE Third Report of the Scottish Advisory Committee on the Welfare of the Blind states that there are 6639 blind persons in Scotland on the Central Register kept by the Board of Health, which is an increase of 585 since the issue of the last report in 1924 The Committee explains that this increase is probably mainly due to the greater interest taken in the case of the blind since Government grants were provided for voluntary agencies and responsibility was placed on local authorities Of the total number of registered blind persons, 359 are under 16 years of age, and 2835 are between the ages of 50 and 70 This latter group are eligible in respect of age for the blind pension, and the Committee estimates that 2000 are now in receipt of the pension There has been a gratifying decrease in the number of blind children both under 5 years of age and between the ages of 5 and 16 Employment is found in institutions for 925 blind persons, an increase of nearly 200 in the past two years 4164, or approximately 62 7 of the total number of registered blind in Scotland are unemployable The sum of £83,902 has been paid by the State in the past seven years towards the maintenance of the services provided by voluntary agencies for the welfare of the blind in Scotland

The report makes recommendations on various subjects, including technical training and marriage The Committee states that it is not satisfied that a total of 288 (or 43 4 per 1000) blind persons either certified or certifiable as mental defectives by any means represents the true position. It is also of opinion that "mentally defective blind children, unless of low grade, could be better dealt with and educated in schools for the blind among pupils of a higher grade of intelligence than themselves than in certified institutions for mental defectives"

Copies of the report may be had from H.M. Stationery Office, 120, George-street, Edinburgh (Price 7*d*, post free)

A PROFESSOR'S FAIRY TALES

Her Majesty the Queen has accepted the first copy of a limited Presentation Edition of "The Scarecrow and other Fairy Tales," by Dr Leonard Hill, F R S, numbered and signed by the author A copy was also accepted by the Queen of the Belgians during her recent visit to the National Institute for Medical Research, when, at Her Majesty's request, it was specially inscribed by the author "To Queen Elizabeth from Leonard Hill" The fairy tales were printed by the author at the request of his friends on the occasion of his sixtieth birthday, and a limited edition will be published shortly by the Actinic Press, Ltd

SPECIAL LECTURES AT MEDICAL SCHOOLS

IT has been brought to the notice of the Fellowship of Medicine that certain provincial medical schools and societies wish to supplement their ordinary programmes by inviting teachers connected with the Fellowship to give special lectures The Fellowship is prepared to accede to any such request, and in order that definite arrangements can be made would be glad to hear from those provincial schools which are desirous of procuring such lecturers

Physique of Policemen—With reference to a paragraph under this heading which appeared in THE LANCET of Feb 12th, the chief constable of Leeds informs us that the actual daily percentage of sickness for the whole of the Leeds City Police Force during the year 1925 was 3 27 The average number of days absence in respect of each man off duty owing to sickness during this period was 19.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED FEB 12TH, 1927

Notifications—The following cases of infectious disease were notified during the week—Small-pox, 479 (last week 547), scarlet fever, 1281, diphtheria, 900, enteric fever, 22, pneumonia, 3192 (last week 3198), puerperal fever, 51, puerperal pyrexia, 136, cerebro-spinal fever, 17, acute poliomyelitis, 10, encephalitis lethargica, 33, dysentery, 4; and ophthalmia neonatorum, 126 No case of cholera, plague, typhus fever, or polio-encephalitis was notified during the week

No further case of small-pox was notified from Portsmouth C B or from Essex, whilst two more were notified from Stockport C B The remaining cases were distributed, as last week, among the following counties Derbyshire, 23, Durham, 289, Lancashire, 3, Northumberland, 11, Nottinghamshire, 6, Yorkshire, 145

Deaths—A death from small-pox was reported from South Shields In the aggregate of great towns, including London, there was 1 (1) death from enteric fever, 47 (0) from measles, 6 (1) from scarlet fever, 129 (34) from whooping-cough, 46 (16) from diphtheria, 28 (3) from diarrhœa and enteritis under 2 years, and 759 (159) from influenza The figures in parentheses are those for London itself The influenzal deaths for the last six weeks have thus been 173, 326, 470, 725. 818, 759, while 990 is the figure notified for the week ended Feb 19th, the figure for London being 128

Hunterian Oration

ON THE VALUE OF
MODERN METHODS OF INVESTIGATION IN THE DIAGNOSIS AND TREATMENT OF
HÆMATURIA.

Delivered before the Hunterian Society on Feb. 28th, 1927,

BY W. GIRLING BALL, F.R.C.S. ENG.
PRESIDENT OF UROLOGICAL SECTION, ROYAL SOCIETY OF MEDICINE; SURGEON WITH CHARGE OF OUT-PATIENTS, ST. BARTHOLOMEW'S HOSPITAL.

[Mr. Girling Ball began his lecture with a brief historical review of the methods used in the diagnosis and treatment of urinary disorders. For many centuries, he said, these have been dealt with surgically. A method of removing vesical calculi was described by Celsus as in use amongst the Greeks and Romans. It became known as "cutting upon the gripe or with the lesser apparatus" and remained in vogue until early in the sixteenth century when Johannes de Romanis, of Cremona, is said to have devised the method of "cutting upon the staff or with the greater apparatus." At an early period a distinction was made between urogenital and other surgeons, and in 1634 a dispute arose at St. Thomas's Hospital about the appointment of a certain Mr. Cleeve, "who had been recommended to them for his skill in cutting for stones, in place of a certain Mr. Moby, who showed a singular lack of the same, in addition to the fact that he was rebellious against the King." The art was commonly practised by a special class of "cutters," the cases apparently only being dealt with by a surgeon when "there was money in it." John Douglas and Cheselden (1719) laid the foundation of the modern operation of suprapubic lithotomy known as the "high operation for the stone." Other landmarks in urogenital surgery were the first transperitoneal nephrectomy by Walcott (1871), after which the patient died on the fifteenth day, and the first successful lumbar nephrectomy in this country by Durham (1872). The date of the first removal of stone from the kidney is uncertain, but Dominique Marchettis performed a two-stage operation for this purpose in 1633, extracting the stone but leaving a permanent fistula. To Henry Morris (1881) is attributed the modern procedure. Litholapaxy was first done by Bigelow (1878); lithotrites were used before his time, but no artificial means of evacuating the fragments had been devised. In 1635 Covillard removed what is described as a growth—possibly part of the prostate—from the bladder. To Albarran must be given credit for surgery of vesical tumours, whilst the first tunnelling operation for prostatic enlargement was done by Hunter (1805). Mr Ball concluded his historical summary by speaking of the remarkable change in urogenital surgery which followed the discovery of X rays, the introduction of cystoscopy by Nitze, and the use of chemical and bacteriological methods. With modern equipment it is now possible in most cases to arrive at an almost accurate diagnosis of lesions of the urinary tract, and the symptom of hæmaturia affords an excellent example of the value of the methods now available. The lecturer continued as follows:—]

HÆMATURIA AS A SYMPTOM.

Fortunately, hæmaturia is a symptom which, although often neglected by the patient, is usually of sufficient prominence to lead him to call for medical aid. Unfortunately, however, he is not always stimulated by his adviser to undergo thorough investigation, but is treated on expectant lines in order to allay the hæmorrhage instead of discovering its cause.

This may be due to several reasons; one commonly met with is that the bleeding has ceased when he applies for advice to his doctor, who may not sufficiently appreciate that as a symptom it is invariably an indication of the existence of some serious pathological condition. This attitude can be partially understood, especially if the hæmaturia is limited to a single act of micturition, for it is not generally recognised that considerable information can be acquired in the period after the bleeding has ceased. Again, it may be difficult to convince the patient that a single bleeding demands an elaborate examination; but this is so common a feature of cases of intermittent hæmaturia, often of the painless type—due, shall we say, to a growth in the bladder—that an investigation should be insisted upon, thereby avoiding the loss of much valuable time in waiting for a subsequent attack.

Yet again, to take another example, if the hæmaturia still persists it too often happens that a full examination is postponed until after its subsidence, on the supposition that it cannot be carried out during this period. This, of course, is quite a fallacy; for the ideal period for defining the origin of the blood is while the bleeding continues. These are instances of an error in attitude which are quite commonly met with, and it is an endeavour to correct this attitude that has led me to choose this subject for my address. The advantage to be gained by adopting the use of adjuvant methods of investigation cannot be too strongly emphasised: the waiting for obvious physical signs, so often conspicuous by their absence in cases of hæmaturia, is only to be condemned. It is not my intention to attempt to deal with the diagnosis of hæmaturia, which may be a symptom of almost any disease of the urinary tract, but rather to detail the method of approaching a case of which this symptom is a prominent feature, illustrating these methods by their application to special diseases.

SOURCE OF THE BLOOD

Hæmaturia varies in degree and within very wide limits: the bleeding may be so small in quantity as to be only recognised by the microscope, or it may be so profuse as to give the urine a bright-red or a smoky appearance, with a heavy brown deposit on standing. It is obviously necessary, in the first place, to prove by microscopic examination that the discoloration is due to blood and not to some other pigment. Having proven that blood is present, and that one is not merely dealing with a case of hæmoglobinuria, &c., the initial effort must be directed to discovering the site of its origin. It is no doubt within the memory of most of us that the distinction between a renal hæmorrhage and one originating in the bladder was, and is even now, by some arrived at by the appearance of the urine passed; the dark coloration and intermixture of the blood with the urine in the one case, and its bright colour, often only at the end of micturition in the other, are often drawn attention to. A rough-and-ready method of distinction it may be, but it should not be recognised as a means of differentiating the site of a lesion, otherwise a wrong conclusion will often be drawn. Even a three-glass test is often inaccurate. The sudden clearance of bleeding after washing out the bladder suggests a renal origin, whereas a persistence of it indicates a vesical lesion. The passage of clots of blood in the form of ureteric casts must be suggestive of a renal bleeding. Examination for the presence of some general constitutional disease must naturally receive adequate attention before concluding that the hæmorrhage is the result of a local lesion. Evidence of renal inefficiency, the presence of arterial disease, cardiac lesions, hæmophilia, scurvy, &c., may be found; but here, again, it must be remembered that evidence of the existence of such general conditions does not necessarily mean that they are responsible for the hæmaturia. This point could not be better illustrated than by the following record:—

Some years ago I was asked to cystoscope a man of [illegible] years of age who had for many years been treated by his physician for chronic renal disease The many attacks of painless hæmaturia which he experienced were regarded as being the result of this condition One day, however, he had a particularly severe hæmorrhage, which led his doctor to ask for a cystoscopic examination, which demonstrated the presence of a large villous tumour of the bladder, the removal of which caused the bleeding to cease

True, it is, that this man had chronic renal disease, but the hæmaturia was due to the growth.

In diseases of the urinary tract itself, localising symptoms frequently indicate the site of origin of the bleeding, but even such must be accepted only with the greatest discrimination, for although they suggest that the bladder is the site of the disease, the kidney may, in reality, be the site of its primary focus, the bladder lesion being only secondary to it, and vice versa A case recently under my care illustrates this point admirably :—

A man, aged 23 had all the symptoms of a vesical calculus, with great pain relieved by rest His frequent micturition was reduced from 18–6 acts during the 24 hours by putting him to bed The bright red blood which he passed disappeared immediately from the urine A cystoscopy, however, demonstrated a tuberculous ulceration around the ureteric orifice and the removal of the kidney on the affected side of the bladder confirmed the diagnosis of renal tuberculosis This man had never had a symptom which would localise his disease to the kidney, which was an old-standing condition

Let it not be thought that a record of the symptoms is to be discarded as useless ; far be it from me to make any such suggestion, for it is obvious that a great deal of information can be gained by the acquisition of an accurate history relative to the type of hæmaturia, its persistence, its frequency, its amount, and its relation to other symptoms The mode of onset of the hæmaturia is often suggestive of its cause ; its accompaniment with pyuria and persistently increased frequency of micturition points to tuberculosis , a sudden profuse painless hæmaturia indicates the presence of a growth , the association with the symptoms of pain of a certain definite type will often point to the site of the lesion, as in a case of calculus, and so forth These symptoms give indications, but they by no means enable us to be sure of the site of origin of the bleeding

THE NEED FOR IMMEDIATE INVESTIGATION

These remarks will serve to illustrate the necessity of defining as accurately as possible the site of the bleeding focus Let me go one step further. A physical examination of the urinary tract may define the presence of a renal tumour, for which the presence of a growth or some inflammatory disease may be responsible A nodule in the testicle may suggest the presence of tuberculosis disease of the urinary tract ; an enlargement of the prostate, discovered by rectal examination, may indicate an innocent or malignant growth of that organ , but many of these findings are only obvious in the later stages of the disease of which they are the evidence Surely, an attempt should be made to arrive at a diagnosis ere a tumour of the kidney is palpable, or a secondary focus from a tuberculous kidney appears in the testicle, and the opportunity for doing so is often available Hæmaturia is often the only sign and the first evidence of these conditions and may precede the major manifestations by many weeks or months It is to this period that we should direct our attention, and then the only means of obtaining the information required is by the use of the cystoscope

Cystoscopy during Hæmorrhage.

As already stated, it is very disappointing in practice to find that the impression still prevails that a cystoscopic examination cannot be carried out during the period of bleeding No doubt this results from the recollection of the experiences of those who remember the time when the performance of cystoscopy required the preliminary cleansing of the bladder through a catheter, thereby allowing an interval for the medium introduced into the bladder to become sufficiently turbid to prevent a proper view being obtained , but with the use of the modern catheterising cystoscope this difficulty is avoided Now, it is obviously a material advantage to make the examination during the period of bleeding , indeed, the loss of an opportunity of doing this may be of exceeding importance in prognosis If the source of hæmorrhage is in the bladder, the technique available enables one almost invariably to obtain a satisfactory view of the condition present, but even if this is not possible at the first investigation, it is at least presumptive evidence that the lesion is in the bladder and can be left for further investigation during a quiescent period, or dealt with as circumstances demand If, on the other hand, the blood is coming from one or other ureter, thereby proving that it or the kidney is the source of the hæmorrhage, the bladder can always be sufficiently cleansed to recognise this fact Unfortunately, the circumstances too often are not so favourable, for the case may only come under observation during the period after or between two attacks of hæmaturia It is true that bladder lesions, such as papillomata, carcinomata, tuberculous ulcerations, or enlargements of the prostate, can, during this period, still be readily diagnosed, and in the case of tuberculosis, or other chronic infections of the kidney, the recognition of characteristic lesions collected around one ureteric orifice will indicate which kidney is the original site of the disease Abnormal appearances of a ureteric orifice are useful guides of renal disease. But the real difficulty lies in defining the site of the lesion in the absence of hæmaturia or of an indicator in the bladder The natural tendency is to wait for a recurrence of the bleeding, especially if the ordinary physical signs give no indication of the presence of disease, but this is an incorrect attitude to adopt

Let us consider the case in which at the moment of investigation the urine shows no abnormality, allowing that the same procedure would be adopted if the circumstances permitted, during a period of bleeding.

PRELIMINARY RADIOGRAPHY

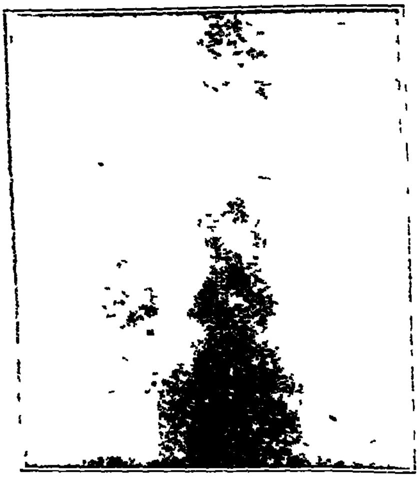
The assistance of the radiographer is first sought ; even in the absence of other symptoms, the exclusion or demonstration of a calculus, or any other abnormality capable of casting a shadow is essential Attention need hardly be drawn to the necessity of a proper preliminary treatment of the patient before radiographic examinations are made, especially with reference to the cleansing of the bowel , by this means shadows which may be caused by foreign bodies in that tract are excluded The close cooperation between the surgeon and the radiographer is of primary importance

Photographs of the whole of the urinary tract should be taken, no matter which portion is suggested by the symptoms as being the site of the lesion The identification of a true renal, ureteric, or vesical calculus is, as a rule, beyond doubt , but occasionally difficulty arises and misinterpretation of the findings results in improper methods of treatment It often happens, for example, that shadows are demonstrated whose mere association with an attack of hæmaturia suggests the presence of a calculus, whereas the physical characters of the shadow do not fit in with those usually expected of it To avoid a misinterpretation of these appearances the greatest care must be taken, and it is here that the cooperation mentioned is of the greatest value Take the case of a patient who has a single large shadow in the right hypochondrium, demonstrated in a picture taken in the antero-posterior axis as lying exactly over the renal area, but which has the ringed outline so characteristic of a gall-stone Gall-stones of this type can usually be recognised, but their association with hæmaturia naturally biases an opinion in favour of a renal calculus I have actually seen such a case in which the surgeon explored for a renal stone on this misapprehension, and only the failure to find it led him to explore the gall-bladder and remove a gall-stone

The taking of pictures in a lateral combined with the antero-posterior axis will avoid mistakes of this kind by showing the relationship of the shadow to the abdominal wall, if not actually to the kidney itself; or pictures may be taken stereoscopically. In the case of large stones, if they can be seen, the screen examination will serve the same purpose, and the mobility of the shadow, in relation to the viscus suspected of containing it, defined.

Foreign material in the appendix and calcareous lymphatic glands lying along the course of the ureter or in the mesentery are frequent causes of error, although, as a rule, their radiographic appearances are usually sufficiently characteristic to distinguish them. These shadows are usually small, but may be considerable in size, and even simulate the appearances of calculi. (Fig. 1.) They are usually situated in the right iliac fossa, but may be found in almost any position in the abdomen, even as high as the renal area. From their physical characters, radiography may be quite sufficient to define their nature. Apart from their appearance, manipulation of the abdomen while the patient is being X rayed, or even a change of position, may give a degree of mobility to the shadow which would be quite impossible with a calculus within the urinary passages. This finding naturally conduces to setting aside the diagnosis that the calcareous gland is responsible for the hæmaturia. This may be true, but on the other hand, it must be remembered that although this particular gland may not be related to the ureter, there may be some actively inflamed glands not showing calcareous degeneration more intimately attached to it.

FIG. 1.



Mass of tuberculous glands shown by X rays associated with hæmaturia and resembling calculi

Again, pelvic phleboliths are commonly demonstrated by the radiographer. A single shadow associated with hæmaturia naturally suggests the presence of a stone; where there are many such shadows, one of them can often be picked out as having different characters from the rest, and be regarded as a stone fragment.

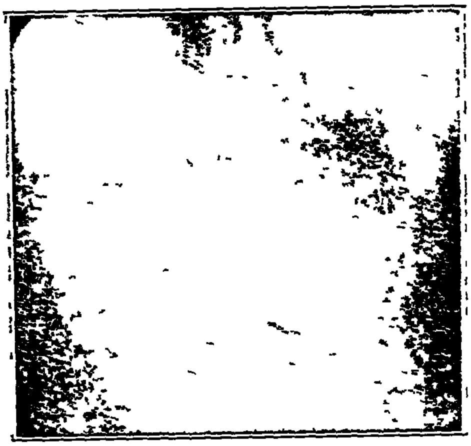
It is thus evident that in a case of hæmaturia ordinary radiographic methods may be sufficient; but on the other hand they may fail to give a certain diagnosis of a calculus. Moreover they may fail to demonstrate any shadow at all. Under both these circumstances further investigations are required unless another attack of hæmaturia is awaited, which, as already stated, if possible is to be avoided.

DIFFERENTIAL DIAGNOSIS OF RENAL CALCULI.

Let us first take the case in which the shadow is demonstrated but of the nature of which there is doubt. The simplest addition to the radiographic investigation consists in the passage of a ureteric bougie composed of material opaque to the X rays. (Fig. 2.) This will define the connexion of the shadow with the course of the ureter or the renal pelvis, especially if a stereoscopic picture is taken.

The shadow of a stone within the lumen of the ureter may be of sufficient size to block the passage of the bougie altogether, and all doubt is dissolved. But this may not be the case: the bougie may pass and unless the shadow is displaced—thereby indicating the presence of a stone—this will not necessarily exclude a calcareous gland adherent to the walls of the ureter. A gland, by its adhesion, may so alter the position of the ureter and prevent the passage of a bougie, but this is not common. Under these circumstances some opaque fluid, such as sodium bromide, is passed into the ureter through a ureteric catheter, causing distension of it and of the renal pelvis. (Fig. 3.) This will mask a shadow in the renal pelvis or within the ureter; moreover, it will demonstrate any secondary changes of either, such as stricture of the former or dilatation of the latter. Yet, again, it will clearly demonstrate the external relationship of any shadow caused by lesions outside the tract: furthermore, its distance from, or close attachment to, the ureter will indicate the possibility of its being the cause of the hæmaturia.

FIG. 2.



Relationship of opaque bougie to prostatic calculus.

FIG. 3

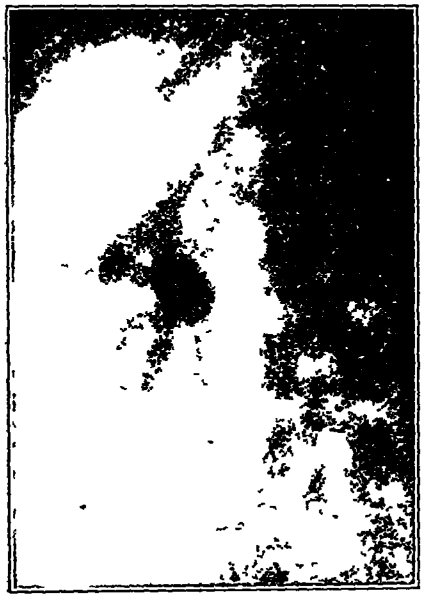
Pyelogram of normal pelvis showing external relationship of shadow of tuberculous glands reported on as renal calculi owing to association with typical symptoms of stone

These illustrations will suffice to indicate the use of those methods when a radiograph has demonstrated a shadow.

Calculi Translucent to X Rays.

Now let us turn to the case in which a stone is suspected as being the cause of the hæmaturia but in which it is not demonstrated by radiography. This is an uncommon event, as with the exception of the rare stone of pure uric acid formation calculi are usually demonstrable; cases are, however, met with from time to time in which the calculus [illegible] present, has not been discovered even after repeated radiographic examinations Renal stones lie within the pelvis or in one of its calyces, and quite early in the course of the symptoms, for which they are responsible, cause a distension of the calyces without altering the shape of the pelvis, except by their own shape; this ballooning of the calyces is a characteristic feature readily demonstrated by a pyelogram (Fig 4) I have on at least two occasions removed a renal stone, the existence of which was only recognised by this appearance

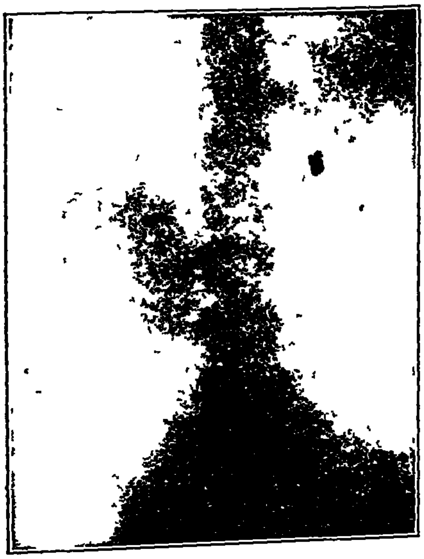
FIG 4.



Typical pyelogram of early calculus hydronephrosis

This observation is of some importance, for the pyelographic shadow, due to an obstruction of the ureter or renal pelvis by some extra tract lesion, demonstrates a distension of the renal pelvis without, in the early stages, affecting the calyces This deformity is associated with such conditions as movable kidney, congenital hydronephrosis, and hydronephrosis associated with abnormal renal vessels (Fig 5), and even strictures or deformities of the ureter due to the adhesion of calcareous lymphatic glands or adherent appendices The symptoms produced by these conditions may very closely simulate those of a calculus, even to the production of an attack of hæmaturia, presumably due to congestion of the renal tissue beneath the pelvic mucosa Thus it is seen that a pyelographic examination may be, apart from an exploratory operation, the only means of distinguishing such conditions

FIG 5.



Typical early hydronephrosis associated with abnormal renal artery

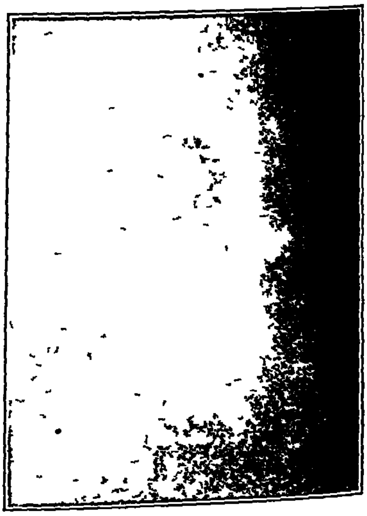
Before leaving the question of stone, it is desirable to emphasise the fact that where multiple calculi are present a radiograph does not necessarily show up the whole number present I myself have removed 13 stones from a renal pelvis which showed the existence of 11 on radiographic examination and subsequently, after nephrolithotomy, demonstrated the presence of a further 12 Misinterpretation of this kind has to be looked for and may be unavoidable A distension of the renal pelvis with fluid, which need not for this purpose be opaque to X rays, may break up a collected mass of small calculi and demonstrate their multiplicity and by rearrangement bring into view many that were not previously seen.

This examination was used with some satisfaction on one occasion when multiple shadows shown by the X rays were thought to be due to calcareous glands Distension of the renal pelvis with sodium bromide showed a typical calculus hydronephrosis When the fluid was run off a second picture showed that the fluid had split up the shadows into still further fragments, thereby confirming the diagnosis.

NEOPLASMS OF THE KIDNEY.

Hæmaturia is often the only symptom and sign of renal growths The bleeding, in contra-distinction to the conditions already mentioned, is often sufficiently profuse and persistent to cause a rapid onset of a secondary anæmia This is suggestive of the presence of a growth especially if the bleeding is seen to arise from one ureteric orifice With large growths, and in the later stages, simple radiographic examinations may demonstrate a big kidney. In the absence of bleeding, however, the question naturally arises as to whether pyelography will enable us to recognise the presence of a growth in its early stages Sometimes a diagnosis can be accurately made by this means; it may be necessary to investigate both kidneys if there are no other symptoms suggesting which is at fault Growths of the renal parenchyma have, even in the early stage, a tendency to bulge into the renal pelvis rather than to extrude from the surface of the kidney. In this way they splay out and elongate the calyces in a characteristic Y-shaped formation (Fig 6)

FIG 6



Typical pyelogram associated with growth of the renal parenchyma.

In the later stages growths of the renal pelvis, which are rarely seen, likewise tend to fill up the pelvis and thus prevent the introduction of any fluid into its cavity. In the earlier stages an irregular filling defect is suggestive of a papilliferous growth of that structure Sometimes such growths are associated with papillomatous growths in the bladder, which can be observed cystoscopically A unilateral renal hæmaturia seen to be coming from a ureteric orifice, in the neighbourhood of which is a villous tumour, should suggest that this is secondary to a similar condition in the pelvis of the kidney.

INFECTIONS OF THE URINARY TRACT

So far we have discussed cases in which, apart from containing blood, the urine shows no abnormality and during periods of intermission there has been no unusual constituent to suggest the presence of a lesion There are other cases, however in which, with the disappearance of the bleeding, abnormal substances remain Pyuria for example, may be found This, obviously, may be due to any of the conditions already described, and the same methods of investigation are called for, but in addition, the bacteriologist becomes a powerful ally; the isolation of the bacteria of infection will often give important information

In the first place, the nature of the micro-organism may be indicative of the type of lesion in the kidney: it may indicate that it is secondary to a primary focus in some other part of the body, the existence of which was hitherto unsuspected. The finding of the *Staphylococcus pyogenes aureus*, for example, may be evidence of an infarct in the kidney secondary to a boil on the neck; whilst typhoid infections of the urinary tract are not uncommon complications of enteric fever On the other hand, by its specific nature in the case of a primary lesion of the kidney, it may indicate the exact nature of that lesion The finding of the tubercle bacillus after one or more examinations or after inoculation of an animal, with a centrifugalised deposit of the urine, is an illustration of this type; even if the bacilli are not found, a sterile urine should lead to a suspicion of their presence.

Tuberculosis

Such findings as these are important but the problem of discovering the source of the bacteria is the same In this connexion tuberculosis affords an excellent example A bilateral disease is not amenable to surgical treatment, a unilateral infection is a satisfactory condition to deal with Is it possible, therefore, to differentiate between these two? A cystoscopic examination is the most useful aid in our possession, as it may demonstrate areas of congestion, tubercles, ulcers œdema, dragging upwards of the orifice or rigidity of the margins of one ureter, thus indicating which kidney is the site of the primary focus of infection.

Interpretation of the view obtained may be difficult, for if a considerable area of the bladder is involved, both ureteric orifices may be included in the tuberculous cystitis This naturally leads to the inference that the disease is involving both kidneys It must be remembered however, that this is not necessarily the case A period of rest may so alter the appearance seen that a re-examination at a later date may show that a suspected bilateral infection is really limited to one kidney The finding of these lesions is of the greatest assistance in diagnosis, but they may not be present The occasion sometimes arises when the bacilli are found in the urine and there is no indication which kidney is involved. There may be no localising signs indicating which is the seat of disease, for quite commonly a kidney may be considerably destroyed by tuberculosis without giving any evidence that it is affected; this is supported by the frequency with which a case of tuberculous nephritis fails to come under observation prior to the onset of vesical symptoms Catheterisation of the ureters may give the necessary proof; the presence of purulent sterile urine collected from one side and not from the other may serve as an indicator; again, by a lucky chance, bacilli may be isolated from one such specimen and not from the other

Radiography may demonstrate caseous or calcareous deposits Pyelography may be tried, although it is not a particularly desirable condition in which to use this method of investigation: the rupture of a cortical abscess into the renal pelvis may demonstrate an irregularly shaped calyx or an irregular margin to the renal pelvis which may be sufficiently suggestive. If these investigations fail, the use of the tests of renal function may be applied to each kidney. Apart however from the ordinary chemical and bacteriological investigations, as a means of differentiating the function of the two kidneys little value can be attached to these findings The dye test it is true may indicate from time to time the presence of a gross lesion in one kidney, but as a means of diagnosis its value is uncertain It is in this attitude that they must be utilised In the absence of these findings, as a rule it is necessary to await events The diagnosis of the site of a tuberculous focus in the urinary tract, in the absence of macroscopic lesions, which can be seen, may thus be very difficult.

Non-tuberculous Infection of the Kidney

Lastly, let me add a few remarks with regard to the diagnosis of renal infections other than tuberculosis Acute infections of the urinary tract, apart from those associated with other pathological conditions are so commonly met with that the symptoms they produce enable their easy recognition. Little, however, is known of their exact origin. Sometimes, especially in severe acute infections there is evidence of involvement of the kidney; in these cases, the vesical symptoms are the most evident; and yet again there may be few symptoms, except fever, the presence of a urinary infection only being discovered by an examination of the urine.

It is generally presumed that these infections are of hæmatogenous origin the initial foci being found in the bowel, the tonsil, the air passages or elsewhere. A complete recovery from such an infection is not uncommonly seen, but there is a tendency for it to persist or become recurrent, which naturally raises the question whether there is not some factor in the urinary tract itself which predisposes to these sequelæ

A bilateral infection is presumably frank evidence of a generalised infection. Before assuming that it is of this nature however, it is necessary to demonstrate that there is no obstructive lesion below the entrance of the ureters into the bladder, either within the tract or in the pelvis—e g., an enlarged prostate, a urethral stricture, fibroids the pregnant uterus or inflamed tubes A unilateral infection, although it may be of like origin, might reasonably be expected to depend on some localising factor It is surprising how often it is possible to demonstrate the presence of some obstructive lesion by the methods of investigation already enumerated Obvious illustrations of these are the cases of early hydronephrosis associated with a movable kidney or an abnormal renal vessel.

This being so it is a necessary corollary that in such cases abnormalities should be sought for. In dealing with a case of urinary infection it is important to discover if possible, the presence of some associated factor within the tract itself, for it is difficult to believe that an infection can persist in a normal urinary tract This argument may be carried still further to prove that in some cases structures outside the tract—for example, the appendix and the large bowel—may involve it in the process of their diseases and cause the maintenance of an infection I have recently recorded a group of this type, included amongst which is the following case which serves as an excellent illustration of this point, and shows the necessity for the procedures here advocated in connexion with urinary infections:—

A woman aged 46, suffering from a sufficiently severe hæmaturia to cause a marked secondary anæmia and extending over a period of six weeks was passed through the ordinary methods of investigation with negative results, beyond the fact that the blood was seen to be derived from the right ureter A pyelogram demonstrated the presence of a considerable early hydronephrosis, the cause of which was not obvious, except, possibly, a kink at the uretero-pelvic junction The urine at this time was sterile. A lumbar exploration failed to demonstrate anything abnormal except the conditions above mentioned However, the hæmorrhage had been so severe that a nephrectomy was performed Imagine my chagrin to find that the hæmaturia persisted and did so until three months later when the patient returned with infected water and a typical attack of acute appendicitis With the removal of the appendix the hæmaturia and the infection ceased

This case serves to illustrate that one must not even be content to examine only the urinary passages, but must carry out investigations of those structures which lie in its neighbourhood

The routine procedure so commonly adopted in the treatment of urinary infections—namely, the institution of free diuresis, the use of urinary and alimentary antiseptics, and the introduction of vaccine-therapy—are, to my mind, to be deprecated until a thorough search for the presence of some factor predisposing to the incidence, the recurrence or the persistence of such infection has been sought for Of course, these investigations will from time to time fail to elucidate such a cause, which may remain undiscovered until some exploration is made or some incidental condition, such as occurred in this case, accidentally defines its presence, the finding of such a lesion may save our patients years of useless treatment

Essential or Idiopathic Hæmaturia.

There are many other causes of hæmaturia which might be discussed, but they need not be referred to here, as the mode on investigation is common to them all The aid of the cystoscopist, the radiographer, the pathologist and the chemist may all be necessary to our service, thereby demonstrating the necessity of good team work ; with this tract the results show how valuable this collaboration may be, and how far it is possible to be almost accurate in the diagnosis of a given case Still, even with all these means of diagnosis, there remains one group which must be mentioned, for which no cause for the bleeding is discoverable, to this the term "essential" or "idiopathic" hæmaturia is applied

This used to be a fairly common diagnosis, but owing to our better equipment it is fast disappearing, as some responsible cause can be defined in many cases which hitherto would have been so grouped ; one of the causes mentioned above was found after removal of the kidney, chronic nephritis was shown to be present in others, although clinically the patients showed no evidence of that condition. But still, occasionally, kidneys bleed and are removed which show no discoverable lesion even after the most careful microscopic investigation, and more surprising still, the source of the bleeding often is not found In some instances, minute nævi have been demonstrated of so small a size as to be missed by one trained observer and found by another, probably this is the explanation of others Practically, it is not possible to recognise such lesions before the removal of the kidney, nor will it be possible until some genius invents an instrument through which the interior of the pelvis can be observed

Improved Standard of Treatment

The introduction of all valuable methods of investigation must necessarily lead to an improvement in our methods of treatment It is indeed interesting to compare the ease and certainty with which a stone of the kidney can be demonstrated and removed by pyelotomy with the problematical finding of our forefathers, amongst whose equipment was found a knitting needle with which to prod the kidney tissue to demonstrate the existence of the calculus, to be followed by an incision through the so-called bloodless line, inevitably causing severe damage to the kidney, often serious hæmorrhage, and possibly a subsequent nephrectomy

It is now possible to demonstrate by pyelography the degree of damage of the renal tissue caused by the stone, so that the surgeon, prior to the operation, may know whether or not a nephrectomy will be required In the case of a very small stone, where he may mistrust his ability to find it, he can actually demonstrate by the same investigation the site of the calyx containing it The introduction of the tests for renal function in cases of enlargement of the prostate, thereby demonstrating the damage done to the renal tissues by obstruction, has led us to select only such cases for an immediate prostatectomy in which the function of the kidneys can reasonably be expected to withstand the serious effects of the operation and to deal with the remainder by a two-stage operation It has also taught us to be cautious in recognising the presence of two kidneys and to avoid the removal of the only or the only functioning kidney The demonstration of an early hydronephrosis has enabled us to carry out such procedures as will prevent the more complete destruction of the renal tissue which would otherwise have been inevitable, and the formation of those enormous cysts which might be mistaken for a similar lesion associated with the ovary. Pyelographic examinations have also enabled us to recognise the existence of a malignant growth of the kidney at a stage with a reasonable chance of complete eradication, which would otherwise not have been demonstrated except by an exploratory operation or by the finding of a large tumour beyond the hope of removal

These are some of the advantages in which the modern methods of diagnosis of genito-urinary conditions have led to more efficacious means of treatment ; but perhaps of still greater interest, certainly to the public, has been the introduction of methods of treatment by intravesical procedure, thereby avoiding cutting operations which are hated by man and lead to the loss of much valuable time, which is bound to be of an important consideration to the worker It needs only to mention the removal of vesical stones by lithotrity, the destruction of villous tumours of the bladder by fulguration, the encouragement of the expulsion of ureteric calculi by the passage of bougies or the introduction of oil and drugs through a ureteric catheter, the destruction of portions of the prostate by diathermy in cases not suitable for the major operation or where there is some special indication pointing out its advantage

Surely, the advances which have been made and those within such a short period of time would have been after the heart of the great master whose name this lecture commemorates

Hunterian Lecture

ON

RECENT ADVANCES IN

THE SURGERY OF HERNIA.

Delivered before the Royal College of Surgeons of England on Feb 16th, 1927,

By ERNEST M COWELL, D S O, M D Lond,
F R C S Eng,

HUNTERIAN PROFESSOR OF THE COLLEGE, SURGEON TO
CROYDON GENERAL HOSPITAL

The surgical history of hernia dates back to time immemorial, the subject being referred to in the earliest writings of our craft There have been three main periods, according to the method of operative treatment employed

1 *The Age of Herniotomy*, when the sac was excised and ligatured Celsus and Galen, in the first and second centuries A D, described and practised this procedure At this time hernia was thought to be due to a "rupture" of the peritoneum Paulus Aegineta, of Alexandria, in the seventh century A D, taught that the condition was not due to a sudden giving way of the peritoneum, but rather to a gradual distension and protuberance Itinerant herniotomists flourished in the middle ages, men who operated on patients in large numbers and then moved on to the next town

Pierre Franco and Ambroise Paré in the sixteenth century contributed to our knowledge of the condition In the seventeenth and eighteenth centuries, when the study of anatomy was being carried out by many skilful observers, several new types of hernia were described, and an extensive literature was compiled by such men as Littre, Petit, de Gimbernat, Richter, &c Early in the nineteenth century Scarpa in Italy and Sir Astley Cooper in this country published beautiful atlases of drawings of their hernial dissections.

With the advent of Lister's discoveries surgery received an immense impetus, and open operation became safer and more popular. Annandale in 1876 first operated on femoral hernia by the inguinal route. The number of herniotomy operations multiplied so that in 1884 Prof. Sir A. E. Barker was able to write a paper on 35 Operations for the Radical Cure of Inguinal Hernia by Original Methods.

2. *Second Period: Herniorrhaphy.*—The second period commenced with the description by Bassini (1890) and Halsted at about the same time, of a more elaborate procedure for the surgical cure of inguinal hernia. Many modifications and elaborations of these methods have since been described. Anterior and posterior imbrication of the external oblique aponeurosis (E. Wyllis Andrews, Edmund Andrews, Stetten and others), plication of the fascia transversalis (Pitzman), and other methods of reinforcing the coverings of the canal by suture are still popular, especially in America. In this group of herniorrhaphies may be included the filigree method of Bartlett, popularised in this country by Laurie McGavin. In this type of operation however, in spite of their complicated technique, the rate of recurrence has remained too high.

3. *Third Period: Hernioplasty.*—Kirschner in 1910 pointed out the fact that free fascial grafts could be successfully employed and he used the method in one case of inguinal hernia. Lewis, Dean, and Davis in 1911 and 1914 published similar observations. It was not till 1921, however, that Gallie and Lemesurier in Canada, reintroduced the subject. These authors employed strips of fascia lata from the thigh and used them to reinforce the weak posterior wall of the inguinal canal. Pedunculated strips of external oblique aponeurosis were used in a similar way by McArthur in 1901, McEachern, and also Adair in 1924, and Wainschenker (1923, published in 1925). In my own method pedunculated autogenous flaps of the external oblique aponeurosis are employed as will be shown later.

The results of hernioplasty are extraordinarily good. In the present series of 201 hernias no patient has been refused operation on account of age or general condition. Careful follow-up methods have so far revealed a single case of recurrence.

CLINICAL OUTLINES.

I do not propose to enter into an extended discussion of the signs and symptoms of hernia. In the earliest stages the patient complains of symptoms which are due to reflexes from the peritoneum concerned. Thus dyspepsia, epigastric uneasiness, umbilical pain or backache may be met with. Later the local bulging is noticed. The symptoms are usually slight in the case of femoral hernia. A pain which radiates down the inner side of the thigh should lead the observer to suspect an obturator hernia.

On examination of the hernial region swellings may appear, and lateral inspection will reveal whether the inguinal canal is filled or not. The relation of the swelling to the pubic spine must in all cases be accurately determined. Two early physical signs of inguinal hernia are given by Watson: (*a*) Cosens's sign, the alert rectus. The rectus muscle on the affected side is found to be tenser than on the other. (*b*) Watson's sign—painful subcutaneous ring. With the patient erect and head up, pressure over the external rings will cause complaint of pain on the weak side. Lastly, the grip or shutter action of the internal oblique and transversalis muscles should be determined, as pointed out by Sir Arthur Keith.

In the femoral variety of hernia the swelling first appears below Poupart's ligament external to the pubic spine, and thence may extend upwards over the ligament, downwards into the thigh, or outwards along Poupart's ligament.

ANATOMY.

In order to study the blood-supply of the hernial region and to determine the vascularity of the aponeurosis of the external oblique, block dissections were made, injected through the external iliac artery with lead oxide suspension, and then radiographed. In the resulting photograph (Fig. 1) it will be seen that the external oblique aponeurosis itself contains but very few blood-vessels. The fascia which was reflected from its surface and which lies curled up contains a fine network of nutrient vessels. This would at first sight appear to be an important point in the surgery of this region and an argument against cleaning the aponeurosis before commencing plastic manipulations. However, as will be shown later, cleaned aponeurosis maintains its nutrition through its lymph-supply, and unites better when freed from overlying fascia and areolar tissue.

When the inguinal canal is exposed the cord having been dislocated and held downwards and outwards, the thickened edge of the transversalis fascia at the abdominal ring comes into view. This edge may be freed and defined by dividing the infundibuliform fascia by blunt dissection. Above and below, the limits of the ring may be determined. The upper border of the ring is usually covered by the muscles, and the lower when retracted exposes the epigastric vessels which should be actually located in all operations for inguinal hernia. The inner margin of the ring is free and will readily allow a finger to be passed into the properitoneal space. The outer margin should be displayed with care, otherwise the spermatic vessels or vas will be damaged. Note the interval between these structures. Torek takes advantage of this space, and in restoring the ring after excision of the sac applies his stitches to unite the opposite margins of the ring between these structures.

Below the epigastric vessels lies a weak or undefended space, the inner wall of the canal, and here a bulge may be noticed even where no direct sac actually exists. This is a common site for recurrence.

All students of anatomy are familiar with the peritoneal fossæ of the hernial regions. A fact which may have surgical significance and which has, I believe, been hitherto overlooked is that the two little fossæ, the fovea femoralis and the fovea over the obturator canal, lie at the apex of a larger funnel-shaped fossa with the following four boundaries: in front Poupart's ligament, externally the external iliac vessels, internally the obliterated hypogastric (umbilical) artery, and behind the vas or round ligament. This fossa may be termed the quadrilateral fossa.

FREQUENCY OF HERNIAL SACS.

I believe that either an actual or potential oblique peritoneal sac of varying size exists in all subjects. This is shown in Fig. 2, where the cord has been dislocated and is held over to the outer side. On dividing the infundibuliform fascia a white semicircular outline can always be seen which is the edge of a potential sac. It is not unlike a rising moon in appearance. I have never failed to demonstrate this in post-mortem examinations, and in all my operation cases where an actual hernia was present on one side a potential sac was always found on the other side when it was looked for. When opened the sac always admits at least one finger. In several of the sacs I have found adherent omentum, although there was no history of hernia. This potential sac is an incompletely obliterated processus vaginalis. The usual description of the normal anatomical obliteration of the process that has been accepted up till now does not take into consideration the persistent patency of the proximal half inch or more.

If these observations are accepted it follows that all oblique inguinal hernias are of congenital origin. A study of oblique sacs removed produces further evidence in support of this view, since areas of closure in the processus vaginalis can be demonstrated at all levels. Specimens taken from operation cases may be shown with: (*a*) a completely patent processus, passages, but must carry out investigations of those structures which lie in its neighbourhood

The routine procedure so commonly adopted in the treatment of urinary infections—namely, the institution of free diuresis, the use of urinary and alimentary antiseptics, and the introduction of vaccine-therapy—are, to my mind, to be deprecated until a thorough search for the presence of some factor predisposing to the incidence, the recurrence or the persistence of such infection has been sought for Of course, these investigations will from time to time fail to elucidate such a cause, which may remain undiscovered until some exploration is made or some incidental condition, such as occurred in this case, accidentally defines its presence, the finding of such a lesion may save our patients years of useless treatment

Essential or Idiopathic Hæmaturia.

There are many other causes of hæmaturia which might be discussed, but they need not be referred to here, as the mode on investigation is common to them all The aid of the cystoscopist, the radiographer, the pathologist and the chemist may all be necessary to our service, thereby demonstrating the necessity of good team work, with this tract the results show how valuable this collaboration may be, and how far it is possible to be almost accurate in the diagnosis of a given case Still, even with all these means of diagnosis, there remains one group which must be mentioned, for which no cause for the bleeding is discoverable; to this the term "essential" or "idiopathic" hæmaturia is applied

This used to be a fairly common diagnosis, but owing to our better equipment it is fast disappearing, as some responsible cause can be defined in many cases which hitherto would have been so grouped; one of the causes mentioned above was found after removal of the kidney, chronic nephritis was shown to be present in others, although clinically the patients showed no evidence of that condition But still, occasionally, kidneys bleed and are removed which show no discoverable lesion even after the most careful microscopic investigation, and more surprising still, the source of the bleeding often is not found In some instances, minute nævi have been demonstrated of so small a size as to be missed by one trained observer and found by another, probably this is the explanation of others Practically, it is not possible to recognise such lesions before the removal of the kidney, nor will it be possible until some genius invents an instrument through which the interior of the pelvis can be observed

Improved Standard of Treatment

The introduction of all valuable methods of investigation must necessarily lead to an improvement in our methods of treatment It is indeed interesting to compare the ease and certainty with which a stone of the kidney can be demonstrated and removed by pyelotomy with the problematical finding of our forefathers, amongst whose equipment was found a knitting needle with which to prod the kidney tissue to demonstrate the existence of the calculus, to be followed by an incision through the so-called bloodless line, inevitably causing severe damage to the kidney, often serious hæmorrhage, and possibly a subsequent nephrectomy

It is now possible to demonstrate by pyelography the degree of damage of the renal tissue caused by the stone, so that the surgeon, prior to the operation, may know whether or not a nephrectomy will be required In the case of a very small stone, where he may mistrust his ability to find it, he can actually demonstrate by the same investigation the site of the calyx containing it The introduction of the tests for renal function in cases of enlargement of the prostate, thereby demonstrating the damage done to the renal tissues by obstruction, has led us to select only such cases for an immediate prostatectomy in which the function of the kidneys can reasonably be expected to withstand the serious effects of the operation and to deal with the remainder by a two-stage operation. It has also taught us to be cautious in recognising the presence of two kidneys and to avoid the removal of the only or the only functioning kidney The demonstration of an early hydronephrosis has enabled us to carry out such procedures as will prevent the more complete destruction of the renal tissue which would otherwise have been inevitable, and the formation of those enormous cysts which might be mistaken for a similar lesion associated with the ovary Pyelographic examinations have also enabled us to recognise the existence of a malignant growth of the kidney at a stage with a reasonable chance of complete eradication, which would otherwise not have been demonstrated except by an exploratory operation or by the finding of a large tumour beyond the hope of removal

These are some of the advantages in which the modern methods of diagnosis of genito-urinary conditions have led to more efficacious means of treatment; but perhaps of still greater interest, certainly to the public, has been the introduction of methods of treatment by intravesical procedure, thereby avoiding cutting operations which are hated by man and lead to the loss of much valuable time, which is bound to be of an important consideration to the worker It needs only to mention the removal of vesical stones by lithotrity, the destruction of villous tumours of the bladder by fulguration, the encouragement of the expulsion of ureteric calculi by the passage of bougies or the introduction of oil and drugs through a ureteric catheter, the destruction of portions of the prostate by diathermy in cases not suitable for the major operation or where there is some special indication pointing out its advantage

Surely, the advances which have been made and those within such a short period of time would have been after the heart of the great master whose name this lecture commemorates

Hunterian Lecture

ON

RECENT ADVANCES IN

THE SURGERY OF HERNIA

Delivered before the Royal College of Surgeons of England on Feb 16th, 1927,

By ERNEST M COWELL, D S O, M D Lond,
F R C S Eng,

HUNTERIAN PROFESSOR OF THE COLLEGE, SURGEON TO
CROYDON GENERAL HOSPITAL

The surgical history of hernia dates back to time immemorial, the subject being referred to in the earliest writings of our craft There have been three main periods, according to the method of operative treatment employed

1 *The Age of Herniotomy,* when the sac was excised and ligatured Celsus and Galen, in the first and second centuries A D, described and practised this procedure At this time hernia was thought to be due to a "rupture" of the peritoneum Paulus Aegineta, of Alexandria, in the seventh century A D, taught that the condition was not due to a sudden giving way of the peritoneum, but rather to a gradual distension and protuberance Itinerant herniotomists flourished in the middle ages, men who operated on patients in large numbers and then moved on to the next town

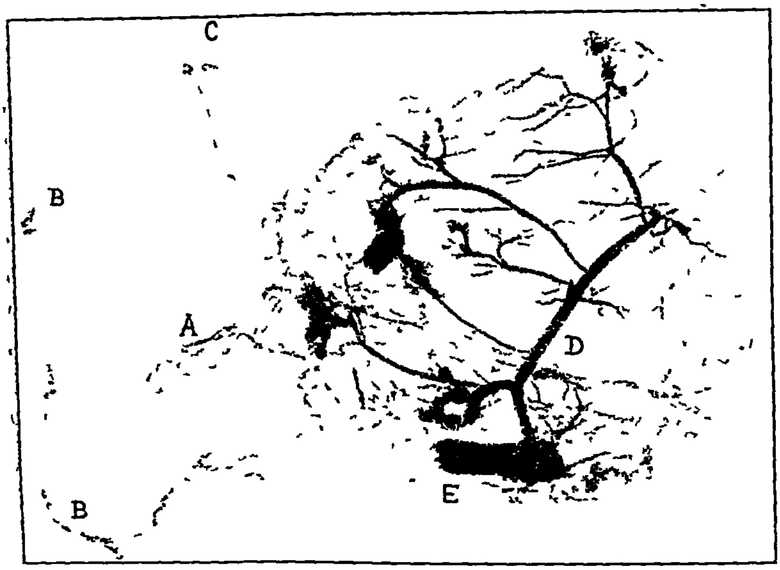
Pierre Franco and Ambroise Paré in the sixteenth century contributed to our knowledge of the condition In the seventeenth and eighteenth centuries, when the study of anatomy was being carried out by many skilful observers, several new types of hernia were described, and an extensive literature was compiled by such men as Littre, Petit, de Gimbernat, Richter, &c Early in the nineteenth century Scarpa in Italy proceeding a glistening fibrous band may appear running parallel to the epigastric vessels This is the obliterated hypogastric artery

Step 7—After careful inspection, to ensure that there are no adhesions or contents, the peritoneum is clamped by a succession of pressure forceps and is cut across The cut edges are united by thread and allowed to drop back

Step 8—The edges of the ring are closed and the thread with needle attached is left, in order to complete the suture of the flap later (A stitch)

Step 9—A flap of sufficient size to cover the undefended space without undue tension is cut from the cleaned inner part of the external oblique aponeurosis Below it is left with the internal pillar of the subcutaneous ring as its pedicle, and above it is made long enough to reach up to the abdominal ring It is usually about half an inch wide The outer ' slip" is next cut as long as possible ¼ to ½ in. in width, according to the thickness of the aponeurosis This is also left attached distally The "slip" is too short to work with comfortably and so is lengthened by being attached to a "loop thread" which carries the blunt-ended fascial needle

FIG 1



Injected hernial region, showing blood supply of external oblique A, cord B, reflected external aponeurosis C, fascia reflected from B D, epigastric artery E, iliac artery

Step 10—The flap is passed under the cord or round ligament and is stitched along its lower border to Poupart's ligament by means of the "slip" attached to the loop thread In order to make it fit snugly round the cord at its exit from the abdominal ring it is convenient in some cases to split the flap for half an inch or so The upper edge of the flap is now stitched to the transversalis fascia by means of the thread left for this purpose, and next to the aponeurotic surface of the conjoined tendon, or failing this, to the most convenient fascial structures

The remaining steps consist in suturing the oblique aponeurosis and closing the wound The operation usually takes about 25 minutes and both sides can be done by this method in an hour

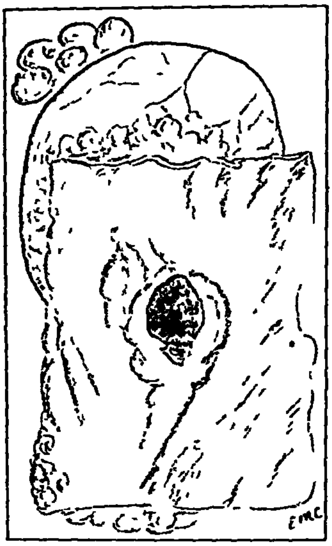
DIRECT INGUINAL HERNIA

Anatomy—A direct inguinal hernia is not so uncommon as was originally supposed It may occur in patients of all ages and is often bilateral As soon as the canal is opened and the cord or round ligament is lifted the spherical swelling of this sac comes into view, usually covered by vertical attenuated fibres derived from the conjoined tendon On division and retraction of the superimposed transversalis fascia the epigastric vessels are seen to course inwards above the sac Exposure of the root of the cord at the abdominal ring, by my method, will invariably display a small oblique sac This was pointed out by Hoguet and confirmed by Watson Below, the sac comes into relation with the bladder, and as the dissection of the slack peritoneum of this region proceeds the obliterated hypogastric artery is usually seen.

Morbid Anatomy—In a post-mortem specimen of an oblique-direct hernia (now in the Museum of the Royal College of Surgeons) it was possible in the fresh state to pull up the direct sac from beneath the vessels and convert the double hernia into one large oblique sac This is "Hoguet's manœuvre," and is an extremely important advance in the operative technique for this condition In Fig 4 I have shown this manipulation diagrammatically

The Operation—From these remarks it will be seen that the operative treatment of direct hernia need no longer present difficulties nor furnish such a high recurrence rate as at present—viz , up to 25 per cent The oblique hernia is found, the direct sac converted into one large oblique sac, and the operation completed by the author's usual flap hernioplasty In the 15 direct cases of the present series the results have all been satisfactory up to the present

FIG. 3.



Sac of femoral hernia

FEMORAL HERNIA

Anatomy—In considering the anatomy of the femoral hernia its close connexion with the inguinal region should be borne in mind In a dissection from the inguinal route the mouth of the sac commences behind Poupart's ligament The slack funnel-shaped peritoneal pouch above this is in intimate relation to the bladder and lies behind the fascia transversalis Externally in its fascial sheath lies the external iliac vein and behind the pubic ramus In the thigh the relations of a femoral sac are well known

Morbid Anatomy—A femoral sac is usually preceded by a portion of the properitoneal fat which is abundant in this situation This fat may be of considerable size and is probably a factor of ætiological importance Fig 3 shows a specimen illustrating the large amount of peritoneum that it is necessary to remove in the performance of an adequate operation, it may be contrasted with specimens obtained in the usual operations, when the sac is excised below Poupart's ligament There is some thickening of peritoneum round the mouth of the sac, but no " corns " or nodes are found as in the case of oblique inguinal sacs It is not uncommon for omentum to be adherent in the sac

Operation—The operation for femoral hernia should always be performed by the inguinal route The

the "congenital hydrocele"; (b) a tail-like processus, partial closure, (c) a fine fibrous cord attached to the usual potential sac.

Another condition which is evidence of the congenital origin of the sac and which occurred in 6 per cent of my cases is an encysted hydrocele of the cord Here the processus has undergone irregular obliteration, leaving an intermediate patent portion It is not uncommon to find this unobliterated portion without fluid contents, a potential encysted hydrocele of the cord In some cases there is hyperplasia of the processus vaginalis, with subsequent partial disappearance of a proximal portion of the peritoneal pouch and persistence of the vaginal portion with or without fluid contents This hernia with a potential vaginal hydrocele was described by Hey in 1764 as the "infantile type" When the hernial sac is accompanied by an actual hydrocele the condition is known as the encysted type of infantile hernia (Cooper)

The female analogue of Hey's or Cooper's type may occur Although a potential sac is so common it does not follow that hernia must develop As long as the "shutter" action of the muscles of the groin is maintained no oblique hernia will occur. This is an important fact in discussing the prevention of the condition

MORBID ANATOMY OF OBLIQUE INGUINAL HERNIA SACS

Examination of an adequately removed sac will demonstrate the large amount of slack peritoneum that may be removed The mouth of the sac from a boy 6 years old measured 7 cm, while in a young man of 23 years it was 9 cm in its longest diameter If the inner surface of the mouth of the sac be inspected, very often thickened rough areas may be seen, the corns of Villandré These rough areas may be seen in infants, and in elderly subjects may be calcified They correspond to the pressure area of the epigastric vessels

FASCIAL SURGERY

The work of Kirschner and others has already been mentioned In 1921 Gallie and Lemesurier began to publish the results of their experiments on fascial suture These observers found in studying cases operated on for recurrent inguinal hernia, where an operation of the Bassini type had been done, that in most cases no evidence of any previous muscle suture remained The same fact was also noted by Cudard and Jean in the following year A large series of experiments was carried out and the following conclusions arrived at (1) Edge-to-edge suture of fascial wounds is not strong, and is best when thread sutures are used (2) Overlapping does not add to the solidity of the scar (3) Cleaned fascial surfaces unite better than when areolar tissue is left between (4) Side-to-side suture of the undamaged conjoined tendon to Poupart's ligament never leads to permanent union (5) Pedunculated or free transplants of fascia and aponeurosis, if allowed an adequate supply of lymph, continue to live unchanged (6) Living fascial strips become rounded and are soon organised into fine tendons

In 1923 Seelig and Chouke published an important paper on a Fundamental Factor in the Recurrence of Inguinal Hernia They confirmed Gallie and Lemesurier's observations, and, basing their opinions on a large series of experiments, concluded that (1) normal muscle will not unite firmly with fascia or ligament, (2) fascia unites well with fascia, (3) a weak abdominal wall should be strengthened by a fascial method In 1924 Tinker and Sutton published similar results, and Adair, Eastman, and McEachern wrote on the surgery of fascial sutures Numerous surgical writers noted these experimental findings and the slogan "White to White" was taught In 1926, however, Koontz, repeating Seelig and Chouke's experiments, came to different conclusions He found that when "cleaned" or scarified muscle was sutured to "cleaned" fascia firm union resulted It was necessary, however, to prepare the surfaces very thoroughly and even to cut away a layer of muscle before suturing

From the practical point of view in hernia operations it is probable that in the majority of cases the conjoined tendon does not unite to Poupart's ligament To clean the surfaces as thoroughly as Koontz suggests is not practicable.

AN OPERATION FOR OBLIQUE INGUINAL HERNIA

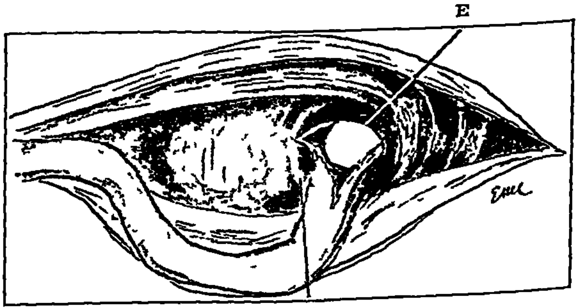
I have devised a form of hernioplasty which I have performed since January, 1925, in 125 cases, in 76 of which the operation was done on both sides—making a total of 201 flap operations

The operation may be described in the following 12 steps. 1 Hemi-semilunar incision 2 Division of external aponeurosis so as to allow of subsequent flap formation 3 Dislocation of cord or round ligament from canal, traction downwards 4 Definition of abdominal ring, commenced by division of inner part of infundibuliform fascia 5 Isolation of sac and separation of its base 6 Opening sac and pulling up slack peritoneum from below epigastric vessels 7 Excision and suture of mouth of sac 8 Closure of abdominal ring 9 Preparation of a pedicled flap from the inner portion of oblique aponeurosis and a smaller one ("slip") from the outer part 10 Suture of the lower border of the "flap" behind cord or round ligament by means of the "slip" to Poupart's ligament Above by a thread to aponeurotic or fascial tissue 11 Closure of external oblique aponeurosis by thread or free fascial sutures 12 Ligature of the vessels, suture of superficial fascia and skin

Step 1—In making the incision on the left side of the patient the operator's index-finger rests on the anterior superior iliac spine, his little finger on the pubic spine, and the remaining fingers are allowed to take up their natural position With the skin held tense the knife is swept round through a quarter of a circle from the little to the middle finger Vessels are picked up before division if possible and the incision deepened until the shining oblique fibres are seen In the case of a right-sided incision the position of the fingers is reversed The little finger rests on the iliac and the index on the pubic spine The incision is then made from the ring to the index-finger through a quarter of a circle

Step 2—As a rule the larger flap will be taken from the inner part of the oblique aponeurosis The incision to open the canal will therefore be made nearer to Poupart's ligament than in the ordinary operation Sufficient aponeurosis must be left on the outer side to form the pedicled strip used subsequently as a suture ("slip)" These flaps are not cut until later

FIG 2



Abdominal ring showing edge of transversus fascia A, "rising moon" potential oblique inguinal hernia appears E, epigastric artery beneath fascia

Steps 3 and 4—Holding the cord outwards, after dislocating it from its bed, gives the operator full access to the sac with the minimal disturbance to the cord and its coverings Division of the upper part of the infundibuliform fascia on its inner side enables a small sac to be found with great ease as already described

Step 5—A very important point is the thorough isolation of the base of the sac, by sweeping the finger round in the interval between peritoneum and transversalis fascia The epigastric vessels will be seen during this manœuvre The rest of the sac is usually easily isolated by gauze dissection

Step 6—The sac is opened on its inner side and a finger introduced The slack peritoneum is then drawn up from under the epigastric vessels until first the supravesical fat and then the bladder itself come into view During thi

Hopkins Hospital gave a recurrence rate of 5 6 per cent out of 816 oblique and 29 7 per cent. in 94 direct hernias

The time interval between date of operation and recurrence is interesting 98 6 per cent of recurrences showed themselves by the end of the second year Of these 90 per cent had occurred at the end of 18 months, 73 9 per cent at the end of 12 months, and 47 9 per cent within six months

The results of a series of 3000 hernia operations were reported in 1924 by B L Coley, of New York The author has published a full analysis of these statistics elsewhere In children the recurrence rate is nil In adults Coley gives 8 7 per cent and 4 4 per cent recurrences in males and females respectively in the case of oblique inguinal hernia, while in the direct variety it is 16 4 and 50 per cent In femoral hernia in 80 cases the recurrence rate was 9 per cent in males and 14 per cent in females In 47 cases of recurrent inguinal hernia a Bassini or modified Bassini type of operation had been performed in each case

With regard to fascial surgery and hernioplasty, sufficient time has not yet elapsed nor have surgeons performed a large enough series of operations upon which to base a final judgment Gallie and Lemesurier quoted a series of 60 cases in 1923 without recurrence, McArthur in the same year 100 without recurrence In 1925 Goldenberg stated that Wainschenker, of Czitomir, had performed since 1923 125 hernioplasties with pedicled autoplastic sutures, with only one recurrence In the past two years the author has performed his flap hernioplasty on 125 individuals, in whom the opposite side was also dealt with in 76 cases, making a total of 201 flap operations So far a single recurrence has been observed It seems probable therefore that in hernioplasty an operative technique has been found which will give perfect and absolutely reliable results

In conclusion I wish to express my thanks to Prof Sir Arthur Keith for the inspiration and valuable help he has readily given at all times The specimens taken from the operation cases have been prepared and mounted by Dr. C. F. Beadles, to whom also I express thanks

---

CONTROL OF SCARLET FEVER IN A CHILDREN'S HOSPITAL.

By D McCLEAN, M B, B S Lond,
ASSISTANT PATHOLOGIST, HOSPITAL FOR SICK CHILDREN,
GREAT ORMOND-STREET.

A case of scarlet fever in a children's ward is always a cause of anxiety to hospital authorities, and has hitherto involved the cancelling of all admissions to and discharges from the infected ward for a period of not less than ten days Scarlet fever occurs more frequently in surgical wards and, when the infection spreads, may gravely impair the results of operative treatment Furthermore, the necessary closing of the ward entails lengthening of the usually overcharged waiting-list.

On referring to the records of the incidence of scarlet fever at this hospital during the last few years one finds considerable variation in the spread of the, infection in the exposed wards from year to year For example, in 1923, 26 cases of scarlet fever occurred in the wards of the hospital, of which only six contracted the disease from patients already in the wards The remaining 20 were all isolated cases occurring in different wards at different times In 1924, however, there were 31 cases, 15 of these were infected by contact in the wards with eight cases These involved quarantine of the wards concerned for periods varying from 10 to 22 days

The introduction of the Dick test and the possibility of protecting susceptible (Dick-positive) patients by the injection of specific antitoxic serum suggested a procedure in exposed wards which it was hoped might prevent the spread of infection, make it possible to eliminate the quarantine period, and carry on with the operative treatment of the patients in the ward.

Preventive Procedure.

Since January, 1925, the procedure detailed below has been adopted immediately a case of scarlet fever has been notified in a ward, and while the results of this procedure have been under observation, the quarantine period of 10 days has been maintained in order that the contacts might be watched for any further developments (1) All the patients in the ward were Dick-tested as soon as practicable. (2) The following day all Dick-positive children were given 5 c cm of scarlatinal antitoxic serum intramuscularly (3) On the third day these positive children were re-Dick-tested, and if any were found to give a positive or doubtful reaction a further dose of serum was given

The technique adopted in Dick testing was that suggested by Dr. R A O'Brien of the Wellcome Physiological Research Laboratories—namely, the intradermic injection of 0 2 c cm. of a 1/1000 dilution of the toxin obtained from the scarlatinal streptococcus. At the same time a control injection of 0 2 c cm of 1/1000 heated toxin (2 hours at 100° C) was given The tests were read at 10 hours, 18 hours, and 24 hours approximately A positive reaction showed a deep red blush with a circumscribed area of from 20 to 30 mm in diameter at the test injection with no reaction at the control injection. A few doubtful reactions showed a definite blush with a smaller diameter than this, these were regarded as positive for the purpose of this investigation and were protected with serum. There was no difficulty in reading the results of these tests, the reactions being marked in most cases. Very few pseudo-positive (cases in which the control injection produced a reaction) results were obtained. Infants may be difficult to test because of the extreme thinness of the skin, laxity of the subcutaneous tissues, and their disinclination to keep still The appearance of a definite intradermic bleb on injection indicates that this has been successful Subsequent observation was made for: (1) The occurrence of scarlet fever in these contacts (2) The incidence of serum rashes and the occurrence of any other unfavourable symptoms which might be attributed to the serum.

Results.

So far, 25 wards containing from 20–30 patients in each have been treated in this manner *In only one of these wards has a second case of scarlet occurred amongst the patients exposed to infection.* This one exception was significant; it occurred during the early period of this procedure, when the known methods of standardising the serum were very much more unsatisfactory than they are now. On retesting the cases which had received the serum, it was found that many of them had not been converted into Dick-negatives and a further injection of serum was necessary It was during the delay entailed in obtaining a fresh batch of serum that two further cases of scarlet fever occurred in the Dick-positive patients On two separate occasions a nurse in the infected ward contracted scarlet fever in the quarantine period After the first two or three outbreaks testing of the nurses was not done It was not considered advisable to give them a temporary passive immunity in view of their liability to further exposure to infection; an active immunisation routine for the nursing staff had not been developed and, owing to shortage of staff, it was not possible to isolate the Dick-positive nurses for the necessary quarantine On neither of these two occasions were any of the protected children infected by the nurse.

The proportion of Dick-positive children (aged infancy to 12 years) varied from 30–70 per cent in the batches tested The proportion developing serum reactions varied enormously in different wards and with different batches of serum. In the majority of wards only one or two children would show a transient urticarial rash. In a few wards, however, there were many such rashes with some pyrexia and, occasionally, author employs his usual hemi-semilunar incision, splits the external oblique, raises cord or round ligament, incises the transversalis fascia, and isolates the neck of the sac by gauze dissection In the case of a strangulated hernia or if the accompanying peritoneal fat is too large to pass up through the femoral opening in Poupart's ligament, the fibres of the latter are incised inwards towards the pubic spine After a wide excision and suture of the peritoneum, during which the bladder is always seen, the incision in the transversalis fascia is carefully sutured The opening in Poupart's ligament is closed by a pedicled flap, taken usually from the lower portion of external oblique, and is secured on the upper surface of the ligament by a pedicled autofascial suture, a free fascial slip, or by thread Occasionally a free fascial graft may be advisable In one case where a large strangulated hernia existed it was found necessary to divide the fibres of Poupart's ligament transversely The resulting gap was closed by a pedicled flap and clinically it is impossible after 18 months to detect any weak spot The difficulty in suturing a divided Poupart's ligament is well known, and although numerous methods have been devised for its restoration, none of them have ever been satisfactory

Hernioplasty in Ventral Hernia

I do not propose in this lecture to enter into any detailed description of ventral hernia and its operative treatment Fascial surgery affords eminently satisfactory results Gallie and Lemesurier have described an elaborate technique, utilising 8-inch lengths of living fascia lata taken from the patient's thigh I have modified and simplified the technique enabling the surgeon to deal with 3- or 4-inch lengths (Fig 5) The short lengths of fascia, one-sixth of an inch wide, are prepared by an assistant and kept in warm saline until required In order to make the strip long enough to work with, a " loop thread " is attached by turning one end of the fascial slip over the thread and tying off by a stitch, which also pierces the fascial strip The other end carries a tail or fixation stitch, threaded on to an ordinary round-bodied needle The fascia needle attached to the " loop thread " is specially devised to push its way through aponeurotic tissues without cutting the fibres If more than one suture is required the loop end is fastened off by the fixation stitch of the next suture, and so on This combination of thread fascia is easy to work with Fascia is a slipping tissue and is not easy to manipulate as described by Gallie and Lemesurier

In repairing a large ventral hernia it may be possible after a wide dissection to prepare sound edges suitable for fascial suture If the component layers of the abdominal parietes are attenuated or even missing, the weakened wall may be reinforced by free fascial grafts taken from the patient's own thigh and secured by fascial stitches

In a case operated on nine months ago the patient, a woman of 50, presented a very thin abdominal wall, weakened by four previous laparotomies and severe X ray burns sustained during treatment following a hysterectomy for malignant disease On admission to hospital a loop of small bowel was found protruding through the skin over the centre of one of the scars A transverse incision from one superior iliac spine to the other was made and no trace of the lower portion of either rectus could be found The slack peritoneum was plicated and covered by large fascial grafts. Over this was stitched the skin, which was only half its usual thickness The patient has now a very thin abdominal wall, but has no actual hernia and is able to get about and do her household work

A filigree would probably not have been of use in this case

Filigree Methods.

The silver filigree described by Bartlett and introduced into this country by Laurie McGavin in 1911 was at one time extensively used in the treatment of large ventral hernias The filigree tends to break up in the tissues after a time and the method has been gradually discarded With smaller filigrees the wire is not subjected to the same strain and the network may still be seen intact and in position, even after three or four years

Recurrence.

Causes —An excellent paper was published on this subject in 1922 by two French naval surgeons, Oudard and Jean Their conclusions were based on a study of 145 observations made at the time of the operation for recurrence The chief points noted were (1) The skin over the hernia sac is generally found adherent to the underlying aponeurosis, and signs of former suppuration are present (2) There is a gap in the external aponeurosis (3) In the case of a Bassini operation the muscle-fibres are found to be atrophied, especially after suppuration (4) The sac in the case of direct hernia simply reappears In oblique hernia a loculus or saccular diverticulum is usually found. This was overlooked at the original operation

In the list of operation faults these authors give the following as favouring recurrence: (1) Insufficient resection of sac (2) Mal-ligature of the sac (3) Inclusion of sac contents (4) Persistence of a too patent abdominal ring (5) Bad closure of parietes. (6) Omental adhesions to line of suture of sac mouth. (7) Suppuration

Fig. 5.

B suture passed, taking in varying amounts of aponeurotic fibres C, fastening off head of stitch

A study of this list of faults will show that they are all provided against in the author's hernioplasty

Frequency of Recurrence —The most recent English figures collected are those of Surg -Commander H E R. Stephens, published in January, 1927 In some 2000 cases including inguinal, femoral, and umbilical hernias, the recurrence rate was found to be 10 per cent. Of these cases which recurred 10 per cent were operated on prior to admission to the Royal Navy, by a number of operators, many of whom undoubtedly possessed little opportunity for the frequent practice of herniorrhaphy In America Erdman published in 1923 records of the late results of 978 traced cases of hernia operations The total recurrence rate was found to be 6 67 per cent, 3 15 per cent in oblique and 16 61 per cent in direct hernias Another series published in 1920 by A S Taylor from the Johns the possibility of improvement Latterly, seven or eight rigors have been considered quite sufficient in the majority of cases, and in many of them even fewer have been found efficient in procuring an amelioration The average number of rigors in this hospital has been seven

No difficulty has been experienced in the termination of the malaria by quinine sulphate A few spontaneous cessations of malaria have occurred, but quite a reliable history of tropical malaria has been obtained in such instances—a point to be considered, especially in comparison with the disappearance of the pyrexia of renewed therapeutic infections (see below)

Relapses have occurred after all methods of infection, but most infrequently when the intramuscular route has been used—that is, in two instances only

Post-malarial Period

No spectacular results are to be looked for either during the malarial period or immediately after Although it is true that in certain cases a mental improvement seems definitely to commence at the height of the pyrexia, yet on the other hand a number of patients become acutely maniacal at this time The improvement, if any, tends to be much slower from the mental standpoint than from the physical, and may be long delayed Considerable disappointment is sometimes experienced in patients who show some amelioration shortly after the termination of the malarial attack, but who later relapse The physical condition is one of anæmia, which readily responds to iron and arsenic, and the weight of the patient should steadily increase with the passage of time Unfortunately, however, the mental improvement is by no means always in line with the bodily progress, as is evidenced by the number of patients still remaining in this hospital, of whom only four are confined to bed

One result of the treatment stands out pre-eminent: the habits of the general paralytic are but rarely good, yet after malarial therapy an improvement is noted in the great majority of cases, the faulty habits becoming clean, to the great convenience and comfort of patient and staff

Serological Changes

Careful records have been made here of the serological investigations carried out before and after treatment, and definite changes in the reactions of the cerebro-spinal fluid have been found at varying periods after malaria No generalisation can be indulged in, but in numerous instances the excess globulin is found to disappear about 12 months after the termination of pyrexia, and the gold-sol reducing power of the fluid is diminished at or soon after that time The acetic-anhydride reaction has, too, sometimes been found definitely negative after malarial treatment, although it seems much less prone to alter than the other serological tests A diminution in the cell-count is frequently evident and is sometimes very marked In a large number of cases such changes do not occur pari passu with clinical improvement, one of the worst cases at present in hospital has a colloidal gold reading of 0001110000, with negative globulin, whilst a patient who has improved almost to the point of discharge shows a gold curve of 5555554330, with a weakly positive globulin

Again, we have seen cerebro-spinal fluids which, after a period of partial "clearing," commence to recede—e g, a patient whose fluid was improved to the point of giving a reading of 2345543000 with negative globulin and acetic-anhydride reactions, subsequently gave, two years after malaria, 5555553220, with positive globulin and acetic-anhydride results and an increased cell-count. In spite of this the patient is making marked mental progress

General Treatment

The various arsenical preparations have been extensively used in after treatment, but apart from their general tonic effect they have had no influence on our patients' condition, and do not seem to have assisted in "clearing" the cerebro-spinal fluid, indeed, it has been our experience that where "914" has been administered the Lange's reading has seldom altered This cannot be taken as a fact of value, because so many cases showing mental improvement continue to give true paretic curves Use has also been made of such preparations for the termination of pyrexia, but the success has only been partial in that parasites have still been found in the peripheral blood long after the abatement of temperature

For over two years mercury and potassium iodide have been given for long periods as a routine, and these combined drugs appear to have lessened the incidence of seizures of a cerebral type in all but the failing patient. The iodide is, of course, given in increasing doses, and only in two cases has any suspicion of iodism been noticed Cerebral seizures before treatment have been comparatively common and several patients have had them during the earlier period of malaria: it is now the exception to have such occurrences in general paralytics under treatment, and where they are observed it is a good ground for a poor prognosis

It is the rule here to endeavour to keep treated cases of general paralysis under observation for at least nine months or a year The wisdom of this course has been demonstrated frequently, for there is sometimes a spurious improvement in the mental condition which gives place within three or four months to a lethargic type of grandiose behaviour, very frequently accompanied by an enormous appetite We might instance one such patient who can readily eat three full dinners at one meal, and then say he is hungry. Quite a number of the discharged cases evinced little mental betterment for the first year after malaria, and it was only at the end of that period that a slow return to mental health commenced

Second Attacks of Induced Malaria

Where no assessable improvement has ensued, and where the physical condition permits, an attempt to induce a second series of rigors is made This, however, has proved a matter of great difficulty in a considerable number of cases, for there seems to be a very well-defined resistance of the body to the parasite, and no satisfactory explanation can be advanced to account for this state of things

Resistance has been offered to both the natural and "unnatural" infections, patients have been resistant to intramuscular and intravenous infections and have yet had this resistance overcome by mosquitoes, a few have been resistant to mosquito bites (of mosquitoes which were known to be infective and which had infected other patients within 20 minutes), and these have developed malaria by a patient-to-patient infection, again, a very few have proved to be resistant both to mosquitoes and to injection of known malarial blood Such immunity does not appear to be explicable by reference to the original source of the primary attack, its length, the incidence of relapses, the age and conditions of the patient, or their blood groups In fact, no constant factor is ascertainable in this class of patient, possibly it lies within the sphere of biochemistry The second incubation period bears a close resemblance to that of the primary attack, taking into account the route of infection employed The incubation period for any individual case, however, may vary by quite a few days in the second attack as compared with the first

When malaria is induced by therapeutic methods for a second time, another factor has to be reckoned with The primary attack seldom "cures itself" and quinine has to be exhibited in the ordinary way In the second attack, however, it is almost the rule to find a spontaneous remission, pyrexia disappearing before the parasites Soon after, however, the blood film becomes and remains negative Nowadays, when a patient shows a spontaneous remission in what is regarded as the primary attack, it is enough to make one almost certain that he has previously had malaria diarrhœa The type of reaction varied Usually there was some pyrexia, 100° F —and in a few cases 102°—during the 24 hours following injection This might, or might not, be associated with the later rash In all cases the reaction appeared to be very much milder than that of adults The children did not complain of joint pains and did not appear to be ill I had thought this variation to be largely attributable to the batch of serum employed, but Dr O'Brien informed me that the sera were all "pooled" batches from various horses and he suggested that these variations might be due to the relatively small number of patients (20 to 30) in each series

So far no superiority of the concentrated over the unconcentrated serum has been observed in Dick-conversion or the production of serum reactions However, a routine injection of 5 c cm of serum was always given, and no attempt was made to compare the minimal doses of the two types of serum which would convert Dick-positives into negatives in parallel cases On a few occasions, owing to a later outbreak of scarlet fever in a previously infected ward, it happened that a child previously Dick-positive was retested and had to be protected again In these cases, prior to inoculation with the serum, an intradermal injection of 0 2 c cm. of 1/100 dilution of the serum was given, and the child watched for half an hour for the development of local or general reaction. No cases of anaphylaxis occurred

No systematic observations of the duration of the passive immunity afforded by the serum were made On re-Dick-testing children in the subsequent outbreaks referred to above, after intervals of a month and six weeks, it was noticed that in about half a dozen cases the Dick test was undoubtedly modified by the previous dose of serum In none of these cases was the reaction absolutely negative, but it was fainter and more diffuse, in two of these cases there was a pseudo-reaction with the control

In view of our experience with these 25 outbreaks, it has been decided to adopt this procedure as a routine in future, to ignore the quarantine of the ward, and to proceed with operations, admissions, and discharges In fact, this has already been done in two wards without any untoward result

Another use of the Dick test may be noted in this connexion In December, 1924, three cases of suspicious sore-throat with pyrexia and vomiting had occurred in one ward These had been regarded as possible mild cases of scarlet fever, and they had been isolated together with three contacts No rash or peeling had developed It was desired to clear up the diagnosis in order to return these patients to a general ward Dick tests were carried out three weeks after the incidence of the sore-throats The three affected children all gave positive reactions Two contacts gave negative results and one was doubtful Therefore it was presumed that these sore-throats had not been scarlatinal and the patients were returned to the general ward. No further cases of scarlet fever occurred in the ward

Summary.

(1) The procedure adopted in 25 wards containing from 20 to 30 patients suggests that the spread of the infection can be controlled No second case of scarlet fever occurred in any of the protected patients (2) No effects dangerous to the patient could be traced to the Dick test or serum injection, though, in a small minority of cases, the serum reaction was severe enough to cause pyrexia and some diarrhœa extending over a few days (3) This procedure would appear to be applicable to schools and institutions other than children's hospitals

I am indebted to the honorary staff of the hospital for permission to publish these results obtained from observation of cases under their charge to the resident staff for their co-operation in reading the tests and injecting the serum, to Dr R A. O'Brien of the Wellcome Laboratories of Physiological Research for supplying toxin and serum, and to Dr D Nabarro in whose department the work was done.

MALARIAL THERAPY IN GENERAL PARALYSIS OF THE INSANE.

A REVIEW OF THREE YEARS' WORK

By JOHN P. STEEL, M D Edin,
ASSISTANT MEDICAL OFFICER, COUNTY MENTAL HOSPITAL, WINWICK, WARRINGTON,
AND
J ERNEST NICOLE, L M.S S A Lond,
SENIOR ASSISTANT MEDICAL OFFICER TO THE HOSPITAL.

The treatment of suitable general paralytics by malaria was commenced at this hospital a little over three years ago, and has since been carried on systematically During this period more than 150 cases have been diagnosed clinically and confirmed in the laboratory, a large number of which have been subjected to malaria, and the general results and observations made thereon are quoted below Very few definite conclusions can be arrived at in so short a space of time, and only tentative opinions as to the value of the treatment can be offered

Of the total number admitted only 28 cases have not been treated and all these have since died, of the remainder, 13 failed to develop malaria, and these have also died, 120 patients have had induced malaria, but 10 of these are too recent to be included in our discussion of results, 38 deaths have occurred amongst those who have had malaria, 2 have been transferred, and 26 discharged, leaving 54 presently in hospital

Admitted	161	Died treated—	
		Malaria	38
Inoculated—		No malaria	13
Malaria	120		
No malaria	13	Died untreated	28
		Discharged	28
Not treated	28	Remaining	54

Primary Infection

Infection has been conveyed to the patients by all routes, and an analysis of the successful cases is as follows —

Mosquito Infection —24 cases, the longest incubation period was 22 days, the shortest 8, and the average 13 days

Intravenously —25 cases, the longest incubation period was 22 days, the shortest 4, and the average 12 days

Intramuscularly —70 cases, the longest incubation period was 25 days, the shortest 5, and the average 12 days

Subcuticularly —One case only, with an incubation period of 19 days

The length of the incubation period seems to have little or no relation to the season of the year

As a rule, where mosquito infection has been used, the parasite is found in the peripheral blood two or three days before the onset of pyrexia, where, however, the "unnatural" route is chosen, pyrexia precedes demonstrable parasites

A feature of interest in the incubation period is that, concomitant with the gradual lowering of the hæmoglobin content of the blood during the few days prior to the first real rigor, smaller rises of temperature may be noticed, seldom reaching higher than 100° F From the periodicity of these minor rises, it is often possible to foretell the type of the oncoming malaria These minor rises may well be due to the liberation of those toxins without the presence of which Stitt considers a true malarial rigor can not be produced In answer to the possible objection that many patients do not show these preliminary and mild rises of temperature, it may be pointed out that in numerous cases where these signs are absent the first true pyrexia is unaccompanied by the shivering of rigor

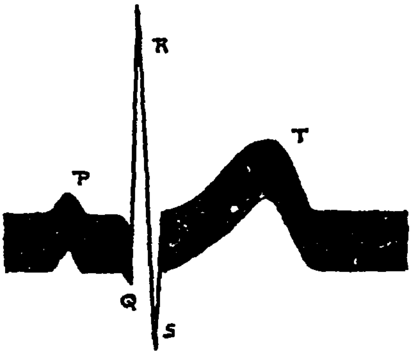
Period of Pyrexia

Although all malaria conveyed to patients has been of a known benign tertian type, there has been no certainty of periodicity in pyrexia; mosquito-borne malaria has, on the whole, proved more true to type in this respect Little need be said about the actual malarial period, in the earlier days it was considered that the greater the number of rigors obtainable, the greater and the extent to which it is damaged—e g., if the auricle is chiefly involved an auricular irregularity or tachycardia commonly results, while if the bundle system is chiefly affected some variety of heart-block results.

Fig 1 shows a normal electrocardiogram P, Q, R, S, and T being the waves produced by auricle, right and left ventricles, and the aortic base respectively, and P-R the time interval taken by the contraction wave to traverse the bundle of His.

Figs 2 and 3 are diagrams of typical electrocardiograms (lead 2) from cases of ordinary physiological tachycardia and well-marked Graves's disease.

FIG 1.



Normal electrocardiogram. The mean of a number of curves taken from healthy students (lead 2.)

Certain differences will be noted (1) While in physiological tachycardia (Fig 2) the P waves are always smaller than the T, it will be seen that in the case of acute thyrotoxicosis (Fig 3) the P waves reach the level of the T waves; either, therefore, the auricular contractions in Fig 3 are relatively greater than in the other case, or the contractions in the regions of the ventricular base are smaller. In either case this alteration, implying as it does auricular over-action or alternatively an impairment of function in the region of the base of the ventricle, points to some change in the heart musculature. (2) In Fig 2 the P-R interval is within the normal (0 2 seconds), in the case of Graves's disease this is often increased, indicating delayed conduction in the bundle of His.

It is well known that auricular fibrillation—a manifestation of gross damage to the auricles—is common in Graves's disease.

Probably enough has been said to indicate that electrocardiograms in Graves's disease show that there are good reasons for believing that degenerative changes take place in the myocardium.[1] In 1917, in a paper enumerating the causes of sudden death Sir Bernard Spilsbury[2] pointed out that "exophthalmic goitre occupies an important position as a disease liable to cause sudden death owing to secondary disease of the heart muscle. . . death may occur suddenly with no apparent cause."

It is this secondary disease of the heart muscle, still sceptically regarded by many, with which we are concerned here. We submit that it is well illustrated in the following case.

Clinical Record

N M, a previously healthy young woman, aged 21, consulted her doctor in February 1924, because of palpitation. There was not much enlargement of the thyroid at this time, nor any sign of exophthalmos, but her condition became worse, and early in August a diagnosis of well-established exophthalmic goitre was made. She rapidly became worse and later in the month was sent to hospital. She then presented all the cardinal signs and appearance of a typical, well-marked case of acute Graves's disease.

As six months' medical treatment had proved ineffective, it was decided to attempt to reduce the degree of thyrotoxicosis by cutting off part of the blood-supply to the thyroid. She was much too ill to be subjected to an anæsthetic and partial thyroidectomy and so, nine days after her admission, polar ligation of the right superior thyroid artery was performed under local analgesia. After this there was a distinct improvement in her condition. She stated that she had not felt so well for a very long time, but a fortnight later she had an attack of acute thyroidism which, it was thought, would prove fatal. The intensity of this attack subsided somewhat, however, and six weeks after the first ligation, with a view to checking still more the degree of intoxication, the *second* superior thyroid was tied under local analgesia.[3] Forty-eight hours afterwards, however, she had another exacerbation which proved fatal.

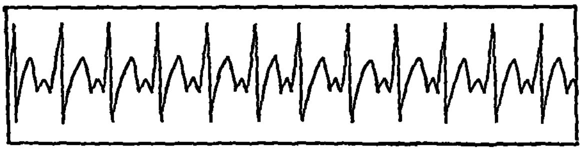
At no time while the patient was under observation in hospital did she suffer from auricular fibrillation; the pulse was regular, its rate varying from 96 to 160 beats per minute. The case was an advanced and very acute one that showed little or no response to rest or medical treatment. Subsequent examination has shown that the damage to the heart muscle was such that but little could have been expected from surgical treatment had it been possible suddenly to put out of action the over-active thyroid.

Pathological Findings.

After death the right side of the heart was found to be dilated, the valves were healthy in appearance and competent, and wherever it was cut the muscle *appeared* healthy and normal in thickness and colour. One could quite understand why many maintain that in these cases the heart action is a functional disturbance. However, the microscopic appearances in this case have shown beyond doubt that there was diffuse myocardial degeneration present.

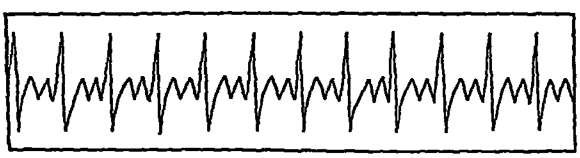
Sections were cut from both auricles, both ventricles, and the region of the interventricular septum. These were stained with hæmatoxylin and eosin, and then other methods, Gram, van Giesen, and Weigert's fibrin-staining were tried to heighten the contrast.[4] The outstanding feature of these sections is necrosis of bundles of muscle-fibres scattered amongst apparently healthy fibres. This is shown in the accompanying microphotograph (Fig 4). Evidence of the intensity of the toxæmia is gathered from the fact that in some of the sections certain of the necrosed muscle areas are free from invading cells, whereas as one would expect other areas are markedly infiltrated, probably with a view to absorption of the necrotic *débris*. An enormous preponderance of polymorphonuclear leucocytes is seen in the section of the left auricle, but the process of scattered muscle-fibre necrosis is apparent in both auricles and both ventricles. Some capillaries are found choked with cells which can be seen infiltrating surrounding necrotic areas.

FIG. 2.



Physiological tachycardia. T waves considerably greater than P waves.

FIG 3



Tachycardia in well-established thyrotoxicosis. T waves = P waves.

A close examination of all sections shows the most marked and most recent degeneration, probably the immediate cause of death, in the right ventricle, where large areas of necrosis, devoid of any infiltrating phagocytic cells are apparent, the least change in the region of the interventricular septum and the oldest changes, judging by the concentration of infiltrating cells, in the auricles.

These changes are what we should expect from the clinical findings. It will be remembered that post mortem there was right heart dilatation, that during

---

[2] Sudden Death, Practitioner, 1917, p 132.

[3] From recent investigation we are now of opinion that it would have been preferable to have tied the inferior artery of the same side as the previous ligation.

[4] For the sections we are indebted to Mr. C R Drury.

Quite what bearing such "immunity" and spontaneous remission have in the sphere of preventive medicine it is not our province to decide It may be that "unavoidable" malaria is cut short as quickly as possible with the prevention of antibody production, if such production occurs, in induced malaria, on the other hand, the fever is definitely encouraged and allowed to continue as long as the patient is equal to the strain Against this, however, must be placed the fact that, where the physical condition of the patient has demanded it, the infection is quickly terminated, despite but two or three rigors; in such cases the same immunity has been experienced, whilst mosquito-infected patients who have had a relapse of malaria are also known to have shown quite a definite resistance Whatever the reason, the second induced attack is usually of much shorter duration and, although the rigors are true to type, the frequency of spontaneous remission has been such as only to permit our patients to have on an average five high fever reactions

On the whole the second attack drains the system of most patients to a less degree than does the first The exception to this is the patient who, in the intervening period, has become excessively fat Nowadays such a patient is left severely alone, and no attempt is made, whilst he is in this condition, to infect him again The unhealthy fat seems to overtax the heart to a marked degree, and further malaria puts too great a strain thereon Second infection has been only attempted with such patients as have made no definite mental progress, an interval of approximately one year, and frequently longer, has been allowed to elapse before such attempt was made That a second induction is justified is proved by the fact that of the 30 cases reinfected 3 have been discharged, 4 are doing really well, whilst 5 have shown some improvement

Conclusions.

It is rather difficult to assess the value of the malaria treatment, and certainly no opinion can be given with authority such as is given by the German observers who claim to have had patients discharged and usefully employed for seven years No such opportunity has been enjoyed as yet, and our results are not so happy

Although we have discharged 26 patients, 3 of these are known to have been readmitted to other hospitals in a definitely relapsed condition, and 2 others have been returned to us, moreover, we have here at present 2 cases treated at other mental hospitals who had subsequently relapsed On the other hand, we have heard of some of our patients who have been at work for more than a year, and of one who has been discharged for more than two years and shows no signs of a relapse Excluding the 10 most recent cases, and allowing for such relapses as are known to have occurred, the recovery rate works out at 20 per cent Possibly, owing to earlier diagnosis elsewhere, the cases admitted recently have been of a type which will respond and are actually responding more satisfactorily to the malarial therapy

In view of the hitherto almost hopeless prognosis in general paralysis of the insane the percentage recovery (or remission) we have obtained seems to be complete justification for the use of malarial therapy In addition, from a hospital point of view the treatment is certainly well worth while, as the patients become much more easily dealt with, and, in fact, if the only improvement to be found was in their habits (which almost invariably become clean) the advantages accruing therefrom would be sufficient to warrant the work

We would wish to record our acknowledgments to Dr T W Davidson, late of this hospital, who published some details of the first results obtained, early in 1925 To the medical superintendent of this hospital, Dr F M Rodgers, we are again indebted for permission to use hospital facts and figures, and for much kindly supervision

THE NATURE OF
THYROTOXIC MYOCARDITIS

By J STRICKLAND GOODALL, F R S Edin, F R C S Edin, M B, M R C P, M S A Lond,
PHYSICIAN TO NATIONAL HOSPITAL FOR DISEASES OF THE HEART, LATE LECTURER ON PHYSIOLOGY AND SUB DEAN, MIDDLESEX HOSPITAL
AND
LAMBERT ROGERS, F R C S Edin, M R C S Eng,
MEMBER JUNIOR CANDIDATE GROUP, AMERICAN COLLEGE OF SURGEONS, ASSISTANT IN SURGICAL UNIT, WELSH NATIONAL SCHOOL OF MEDICINE, THE ROYAL INFIRMARY, CARDIFF

That sustained thyrotoxicosis ultimately results in definite myocardial degeneration is by no means accepted universally It is our intention here to endeavour to establish this thesis

Frequently one hears the disordered heart action in exophthalmic goitre referred to as functional, and although it is well known that cases of Graves's disease may die suddenly, the heart failure has been regarded by many merely as the outcome of exhaustion following the rapid heart action

On consulting a number of recent text-books of medicine we find that where reference is made to the morbid histology of Graves's disease, mention is made of the thyroid, the thymus, the cervical sympathetic ganglia, the blood, the brain and spinal cord, the spleen, cervical and bronchial glands, even Peyer's patches, but that references to the heart are conspicuously wanting In one work we read that in some cases the heart is dilated and that valve trouble may be present, while according to the author the sympathetic ganglia have been found to be diseased also Another writer states that in the great majority the heart is perfectly sound, and that after death in uncomplicated cases the heart is found to be normal in both the valves and the muscular tissue We cannot regard these findings as typical

One of us (J S G) has for a number of years maintained, and to the satisfaction of many demonstrated by means of the electrocardiograph, that definite myocardial damage does occur[1] In this paper it is our purpose to refer to the morbid histology of the condition, but before dismissing the subject of the electrocardiographic manifestations we would draw attention to certain aspects of this side of the question

The myocardium differs from all other muscular tissue, the common properties of which are irritability, contractility, conductivity, and tonicity, by showing a differentiation of these various functions by their special development in certain of its parts Irritability is predominant in the auricles and determines the origin of the beat, contractility in the walls of the cardiac chambers generally, particularly those of the ventricles, and in the papillary muscles, conductivity has become largely allocated to a special system, the auriculo-ventricular bundle of His, while tonicity, although like these others a property of the cardiac musculature generally, is especially developed in the region of the valve rings so that these may be regarded as modified sphincters, which normally keep the valves competent

Electrocardiographic Evidence

The electrical changes produced during a cardiac cycle are modified by damage to any part of the myocardium, probably in a manner comparable with their modification in injured skeletal muscle, which, as is well known, becomes electro-negative to healthy muscle

Owing to this differentiation of function in the myocardium the physical signs and electrical manifestations of damage to it differ with the part affected

Clinical and Laboratory Notes.

DIABETES INSIPIDUS

OCCURRING IN A CASE OF LYMPHATIC LEUKÆMIA OF ALEUKÆMIC TYPE

By J. H. Sheldon, M.D., M.R.C.P. Lond.,
HONORARY PHYSICIAN, WOLVERHAMPTON AND STAFFORDSHIRE HOSPITAL.

Beyond a casual statement by Schmorl[1] in the course of a discussion, that the pituitary, and especially its anterior lobe, can be affected by leukæmic infiltration like the other organs of the body, there is almost complete absence in the literature of any references to infiltration of the pituitary in leukæmia. I can find no instance recorded of the association of lymphatic leukæmia, infiltration of the pituitary, and diabetes insipidus, such as occurred in the following case.

S. L., male, aged 20, was admitted to hospital on July 27th, 1923, as a suspected case of diphtheria, both tonsils being swollen and covered with patches of white exudate. He had been in perfect health till two years previously, when he noticed that the inguinal glands were swollen, though they caused him no trouble. After this the glands used to swell to a "considerable size" and then diminish again, but he thought so little of them that he never troubled to seek advice. This state of affairs continued for some 23 months, when on June 23rd, 1923, he left off work, owing to a swelling in the left side of the neck, presumably due to enlarged glands. Soon after this the glands on the right side also became enlarged and caused difficulty in swallowing. At the same time a rash appeared. Fourteen days before admission the glands in both axillæ became enlarged. The disease had thus apparently begun in the inguinal glands and remained confined to them for nearly two years before suddenly becoming generalised.

On admission the tongue was very red and raw. Both tonsils, the uvula, and soft palate were injected and swollen. The tonsils were covered with numerous circular patches of white membrane, which were easily stripped off. On culture a streptococcus only was obtained. The skin of the trunk was covered with a large number of firm pink plaques of oval or circular shape. Although pink was the predominant colour, a few had a purplish tint, and with the lapse of time this became true of all. With the exception of two plaques on the forehead the head and limbs were not affected by the eruption. The plaques varied in size from a pea to a half-crown. The glands in both inguinal regions, both axillæ, and both sides of the neck were enlarged, the biggest being of the size of a pigeon's egg.

There was stony dullness under the manubrium, which was regarded as being due to a tumour in the anterior mediastinum. This was confirmed by a skiagram, which Dr. G. E. Dyas kindly took for me.

Blood count on *July 30th, 1923*. Red cells, 4,820,000 per c.mm.; hæmoglobin, 75 per cent.; white cells, 7680 per c.mm.; polymorphonuclears 63 per cent., lymphocytes, 30 per cent., large mononuclears, 3 per cent., eosinophils, 3 per cent.; basophils, 1 per cent. The urine was normal. There was no enlargement of the liver or the spleen and the Wassermann reaction was negative.

Course of the Illness

The throat infection began to clear up after admission and entirely disappeared in a week. On August 3rd it was noted that the glands in the neck were increasing rapidly in size. At their height they reached the size of a bantam's egg, remained like that for a few days and then rapidly subsided. They caused great respiratory distress, but by the end of the month they were only just palpable. As they diminished the glands just above the right clavicle slowly increased in size. These in their turn diminished, and had disappeared by the middle of September. A week later the patient was suffering from cyanosis and great dyspnœa, with great enlargement of all the cervical glands, which had swollen to the size of a duck's egg in the course of three days. They slowly decreased, and by Oct. 5th were again only just palpable. As they waned the inguinal glands waxed, becoming very tender and as big as the cervical glands had lately been. On Oct. 17th the cervical glands again began to swell, and had reached their peak and almost disappeared by Nov. 4th when large glands appeared in the occipital region, remaining till his death five days later.

Blood count on Oct. 11th, 1923, showed: red cells, 3,482,000 per c.mm., hæmoglobin, 55 per cent., white cells, 7840 per c.mm., polymorphonuclears, 41 per cent., lymphocytes, 54 per cent.; large mononuclears, 6 per cent., with no eosinophils or basophils. On Nov. 1st, 1923, a count gave red cells, 3,416,000 per c.mm., hæmoglobin, 55 per cent.; white cells, 12,360 per c.mm., polymorphonuclears, 35 per cent., lymphocytes, 62 per cent., large mononuclears, 3 per cent., and no eosinophils or basophils.

The skin condition remained the same as when first seen until the end of October, when the nodules began to disappear, leaving a faint purplish-brown stain. Death was preceded by an outbreak of purpuric spots on both arms and legs, accompanied by a small epistaxis and three severe attacks of hæmatemesis, in the last of which he died. The temperature was irregular during the last three weeks of life, rising to 101° F.

Polyuria

Polyuria began suddenly on Oct. 26th 1923, the daily amount of urine having been normal until Oct. 24th. On Oct. 25th he complained of great thirst and passed 54 oz. of urine. On the 26th the output of urine rose to 112 oz. and thirst became a very urgent symptom. He was allowed an unrestricted intake of water. The intake of water and the output of urine bore a very close relation to each other, the total intake over the period Oct. 26th to Nov. 8th being 2256 oz., and the total output of urine over the same period being 2076 oz., the respective daily averages being an intake of 160.7 oz. against an output of 148.3 oz. The course of the polyuria is shown in the following table.

A = Intake of fluid in ounces. B = Output of urine in ounces.

Oct	A	B	Oct	A	B	Nov	A	B
25th	?	54	31st	168	160	5th	220	174
26th	166	110	Nov			6th	170	164
27th	192	136	1st	190	154	7th	120	136
28th*	210	206	2nd	140	126	8th	100	100
29th	170	152	3rd	106	98			
30th	180	156	4th	98	104		2250	2076

* On Oct. 28th Pituitrin 0.5 c.cm. twice daily was begun and continued till death.

When first given the pituitrin greatly relieved the condition, but afterwards it had little effect. The variations from day to day were probably more influenced by changes in the amount and locality of the lymphocytic infiltration going on in the pituitary gland. The urine passed over this period had an average specific gravity of 1004, and had no abnormal constituents.

Post-mortem Examination

The *heart* showed a large number of soft yellowish-white spots and streaks, infiltrating the whole myocardium, and visible on both pericardial and endocardial surfaces. Microscopically, these patches consisted of areas of lymphocytic infiltration between the muscle-fibres, which in places were widely separated. The cells consisted almost entirely of small lymphocytes.

The *lungs* were normal to the naked eye, but microscopically there was a general infiltration of the inter-alveolar tissue with small lymphocytes. The bronchial glands were enlarged and connected with a firm white mass which occupied the whole of the anterior mediastinum. This was composed of small round cells, exactly resembling lymphocytes, with a well-developed fibrous stroma. The *spleen* (13 oz.) was hard. Its cut surface was of a uniform dark-red colour, in which it was impossible to distinguish the Malpighian bodies. Microscopically, the splenic pulp was crowded with cells resembling small lymphocytes which had obliterated the Malpighian bodies. The *liver* (60 oz.) was smooth and quite homogeneous, but histologically showed the same general lymphocytic infiltration as the other organs. This was most marked in the portal areas, but in many cases penetrated into the lobules. Both *kidneys* were much enlarged (R. 7½ oz., L. 7¾ oz.) and on section had a mottled appearance, due to numerous yellow patches and streaks, the largest of which were of the size of a halfpenny. The renal tissue between these areas appeared to be quite normal. Microscopically, the kidneys were the subject of a diffuse infiltration with small lymphocytes, which were aggregated in places into patches of wide extent, especially in the neighbourhood of the tubules. The lymphocytic infiltration was heavier in the kidneys than in any other organ.

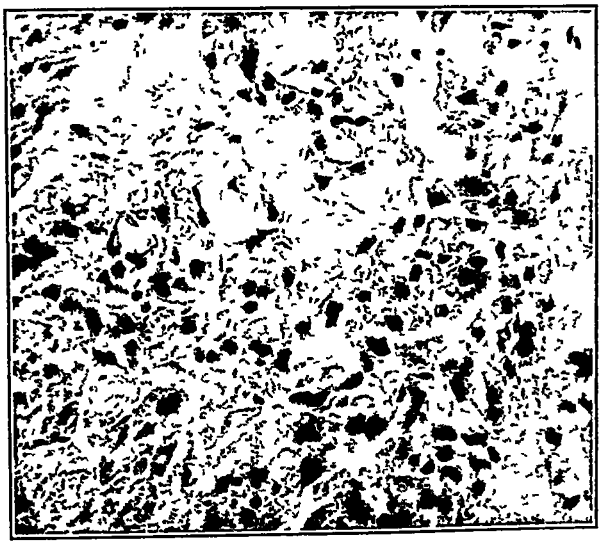
The brain was normal to the naked eye, but was unfortunately not examined microscopically. The *pituitary body* also appeared normal, but microscopically it was affected by the same infiltration with small lymphocytes that has been described in the other organs. This was of a diffuse character and affected all parts of the gland, though the pars anterior was the most heavily burdened, the life the patient had a very fast pulse (absence of damage to a -v. bundle), and that at no time while under observation did auricular fibrillation occur The necrosed muscle bundles seen in these sections recall Zenker's degeneration found typically in the recti abdominales in typhoid fever.

---

[1] Schmorl: Verhandl. d. Deutsch. Path. Gesellsch., 1914, xvii., 231.

It is interesting to note that according to MacCallum, Stejskal and others have described hyaline degeneration or actual necrosis of muscle-fibres scattered throughout the hearts of those dying from sudden collapse at the height of diphtheria, and also in those dying from peritonitis

Fig 4



Microscopic appearance of section of the right ventricle of a woman aged 21 with Graves's disease Magnified 750 diameters Stained with hæmatoxylin and eosin Note the pale areas of necrosed muscle, the swollen nuclei, and the patchy distribution of the areas of necrosis

Pathological Changes

We would summarise the pathological changes as follows —

1 Hyaline degeneration and necrosis of many bundles of fibres scattered throughout the myocardium The necrosed bundles take the stain badly, are swollen, and lack definition The nuclei of some are also swollen

2 A migration of evidently phagocytic cells in the direction of certain of the necrosed fibres no doubt in order to promote their absorption This infiltration, while very marked in places, is absent in others

3 Dilated capillaries choked with endothelial cells which are infiltrating certain necrotic areas in their vicinity

It will be seen that these changes point to a very definite myocardial degeneration, a degeneration so diffuse and extensive that, at first, it looked almost like an infective condition No organisms, however, were discovered in sections especially prepared with Gram's stain

Owing to the courtesy of Dr R W Scarf we have been able to examine sections of the myocardium in another case of fatal thyrotoxicosis, that of a woman of 51 who was being treated by X ray exposures to the thyroid During an application she collapsed and died a few hours afterwards [5] In this case in addition to muscle bundle necrosis similar to but not as marked as in the case of the girl of 21, there was what was absent in the younger case—namely, fragmentation of the ventricular fibres

From such cases we feel justified in concluding that definite myocardial degeneration does occur as the result of prolonged thyrotoxicosis, a conclusion previously reached by us from the clinical and electro cardiographical signs

We are not concerned here with the nature of the toxic thyroid secretion Some years ago McCarrison pointed out that in Graves's disease it was probably altered qualitatively as well as quantitatively, for this reason such terms as dysthyroidic hyperthyroidism (De Quervain), thyrotoxicosis (Kocher), and thyroidism have been introduced and are preferable to the term hyperthyroidism That this secretion produces myocardial degeneration is becoming more and more apparent The morbid histology of the heart in Graves's disease has been drawn attention to by other workers Thus in 1916 Fahr reported destructive lesions of the myocardium in five cases, two in girls of 21 who died from heart failure following partial thyroidectomy, one in a woman of 43, another in a woman of 53, and the fifth in a man of 48 In each case interstitial myocarditis was found, the cardiac muscle-fibres showing degenerative changes with infiltration of leucocytes between them and around the vessels

Since Fahr's report Goodpasture has added two more cases, one a woman of 45, the other a man of the same age, but, as the latter patient was luetic, we are unable to regard this as a pure case of thyrotoxic myocarditis All these cases, with the possible exception of the last support the thesis with which we introduced this paper, that prolonged thyrotoxicosis results in definite myocardial degeneration

If by drawing attention to the existence of thyrotoxic myocarditis and its nature we have also been able to indicate the importance of early and effective treatment of Graves's disease and other forms of thyroidism, we shall be more than gratified, for it will be obvious that the more advanced the changes in the heart muscle the greater the danger of any radical treatment and the less the degree of recovery to be expected therefrom

Before concluding we should like to state how much indebted we are to both Sir Arthur Keith and Sir Bernard Spilsbury for their kindness in carefully examining these sections and encouraging us to record this case

Victoria Infirmary, Glasgow —On Saturday last Sir John Gilmour, Secretary of State for Scotland opened a new wing of this hospital, which includes an extension of the nurses' home

New Hospital Scheme at Liverpool —After five years' preparation a voluntary hospitals contributory scheme was approved at a meeting representative of the Liverpool Hospitals held at Liverpool on Feb 25th The scheme of the Liverpool Voluntary Hospitals Council is "to raise money by voluntary contributions for the support of hospitals and convalescent homes in Liverpool and to distribute the funds so collected in its discretion A special appeal in order to start the fund will be made on June 1st The scheme incorporates the Hospital Saturday and Sunday Funds, but does not apply to subscriptions, donations, or proceeds of social functions, and the like for individual hospitals The constitution of the council was arranged and included in the executive are six representatives each of employers and employees Mr Sydney Lamb of New Wanstead, Essex, was appointed organising officer to the scheme at a salary of £1000 a year Mr Lamb was responsible for the great success of the Sheffield Voluntary Hospitals contributory scheme, upon which the Liverpool scheme is based third degree to the good ear was present. The caloric test was not performed as the patient's condition was poor The mastoid process was slightly tender on the tip; there was no tenderness over the mastoid antrum

---

[5] This case is of particular interest in view of the fact that whereas some years ago one of us (J S G) pointed out that X ray treatment reduced or abolished most of the symptoms of thyrotoxicosis, it appeared to be less effective in arresting myocardial degeneration

From the absence of definite signs and the age of the patient a labyrinthine hæmorrhage was considered as a possible diagnosis yet the tuning-fork tests and the slight pain in the ear decided me to do a paracentesis, which revealed thick yellow pus. The diagnosis of suppurative labyrinthitis was then made and it was resolved to operate.

The *operation* revealed a small quantity of thin muco-pus in a cancellous mastoid The lateral sinus was white On incision the sinus was empty, exposure far back towards the *torcula* revealed blood. On removing the bone anterior to the lateral sinus pus exuded from the bone and on further exposure an abscess in the cerebellum with a well-formed wall was found A tube was inserted in this cavity and the Neuman's labyrinth operation was performed. The patient was in excellent condition on Jan 8th, but on the 9th the temperature rose and the patient became comatose and died

The remarkable features of this case were the dresence of the light reflex and an almost normal tympanic membrane with mastoiditis, lateral sinus thrombosis and cerebellar abscess The infection evidently started in the mastoid and secondarily involved the middle ear Furthermore the case is remarkable in that symptoms directed the patient's doctor's attention to the abdomen, the presence of nystagmus being the only prominent aural sign for both tympanic membranes had to be examined before one was convinced that the right was abnormal As there was no history of trauma to the mastoid, which would make the region a *locus minoris resistentiæ* for organisms circulating in the blood, one must conclude that the infecting agent was brought directly into the antrum by the blood or through the Eustachian tube into the antrum without infection of the tympanic cavity Such an infection is usually due to the *Streptococcus mucosus*, which gives a picture on the tympanic membrane like that of chronic catarrh and is sometimes treated for that with disastrous results

The condition also reminds one of acute mastoiditis which develops in children after an attack of diarrhœa. In such cases the tympanic membrane is not ruptured and is white, the only abnormality present on the tympanic membrane being an absence of the light reflex

Darlington

Medical Societies.

MEDICO-LEGAL SOCIETY.

A meeting of this Society was held on Feb 24th, Sir William Willcox in the chair, when Dr. Frederick J. McCann read a paper on

Cases of Medico-legal Interest in the Practice of Gynæcology

Dealing first with virginity and defloration, Dr McCann said that on medical evidence alone it was difficult, and sometimes impossible, to establish the fact that a woman was a virgo intacta. Mr. D. Cotes-Preedy had stated that "the presence of a hymen is generally received by the court as sufficient evidence of the accused being a virgo intacta" But the presence of an unruptured hymen was not absolute proof of virginity, nor did a torn hymen prove that a woman was not a virgo intacta; it was often impossible to be sure unless the vulva was seen soon after the attempt, before the torn surfaces could unite A young woman arrested for loitering and prostitution was examined and found to have a well-developed semilunar hymen, thin, and readily distensible In the centre was a small notch, and leading backwards from the notch was a tiny white scar, indicating that there had been a partial tear in this position, which had healed. He could not report that she was a virgo intacta, but said that she did not seem to have had repeated intercourse Too often the hymen was torn during examinations without considering consequences and the pelvic organs of virgins should be examined per rectum wherever possible If the hymen had been injured it should be repaired by accurate suture with fine catgut Signs of virginity were sought in the hymen, fourchette, perineum, and vagina The breasts gave no guidance, for even milk might be present in the virginal breast infants sometimes being put to the breasts of a virgin Sometimes a hymen had a vertical opening, and the inexperienced might consider that this was a rupture What was of most importance in legal medicine was the texture and consistence of the hymen A thin elastic membrane was not easily ruptured; if ruptured it bled little, and it could be pushed upwards by the male and satisfactory coitus ensue without rupture Kanony had collected records of 43 cases of pregnancy in which the hymen remained unruptured. Coitus did not destroy the hymen, it only ruptured it in one or more places In some cases the texture of the hymen was such that it was readily torn and bled freely; sometimes it had to be divided to permit of coitus Much had been made in the courts of the possibility that the hymen might be absent from birth, but he had never encountered such a case It might, however, be so altered by inflammation or injury that signs of virginity could not be determined.

The exanthemata and diphtheria had a great influence on the generative organs of the female child; inflammation might even result in an imperforate hymen or an imperforate vagina The effect of masturbation was usually a dilatation of the hymeneal orifice, without evidence of rupture The fourchette and the perineum might be torn by violent intercourse, or when the diameter of the penis was out of proportion to the aperture. The absence of such injury was no proof of virginity. No reliance could be placed on the absence of rugosity in the vaginal walls as a sign that penetration had occurred All the signs of virginity might be present in a woman who was not a virgin, and all those signs might be absent in a virgin He had been called to a woman, aged 60 who had advanced abdominal cancer. Her first husband had been impotent and had so remained until his death, and her second marriage had never been consummated Her hymen was tough and resistant with a small central opening He considered she was a virgo intacta despite 30 years of married life Another woman, married eight years, had never had connexion Both these women seemed very ignorant of sexual matters. In all cases of a difficult kind he suggested that an expert in gynæcology should be consulted

Turning next to the consideration of rape, Dr. McCann said medical men not infrequently became the dupes of designing females through accepting statements which were not justified It was not always possible to say whether the female sexual organs had suffered violence by the male or by other physical means To come to the definition of rape penetration to the vulva was said to be sufficient In a recent case in which there was neither defloration nor signs of violence nor the presence of spermatozoa such a charge could not be sustained on medical evidence alone. The phrase "penetration to the vulva" was meaningless in the case of the child, because in the very young child the hymen projected beyond the level of the surrounding parts In legal medicine the differences between the female child and the adult were often ignored In adult females, unless defloration violence, or the deposition of semen could be proved, the charge could not be sustained on medical grounds In some of the cases which had come to his notice false charges had been made against men because of the existence of a purulent discharge in children A purulent discharge from a child's vulva was not sufficient ground for a criminal charge; there might be an organism lymphocytes in this region showing a tendency to accumulate in small masses

The *lymphatic structures* throughout the body were greatly enlarged In the intestines the Peyer's patches and solitary nodules were swollen The lymphatic glands were enlarged in varying degrees, though all groups were affected Histologically, in the smaller glands the normal structure could still be made out, though obscured by a general packing with small lymphocytes which in the larger glands had completely obliterated their structure A section of one of the cutaneous nodules revealed a large irregular collection of lymphocytes, gathered especially round the hair follicles and sweat glands, and lying under the epidermis, which was intact Bone-marrow was taken from the lower third of the femur The normal hæmopoietic cells were recognisable, but the marrow was very cellular owing to a diffuse packing with lymphocytes

Discussion

There can be no doubt that this case was one of lymphatic leukæmia of the aleukæmic type, having a general lymphocytic infiltration of all the organs without the typical blood changes Apart from the polyuria, the case is very similar to one reported by Blankenhorn and Goldblatt [2] The disease apparently remained confined to the inguinal glands for two years and then suddenly became generalised It is possible that the typical blood picture of lymphatic leukæmia might have come later, as there was a progressive anæmia, and the total white cells had increased while under observation from 7680 per c mm to 12,360 per c mm the percentage of lymphocytes rising from 30 to 62 per cent This gives an increase in the actual number of lymphocytes of from 2304 per c mm to 7663 per c mm

The sudden onset of the polyuria is interesting, the urinary output rising in one day from 54 oz to 110 oz. This may have been caused by a sudden infiltration of the pituitary, and certainly a rapid infiltration would be in keeping with the rest of the clinical picture. Thus the lymphatic glands were continually subject to periodic alterations of size, usually slowly, but on some occasions reaching a maximum in three days The association of diabetes insipidus with lesions of the pituitary is well known, the pars anterior being as a rule either not affected or only partially damaged In the present case an accurate geographical description of the pituitary lesion cannot be given, the infiltration being of a diffuse character

Summary

1 A case of aleukæmic leukæmia is described, with general lymphocytic infiltration of the organs, but without typical blood changes 2. Death was preceded by a sudden attack of diabetes insipidus, with considerable daily variation in severity, and associated with lymphocytic infiltration of the pituitary gland

---

A CASE OF
MULTIPLE ANEURYSMS OF THE SPLENIC ARTERY

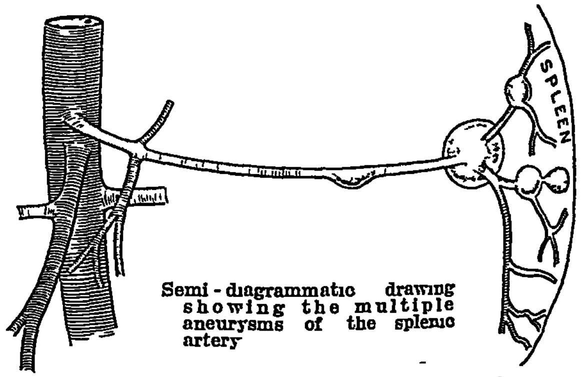
BY J ALLAN BERRY, M S DURH, F R C S EDIN,
MEDICAL SUPERINTENDENT, NAPIER HOSPITAL, N Z

ONLY a few cases of aneurysm of the splenic artery are mentioned in the literature, and owing to its rarity the present instance seems worthy of record

The patient, a thin spare woman, aged about 60, was admitted to the Napier hospital on Nov 4th, 1922, suffering from jaundice of about nine weeks' duration Previous to the onset of the jaundice there was no history of indigestion, but since its appearance there had been pain in the epigastrium shortly after meals, associated with vomiting On examination the patient was deeply jaundiced and a tender mass could be palpated in the gall-bladder X ray examination showed the presence of stones in the gall-bladder, and a barium meal showed the stomach to be normal There was no sugar in the urine and the Loewi test was negative

On Nov 17th an exploratory laparotomy was performed There was very little hæmorrhage at the operation, hæmostatic serum having been administered previously The gall-bladder was full of stones and was removed, and the common bile-duct drained Masses of glands were noted in the gastro-hepatic omentum. A microscopical examination of the gall-bladder demonstrated a carcinoma of its neck. Following the operation the patient's condition remained satisfactory until signs of cerebral embolism appeared and she died half an hour later

A limited post-mortem examination was made through the operation wound Hard masses of glands were found surrounding the supra-duodenal portion of the common bile-duct, and secondary deposits were present in the liver



Semi-diagrammatic drawing showing the multiple aneurysms of the splenic artery

The heart showed no signs of endocarditis, and there was very little atheroma of the thoracic aorta. The splenic artery was found to be the site of multiple aneurysms so that part of the abdominal aorta, with the vessels of the cœliac axis and the spleen, was removed

The accompanying diagram shows an abnormal arrangement of the cœliac axis and also shows the aneurysms About an inch before the splenic artery divided into its branches is a slight dilatation of the lower part of its circumference, while at the point of bifurcation is an aneurysm roughly circular in outline, about an inch in diameter, and having calcified walls Leading from this aneurysm are two vessels, on the superior branch after a course of about two inches is another aneurysm with calcified walls less than half an inch in diameter On the superior division of the two into which the inferior trunk divides are two more calcified aneurysms, one springing from the other, each a little less than half an inch in diameter

The X ray films did not show the shadows due to the calcified walls of the aneurysm, one showed the shadow due to the gall-stones, while the other, of a barium meal of the stomach, obliterated any shadows that might have been due to them

One of the latest cases on record is that of Hogler,[1] who reports a case which he thinks is the only one in which a correct diagnosis was made during life The symptoms were severe spinal pain with the development of a pulsating swelling in the left hypochondrium, over which a systolic bruit was heard The patient died of intercurrent pancreatic cancer

CEREBELLAR ABSCESS IN AN ELDERLY WOMAN.

BY W S THACKER-NEVILLE, M D DUB,
F R C S EDIN,
OPHTHALMOLOGIST AND LARYNGOLOGIST, DARLINGTON GENERAL HOSPITAL.

THE case here described presented certain features of unusual interest

Mrs P, aged 71, had been treated as an abdominal case for some time She complained of earache in September, 1926, but recovered in a short time At the commencement of December she developed symptoms that were looked upon as having their origin in the abdomen

On *examination* on Jan 7th last I found the patient lying on her left side She complained of pain about her right ear and dizziness and vomiting if she moved, the vomiting being the most prominent symptom. The tympanic membrane showed a light reflex bright but shortened, and in the posterior superior quadrant a salmon-pink patch, like the centre patch seen in otosclerosis The tuning-fork tests showed middle-ear involvement Nystagmus of the

the scientific evidence often was not given calm consideration

Dr. MCCANN, in a brief reply, pointed out how important in these cases was the evidence of the medical man who first saw the victim Unless the child was seen fairly soon, healing of the hymen took place. Puberty was the earliest period at which vulval penetration was possible, unless there was precocious development of the sexual organs

ROYAL SOCIETY OF MEDICINE

SECTIONS OF MEDICINE AND DISEASES OF CHILDREN

A JOINT meeting of these Sections was held on Feb 25th, the chair being occupied by Dr J D ROLLESTON, President of the Section of Children's Diseases

Dr E W. GOODALL opened a discussion on

THE SERUM TREATMENT OF SCARLET FEVER

He began by explaining that before he had formed a conclusion as to the efficacy of the treatment he had ceased to have first-hand opportunities for testing it He assumed that the hæmolytic streptococcus of George and Gladys Dick was the true bacterial cause of the disease Since 1910 the case mortality for scarlet fever in the Metropolitan Asylums Board hospitals had only once been above 2 per cent —namely, in 1910 During the ten years that he had been at the North-Western Fever Hospital it was quite low, and in 1925 it was 1 01 per cent Hence in the matter of the saving of life there was little room for further improvement In most cases of diphtheria the condition was a toxæmia pure and simple, whereas in scarlet fever there was also bacteræmia It was not claimed he believed, that the scarlatinal antiserum was antibacterial as well as antitoxic The following points should be considered · (1) Was serum treatment better than any other ? (2) If so, how was this shown ? (3) Did the results make it possible to distinguish between the toxæmic and the septic symptoms ? (4) What was the correct dosage ? In some cities in the United States in recent years, there had been a comparatively high death-rate from scarlet fever In Eastern Europe and China the disease had recently been very severe At the Government Isolation Hospital at Pekin serum had been found of little value in the toxic form of the disease, though later a serum produced by a different method had been of some use Cushing, at the Alexandra Hospital, Montreal, had reported improvement after the use of convalescent serum for serious cases, and a number of observers had reported that it hastened the disappearance of symptoms The earlier the remedy was given the better and surer was the result ; it could hardly be expected to do much if given later than the fifth day. Of 56 patients to whom he had given this treatment four had died, but none from the uncomplicated disease Forty-one of the patients had received the serum in the first three days of their illness A study of these cases gave him the impression that a *prima facie* case had been made out in favour of the serum Twenty-four of the patients had attacks of serum sickness, but only one of these was severe , one had an abscess at the site of the injection Long ago he had seen good results in the disease from the use of a multivalent serum, probably from accidental presence of special hæmolytic streptococcus in the mixture The unit-dosage system of administration had not been adopted in this country, as the methods of standardising the toxin and serum had not been satisfactory In the United States the dosage was from 2000 to 10,000 units

Discussion

Dr. R A O'BRIEN said that he had only limited opportunities for judging clinically of the effects of the serum He had, therefore, obtained the views of the superintendents of several hospitals outside London, especially in the North, where the disease seemed to be of a more severe type Dr W T Benson, of the City Hospital, Edinburgh, concluded that the administration of antitoxic serum in the first 48 hours of the disease had a very favourable influence on the specific toxæmia of scarlet fever ; it relieved the more urgent symptoms of the acute stage, and seemed to reduce complications It did not seem to be an absolute safeguard against septic complications in convalescence In toxic cases the serum should be used either intravenously or subcutaneously at the earliest opportunity, and the dose should be repeated if necessary Dr Benson had treated 200 or 300 cases with the English concentrated serum, the usual dose being 10 c cm , 20 c cm was rarely required Serum rashes were troublesome Dr Benson was not, however, prepared to discharge his patients in the third week of convalescence because they had had the serum Dr. E H R Harries had informed him that for eight months the concentrated antitoxin had been used at the City Hospital, Birmingham, for all cases except the mildest Serum sickness was infrequent, and when it did occur it was but trifling In the average case a dose of 10 c cm sufficed

In Dr O'Brien's view the problem of scarlet fever was one of late morbidity. It was impossible to foretell what complications a patient with a mild attack might develop in the second or third week He did not find that the serum had any direct influence on the septic complications of the disease, but he would not feel justified in withholding serum from a severe case He had never known a child contract scarlet fever after having been rendered Dick-negative by antitoxin, even if repeatedly exposed to infection Dr O'Brien said that Dr Claude Rundle, of the Liverpool City Hospital, had used serum in about 100 cases, and there had been five deaths His opinion was that many of the patients would have died if they had not had the treatment All except one of the deaths were of patients with scarlet fever of the septic type who came under treatment late.

Dr F FOORD CAIGER said that he had not had the opportunity of trying the serum treatment as much as he would have liked, but the results following its use did not seem so far to have been very much better than those of earlier workers , the Warsaw results in 1894 had led to very great hopes for the future It was scarcely to be expected that the Dick serum alone would do much in the septic form of the disease He referred to the success of a multivalent serum for scarlet fever which was sent to him about 30 years ago by Prof A Besredka from Paris It was derived from 20 strains of scarlatinal cocci It was given to 44 patients who seemed sure to die, and the ultimate mortality amongst them was 36 per cent In the severe cases, in which it was given on the fourth or fifth day, the mortality was 23 per cent , of the patients who had it two days later 25 per cent died and amongst those who did not have it until the ninth day the mortality was 56 per cent.

The CHAIRMAN said that the case mortality from scarlet fever from 1874–79 was 13 9 per cent —exactly the rate given for Warsaw during the first 26 weeks of 1926 During the years following 1879 there had been a gradual fall in the mortality, so that in 1900 it was 3 per cent , and in the last report of the Metropolitan Asylums Board it had come down to 1 1 The disease was also mild in France, but in the north it seemed to be of a much more severe type He agreed that it was unnecessary to give serum to all patients with scarlet fever, especially as it might render them hypersensitive for a number of years He had, therefore, tried the treatment in only 60 cases These he divided into three classes (*a*) 23 cases in which benefit was marked and immediate , (*b*) 24 cases showing definite benefit from it , and (*c*) 13 in which no benefit followed, amongst which five deaths occurred Serum rash appeared in 26 cases, and in nine there was pyrexia, some constitutional disturbance, and secondary adenitis The doses varied from 10 c cm to 30 or 40 c cm and they were seldom repeated The Chairman raised the question whether earlier discharge of those cases which had the serum was closely resembling the gonococcus which had no relation to the disease. He thought that the law in relation to rape needed clearer definition; it did not keep pace with the advances in science. In most cases of alleged rape the charge should be one of indecent assault. The term "rape" should be restricted to cases in which penetration had been proved, or where considerable local injury had followed attempts at penetration.

Dealing with nubility, impotence, and sterility, Dr. McCann said that the law seemed to regard the female as a mere passive agent in the sexual act. He suggested that a nubile or marriageable woman was one whose sexual organs were normally developed or were without irremediable defect. The menstrual function was ignored in these words, for it could often be restored when absent. In one case both husband and wife seemed well developed but the marriage had not been consummated, and the judge pronounced a decree of nullity. Here a judicial warning would probably have had a salutary effect; sometimes friendly advice by the family doctor would obviate a judicial appeal later on. Impotence Dr McCann would define as the failure of the power to copulate, or failure of the power to generate. Both might be present in the same individual. The failure to distinguish between these two struck at the root of the confusion on the subject in legal medicine. Sometimes a decree of nullity had been obtained against a male by a female, and subsequently that male had become the father of a family. Works on legal medicine too frequently overlooked the psychical influence in sexual desire; it explained some cases of impotence, at least temporary impotence. Sometimes owing to male impotence methods of sexual excitation had been employed which had had an injurious effect on the nervous system of the female. Impotence he regarded as much more common in the female than in the male; yet the woman was regarded as the mere passive agent, and if her vagina would admit penetration, she would not succeed in a nullity suit. As to sterility, generative incapacity on the part of the female rarely came before the courts, perhaps because of difficulty in establishing its existence. A woman with normal sexual organs might be successfully impregnated by one man and fail with another. He was sure that a slightly undersized uterus would carry a fœtus successfully to the end of gestation.

A young woman engaged to be married consulted him because she had never menstruated. She had an imperforate vagina and no uterus could be detected. Her fiancé urged that a segment of the small intestine should be transplanted into the region of the vagina to produce an artificial vagina. Dr McCann advised against such an operation as it was dangerous and unjustifiable, and urged giving up the idea of marriage. She consulted another surgeon, who performed the operation, and it proved fatal.

Going on to speak of venereal disease and divorce, Dr McCann said it was very necessary that the doctor who was first consulted should make a thorough examination of his patient, male or female, or consult with an expert without loss of time, as it might be difficult, even impossible, to obtain evidence at a later date. To establish the diagnosis of gonorrhœa in the female it was essential that secretion should be obtained for examination from the urethra, from the glands of Bartholin, or from the cervix uteri. Secretion from the vagina for this purpose was useless. Yet in a recent case smears taken from the vagina were offered as evidence. In order to detect the gonococcus, a sterilised platinum needle should be used to obtain specimens for microscopical examination, as well as to inoculate the culture medium. The science of bacteriology had not yet reached the degree of perfection which enabled a medical man to make positive assertions in the witness-box; he could only show that he had investigated a particular case with every care. The same applied to the diagnosis of syphilis.

Removal of both ovaries in a young woman might be followed, in the course of years, by such shrinking of the vagina that, in the event of her subsequent marriage, sexual intercourse might become difficult or impossible. Hysterectomy did not always banish sexual desire, but it interfered with sexual pleasure, for without a uterus there could be no orgasm. The question of operations on the female genitalia after marriage was an important one. If a woman who had undergone hysterectomy married without telling her future husband the nature of the operation she had undergone, could the man obtain a decree of nullity? A man who married a woman pregnant by another man could not obtain relief. Dr McCann thought that the law should be altered to include the cases where the knowledge of a mutilating operation or the existence of pregnancy by another male was withheld. Many operations, moreover, left psychical effects of far-reaching importance, and this aspect would demand more attention in the future, as it loomed large in the patient's mental horizon.

Discussion

Dr M. I. FINUCANE agreed that the legal test as to whether a woman was a virgo intacta was a ridiculous one from the doctor's point of view.

Sir TRAVERS HUMPHREYS said that he was not aware that the law required that in order to justify a conviction for rape there should have been penetration of the vulva. Judges said that such a charge could not hold unless there had been some penetration, and left the matter there. He did not think that lawyers would quarrel with a doctor because he could not be quite sure whether a particular woman was a virgo intacta. He had been glad to note the careful way in which most medical witnesses gave their evidence in court, and the fact that they did not attempt to dogmatise was in their favour. A woman could be convicted of procuring a girl to become a prostitute even though the girl might be a virgo intacta. And a prostitute meant a female who, for money, gave her body to men for indecent practices, which did not necessarily include copulation.

Sir BERNARD SPILSBURY expressed his agreement with what Sir Travers Humphreys had said on the subject of penetration; he had always conceived that what was meant was some degree of penetration, not necessarily vulval. He asked at what age vulval penetration was said to be possible; did it date from puberty, or was there a period antecedent to that when it was possible? He agreed with what Dr McCann had said about diagnosis of gonorrhœa in the female. It was difficult to get medical men to take those precautions which would enable pathologists to carry out a proper bacteriological examination. In suspected gonococcal infection of the female genital organs, evidence should not be given without complete bacteriological proof, in cultures as well as smears from any discharge. The difficulty was even greater in the dead body, when the gonococcus had died. He related a case in which, in a female child, gonorrhœa was suspected because of a vaginal discharge, and it was proved that the discharge was due to a long antecedent inflammation caused by a thread-worm. He hoped soon to lay before the Society the result of some investigations he had been making on a means of distinguishing between congenital conditions and those which were the result of injury. The elastic tissue of the skin was not re-formed after an injury had been sustained sufficient to cause a scar.

Mr W. G. EARENGEY did not agree with those who asked for another definition of rape for legal purposes. The doctor could tell whether violence had been used in a given case, especially as most of the cases came before the doctor soon after the alleged attempts. And he did not think that judges were far behind the advances of science.

The CHAIRMAN thought that there was no great difficulty in deciding about penetration; usually there was a good deal of local evidence of violence. An important point was that these cases of attempted rape were surrounded by such a feeling of horror that the scientific evidence often was not given calm consideration.

Dr McCANN, in a brief reply, pointed out how important in these cases was the evidence of the medical man who first saw the victim Unless the child was seen fairly soon, healing of the hymen took place. Puberty was the earliest period at which vulval penetration was possible, unless there was precocious development of the sexual organs

ROYAL SOCIETY OF MEDICINE.

SECTIONS OF MEDICINE AND DISEASES OF CHILDREN.

A JOINT meeting of these Sections was held on Feb 25th the chair being occupied by Dr. J. D ROLLESTON, President of the Section of Children's Diseases

Dr E W GOODALL *opened a discussion on*

THE SERUM TREATMENT OF SCARLET FEVER.

He began by explaining that before he had formed a conclusion as to the efficacy of the treatment he had ceased to have first-hand opportunities for testing it He assumed that the hæmolytic streptococcus of George and Gladys Dick was the true bacterial cause of the disease Since 1910 the case mortality for scarlet fever in the Metropolitan Asylums Board hospitals had only once been above 2 per cent —namely, in 1916 During the ten years that he had been at the North-Western Fever Hospital it was quite low, and in 1925 it was 1 01 per cent Hence in the matter of the saving of life there was little room for further improvement In most cases of diphtheria the condition was a toxæmia pure and simple, whereas in scarlet fever there was also bacteræmia. It was not claimed he believed, that the scarlatinal antiserum was antibacterial as well as antitoxic. The following points should be considered: (1) Was serum treatment better than any other? (2) If so, how was this shown? (3) Did the results make it possible to distinguish between the toxæmic and the septic symptoms? (4) What was the correct dosage? In some cities in the United States in recent years, there had been a comparatively high death-rate from scarlet fever. In Eastern Europe and China the disease had recently been very severe. At the Government Isolation Hospital at Pekin serum had been found of little value in the toxic form of the disease, though later a serum produced by a different method had been of some use. Cushing, at the Alexandra Hospital, Montreal, had reported improvement after the use of convalescent serum for serious cases, and a number of observers had reported that it hastened the disappearance of symptoms The earlier the remedy was given the better and surer was the result, it could hardly be expected to do much if given later than the fifth day Of 56 patients to whom he had given this treatment four had died but none from the uncomplicated disease Forty-one of the patients had received the serum in the first three days of their illness A study of these cases gave him the impression that a prima facie case had been made out in favour of the serum Twenty-four of the patients had attacks of serum sickness, but only one of these was severe; one had an abscess at the site of the injection Long ago he had seen good results in the disease from the use of a multivalent serum, probably from accidental presence of special hæmolytic streptococcus in the mixture The unit-dosage system of administration had not been adopted in this country, as the methods of standardising the toxin and serum had not been satisfactory In the United States the dosage was from 2000 to 10,000 units

Discussion.

Dr R A O'BRIEN said that he had only limited opportunities for judging clinically of the effects of the serum. He had therefore, obtained the views of the superintendents of several hospitals outside London, especially in the North, where the disease seemed to be of a more severe type Dr. W T. Benson, of the City Hospital Edinburgh, concluded that the administration of antitoxic serum in the first 48 hours of the disease had a very favourable influence on the specific toxæmia of scarlet fever; it relieved the more urgent symptoms of the acute stage and seemed to reduce complications It did not seem to be an absolute safeguard against septic complications in convalescence. In toxic cases the serum should be used either intravenously or subcutaneously at the earliest opportunity, and the dose should be repeated if necessary Dr Benson had treated 200 or 300 cases with the English concentrated serum, the usual dose being 10 c cm ; 20 c cm. was rarely required. Serum rashes were troublesome Dr. Benson was not, however, prepared to discharge his patients in the third week of convalescence because they had had the serum. Dr E H R Harries had informed him that for eight months the concentrated antitoxin had been used at the City Hospital Birmingham, for all cases except the mildest. Serum sickness was infrequent, and when it did occur it was but trifling. In the average case a dose of 10 c cm sufficed

In Dr. O'Brien's view the problem of scarlet fever was one of late morbidity. It was impossible to foretell what complications a patient with a mild attack might develop in the second or third week He did not find that the serum had any direct influence on the septic complications of the disease, but he would not feel justified in withholding serum from a severe case He had never known a child contract scarlet fever after having been rendered Dick-negative by antitoxin even if repeatedly exposed to infection. Dr. O'Brien said that Dr Claude Rundle, of the Liverpool City Hospital had used serum in about 100 cases, and there had been five deaths. His opinion was that many of the patients would have died if they had not had the treatment. All except one of the deaths were of patients with scarlet fever of the septic type who came under treatment late.

Dr. F. FOORD CAIGER said that he had not had the opportunity of trying the serum treatment as much as he would have liked but the results following its use did not seem so far to have been very much better than those of earlier workers: the Warsaw results in 1894 had led to very great hopes for the future. It was scarcely to be expected that the Dick serum alone would do much in the septic form of the disease He referred to the success of a multivalent serum for scarlet fever which was sent to him about 30 years ago by Prof A Besredka from Paris It was derived from 20 strains of scarlatinal cocci It was given to 44 patients who seemed sure to die and the ultimate mortality amongst them was 36 per cent In the severe cases, in which it was given on the fourth or fifth day, the mortality was 23 per cent ; of the patients who had it two days later 25 per cent died, and amongst those who did not have it until the ninth day the mortality was 56 per cent.

The CHAIRMAN said that the case mortality from scarlet fever from 1874–79 was 13 9 per cent —exactly the rate given for Warsaw during the first 26 weeks of 1926 During the years following 1879 there had been a gradual fall in the mortality so that in 1900 it was 3 per cent, and in the last report of the Metropolitan Asylums Board it had come down to 1·1 The disease was also mild in France but in the north it seemed to be of a much more severe type. He agreed that it was unnecessary to give serum to all patients with scarlet fever especially as it might render them hypersensitive for a number of years He had, therefore, tried the treatment in only 60 cases These he divided into three classes: (a) 23 cases in which benefit was marked and immediate; (b) 24 cases showing definite benefit from it; and (c) 13 in which no benefit followed, amongst which five deaths occurred. Serum rash appeared in 26 cases, and in nine there was pyrexia, some constitutional disturbance, and secondary adenitis The doses varied from 10 c.cm. to 30 or 40 c cm, and they were seldom repeated. The Chairman raised the question whether earlier discharge of those cases which had the serum was closely resembling the gonococcus which had no relation to the disease. He thought that the law in relation to rape needed clearer definition, it did not keep pace with the advances in science. In most cases of alleged rape the charge should be one of indecent assault. The term "rape" should be restricted to cases in which penetration had been proved, or where considerable local injury had followed attempts at penetration.

Dealing with nubility, impotence, and sterility, Dr McCann said that the law seemed to regard the female as a mere passive agent in the sexual act. He suggested that a nubile or marriageable woman was one whose sexual organs were normally developed or were without irremediable defect. The menstrual function was ignored in these words, for it could often be restored when absent. In one case both husband and wife seemed well developed but the marriage had not been consummated, and the judge pronounced a decree of nullity. Here a judicial warning would probably have had a salutary effect; sometimes friendly advice by the family doctor would obviate a judicial appeal later on. Impotence Dr McCann would define as the failure of the power to copulate, or failure of the power to generate. Both might be present in the same individual. The failure to distinguish between these two struck at the root of the confusion on the subject in legal medicine. Sometimes a decree of nullity had been obtained against a male by a female, and subsequently that male had become the father of a family. Works on legal medicine too frequently overlooked the psychical influence in sexual desire, it explained some cases of impotence, at least temporary impotence. Sometimes owing to male impotence methods of sexual excitation had been employed which had had an injurious effect on the nervous system of the female. Impotence he regarded as much more common in the female than in the male, yet the woman was regarded as the mere passive agent, and if her vagina would admit penetration, she would not succeed in a nullity suit. As to sterility, generative incapacity on the part of the female rarely came before the courts, perhaps because of difficulty in establishing its existence. A woman with normal sexual organs might be successfully impregnated by one man and fail with another. He was sure that a slightly undersized uterus would carry a fœtus successfully to the end of gestation.

A young woman engaged to be married consulted him because she had never menstruated. She had an imperforate vagina and no uterus could be detected. Her fiance urged that a segment of the small intestine should be transplanted into the region of the vagina to produce an artificial vagina. Dr McCann advised against such an operation as it was dangerous and unjustifiable, and urged giving up the idea of marriage. She consulted another surgeon, who performed the operation, and it proved fatal.

Going on to speak of venereal disease and divorce, Dr McCann said it was very necessary that the doctor who was first consulted should make a thorough examination of his patient, male or female, or consult with an expert without loss of time, as it might be difficult, even impossible, to obtain evidence at a later date. To establish the diagnosis of gonorrhœa in the female it was essential that secretion should be obtained for examination from the urethra, from the glands of Bartholin, or from the cervix uteri. Secretion from the vagina for this purpose was useless. Yet in a recent case smears taken from the vagina were offered as evidence. In order to detect the gonococcus, a sterilised platinum needle should be used to obtain specimens for microscopical examination, as well as to inoculate the culture medium. The science of bacteriology had not yet reached the degree of perfection which enabled a medical man to make positive assertions in the witness-box; he could only show that he had investigated a particular case with every care. The same applied to the diagnosis of syphilis.

Removal of both ovaries in a young woman might be followed, in the course of years, by such shrinking of the vagina that, in the event of her subsequent marriage, sexual intercourse might become difficult or impossible. Hysterectomy did not always banish sexual desire, but it interfered with sexual pleasure, for without a uterus there could be no orgasm. The question of operations on the female genitalia after marriage was an important one. If a woman who had undergone hysterectomy married without telling her future husband the nature of the operation she had undergone, could the man obtain a decree of nullity? A man who married a woman pregnant by another man could not obtain relief. Dr McCann thought that the law should be altered to include the cases where the knowledge of a mutilating operation or the existence of pregnancy by another male was withheld. Many operations, moreover, left psychical effects of far-reaching importance, and this aspect would demand more attention in the future, as it loomed large in the patient's mental horizon.

Discussion

Dr **M. I. Finucane** agreed that the legal test as to whether a woman was a virgo intacta was a ridiculous one from the doctor's point of view.

Sir **Travers Humphreys** said that he was not aware that the law required that in order to justify a conviction for rape there should have been penetration of the vulva. Judges said that such a charge could not hold unless there had been some penetration, and left the matter there. He did not think that lawyers would quarrel with a doctor because he could not be quite sure whether a particular woman was a virgo intacta. He had been glad to note the careful way in which most medical witnesses gave their evidence in court, and the fact that they did not attempt to dogmatise was in their favour. A woman could be convicted of procuring a girl to become a prostitute even though the girl might be a virgo intacta. And a prostitute meant a female who, for money, gave her body to men for indecent practices, which did not necessarily include copulation.

Sir **Bernard Spilsbury** expressed his agreement with what Sir Travers Humphreys had said on the subject of penetration; he had always conceived that what was meant was some degree of penetration, not necessarily vulval. He asked at what age vulval penetration was said to be possible; did it date from puberty, or was there a period antecedent to that when it was possible? He agreed with what Dr McCann had said about diagnosis of gonorrhœa in the female. It was difficult to get medical men to take those precautions which would enable pathologists to carry out a proper bacteriological examination. In suspected gonococcal infection of the female genital organs, evidence should not be given without complete bacteriological proof, in cultures as well as smears from any discharge. The difficulty was even greater in the dead body, when the gonococcus had died. He related a case in which, in a female child, gonorrhœa was suspected because of a vaginal discharge, and it was proved that the discharge was due to a long antecedent inflammation caused by a thread-worm. He hoped soon to lay before the Society the result of some investigations he had been making on a means of distinguishing between congenital conditions and those which were the result of injury. The elastic tissue of the skin was not re-formed after an injury had been sustained sufficient to cause a scar.

Mr **W. G. Earengey** did not agree with those who asked for another definition of rape for legal purposes. The doctor could tell whether violence had been used in a given case, especially as most of the cases came before the doctor soon after the alleged attempts. And he did not think that judges were far behind the advances of science.

The **Chairman** thought that there was no great difficulty in deciding about penetration; usually there was a good deal of local evidence of violence. An important point was that these cases of attempted rape were surrounded by such a feeling of horror that

Dr. P. F WATKIN said he had found lotio calaminæ very useful, and for tropical ulcerations he recommended irrigation by dropping methods or by soaking the leg for hours in a bath. The chief features of treatment were cleanliness, rest, and the application of an antiseptic, such as perchloride with a little salt.

Dr STEBBING agreed that the problem was how to keep the part clean. The bath was not very comfortable, and he had found boric compresses better when once the skin was clean. All kinds of hyperæmic methods were useful—kaolin, glycerine pastes radiant heat, massage, and electricity. If the scar were soft and could be pinched up recurrence was unlikely.

Dr. A. P. BERTWISTLE said that traumatic ulcers resulted from bruises and abrasions which were so insignificant that they were neglected. The causes of chronicity in an ulcer were: (1) Poor blood-supply. The deep fascia, the duty of which was largely to carry and support blood-vessels, joined with the periosteum of the tibia over its subcutaneous border, so that there were few vessels in the area. (2) Such ulcers became fixed at an early stage to the bone which cut off the vascular supply to their base. If periostitis did not occur as the result of the blow, it would develop later. (3) The exposed position militated against rest. (4) The absence of fat in the subcutaneous fascia meant that there was no cushion to break the impact of a blow or make the part elastic. (5) The dependent position was not conducive to a good blood-supply. Abrasions, he said, should be allowed to dry, the resulting eschar being the best protective for them. In America they had tried electric drying as in shampooing. If dirt were ingrained hydrogen peroxide was beneficial for a day after which the wound should be allowed to dry. Lotio calaminæ worked like a charm in some cases. Rest in bed was essential if there were varicose veins. Iodoform disguised the smell of putrefaction, but iodine was bad and caused much pain. Boric ointment in a paraffin basis was useful at certain stages.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS

A MEETING of this Section was held on Feb. 4th, Dr LOUIS CASSIDY (in the absence of the President) in the chair, when Dr BETHEL SOLOMONS read a communication entitled

Rupture of the Uterus Treated by Plugging the Rent

The patient was aged 35 and had had three normal labours. During the second stage of labour her doctor had given her 1 c cm. of pituitrin and as there was no advance after an hour had applied forceps and delivered a stillborn child. Efforts to express the placenta and to remove it manually had failed.

On admission she was pulseless and in a condition of profound shock, just conscious. Routine treatment showed little reaction and the placenta was sought for. The cervix was closed, but on following the cord it was found that the uterus was separated from the fornix on the left side and that the placenta was among the intestines; it was removed. Intestines appeared at the vaginal vault and the rent was plugged with a large tampon of iodoform gauze. Two days later symptoms of intestinal obstruction appeared, and the gauze was removed. For 14 days she got on well, but there was always some distension without absolute rigidity. Symptoms of slight peritonitis then appeared and the abdomen was drained; two pints of foul sero-sanguinous fluid escaped and a drainage-tube was inserted.

Since then, said Dr. Solomons she has progressed well, but there was still some discharge from the wound, which it was hoped would clear up with ultra-violet rays. This patient would have died had laparotomy been done. she had lived after the treatment of plugging. Plugging was a valuable aid to obstetrical technique and could be carried out by the general practitioner. The rupture had occurred probably from the overdose of pituitrin in the second stage of labour. 1 c cm. was far too large a dose. If pituitrin was given at all, two or three minims should suffice, and it should only be given in selected cases.

The CHAIRMAN agreed that when a patient came to hospital in a condition of shock, as in this case, there was nothing to be gained by laparotomy. Most of these cases, if they did not die of shock, died from sepsis within ten days. He mentioned the statistics published by Döderlein from cases of rupture of the uterus at the clinic at Munich during the last 50 years, when there had been 50 cases. Seven of the cases had been untreated and had died. Ten had had laparotomy performed, and of these 60 per cent had recovered. The other cases had been treated in various ways. Eight of them had been treated in a way similar to that described by Dr Solomons and three had recovered. On the whole the average of recovery had been between 40 and 50 per cent. during the last 50 years. He thought that in this case the large amount of pituitrin which had been given was probably responsible for the condition. If cases were not too shocked he thought they were better treated by laparotomy; but a great deal depended on the method by which the shock had been brought about, and also on the time which has elapsed since the rupture had taken place and when the patient was seen.

Mr W. PEARSON said that it was very difficult in this case to decide what to do after the primary shock had been overcome. It was a question of either peritonitis or intestinal obstruction. It proved, however, to be an obstruction, and the patient had done fairly well for a fortnight. After that time the temperature had risen and the abdomen had become distended and soft; but it was plain that it was not an obstruction, as the bowels moved if purgative or enemata were given. There was a good deal of dullness in the right iliac fossa, extending across to the middle line, and the probability was that it was a case of mild peritonitis. The abdomen was opened, and peritonitis was found; there was a great deal of turbid fluid and also adhesions the whole way across to the abdominal wall.

Dr CANNON said that these cases were rare. He personally had only come across two. One was caused by the injudicious use of pituitrin, and the baby had died. The other was a case of spontaneous rupture from a previous scar. He did not think that there was any great danger of sepsis if the gauze was left on for 10 or 15 days. He thought that if the fœtus was completely in the peritoneal cavity it would be difficult to deliver the baby, unless the scar was extended; and it would add to the shock to deliver the baby per vaginam. In these cases he thought laparotomy should be done.

Prof DAVIDSON asked where the rupture was in this case; was it in the uterus or not? He had had three cases of rupture of the uterus, two following version and one following a breech. In the first case the rupture had been discovered when trying to extract the placenta; the rupture was in the fornix. The placenta was removed by traction of the cord and the hand was never inserted at all. He thought that this was a very good point in technique, as in this way it might be possible to avoid introducing sepsis into the abdominal wall. In all his cases the wound had healed. He asked if there was any possibility of the collection of fluid in the abdomen being urine, as he thought perhaps the bladder had been injured by the rupture, as sometimes the bladder was concerned in cases of ruptured uteri.

Dr SOLOMONS, in reply, said that he had met three cases of rupture of the uterus in the past three months—the one he had reported, which lived; one of quiet rupture which died; and another one which occurred on the previous day where there was a spouting uterine artery. In this last case hysterectomy had been necessary and the patient was still alive. Plugging was the best treatment when possible, but there were some cases in which laparotomy alone could be done. The practitioner must choose his case for justifiable without a bacteriological examination It was reported that the *Streptococcus scarlatinæ* persisted for some three to six weeks after the symptoms had subsided

SIR **FREDERICK ANDREWES** discussed the question whether there was such a disease as scarlet fever clinically—i e, whether it was a sharply defined entity, or whether it shaded off into other streptococcal manifestations, so that it was difficult to say what was scarlet fever and what was not He had seen, in 35 years, hundreds of cases of doubtful scarlet fever from the wards, the origin of the infection being undetermined The same sort of difficulty was encountered in regard to the bacteriological evidence Was it always the same kind of streptococcus which caused recognisable scarlet fever? Dr Griffith had declared that there were three different serological types of streptococci which could be obtained from the throats of scarlet fever patients, and the two sorts which were commonest in this country were not those which seemed to be commonest in the United States Might it not be that in scarlet fever there were several different races of streptococci which formed one common toxin? A lady who was working in his laboratory had last summer got what was, clinically, acute rheumatic fever She had been given some of Dr O'Brien's concentrated antiscarlatinal serum with strikingly beneficial results When, later, she had a relapse, another dose of it caused the temperature to come down to the normal in four hours and the pain to disappear from the joints

Dr **ALEXANDER JOE** agreed that in London, owing to the mildness of the infection, there was little opportunity for judging of the clinical value of this serum; in Edinburgh the disease was definitely more severe Until he came to London he had not realised what serum sickness was, he did not know whether this was due to the greater sensitiveness of the children in the south or to the type of serum supplied for London. He thought a reason why good results did not follow in septic cases was that the serum was generally used too late As to Sir Frederick Andrewes's remarks, Dr Joe had heard a laryngologist say that after mastoid operations his patients often got erysipelas, whereas after tonsillectomies a much commoner sequel was scarlet fever

Dr **C J MARTIN** asked whether there was experience of an epidemic spread of any other form of streptococcal infection, such as occurred in scarlet fever

Dr **J E MCCARTNEY** referred to the case of a hospital maid who had scarlet fever, and contracted erysipelas when she was partially recovered from the first infection, After that, when the temperature came down, she had pyæmia and a hæmolytic streptococcus was isolated from the blood Much more work was needed before laws could be laid down about the degree of infectivity of cases of scarlet fever. Much light might be gleaned by a close study of the organisms responsible for the failures

Dr **H J PARISH** described experiments on the titration of scarlet fever antitoxin in rabbits (vide THE LANCET, Jan 8th, p 71)

Dr **GOODALL** and Dr. **O'BRIEN** replied

POST-GRADUATE HOSTEL.

THE final meeting of the Hostel was held at the Imperial Hotel on Feb 24th, when Sir **D'ARCY POWER** opened a discussion on

Chronic Ulcers of the Tibia.

These he grouped into non-infective, infective, and malignant Of the non-infective, he said, the commonest were the traumatic and the varicose Less often seen, and nearly always in women, was the small rather punched-out ulcer which gave very great pain, probably because there was a nerve-ending in the centre These could be cured by blistering or painting with silver nitrate First among the infective was the tuberculous, for the syphilitic was by no means the commonest, as was often supposed He had seen enormous numbers of osteomyelitic ulcers in Ireland, but fewer in this country. The infection started in the bone, extended through the skin, and ended as a chronic ulcer, usually associated with sinuses Another and different type of ulcer was that associated with gangrene He had seen large numbers of carcinomatous ulcers in regions where cancer appeared to be endemic Malignant ulcers of the tibia were apt to go on for a very long time before killing the patient

Treatment

Dr **G. F STEBBING** spoke of his experience of ulcers in a Poor-law hospital where very large numbers were encountered For over 15 years his institution had kept a ward of 90 beds for nothing else The important points in treatment were cleanliness and early attention An injury might heal quickly, but the resulting scar often had not enough blood-supply to stand active life, every little knock started the trouble again and finally periostitis set in Such cases did best if the scar were excised and the area grafted on to the deep fascia Much more difficult to treat were ulcers arising on a leg with faulty circulation, as with varicose veins and phlegmasia One third of his cases had been in women with a history of "white" leg after parturition, and in such women he had seen ulcers extending from knee to ankle and all round the leg Amputation was the only treatment for most of them, but even ulcers of this class might heal after a time with the leg at rest in a raised position and with antiseptic dressings which were not changed too often The complication of conservative treatment was that stasis produced adhesions in the tendon sheaths, with the result that the ankle appeared ankylosed, though really the lameness was due to matting of the tendons Therefore it was not really worth wasting time healing up the ulcer if amputation could be performed Some of the cases had septic infection through the deep fascia, and pus poured from the ulcer. The varicose ulcer was often associated with only a very slight degree of varicosity, but the circulation was always poor The ulceration seemed to depend largely on the recurrent phlebitis that affected the varicose veins It healed quickly and the leg kept well if the patient could be persuaded to sleep and spend a part of each day with her foot raised The pain was ischæmic in nature and was greatly relieved by a wedge under the mattress, 9 inches high at the broad end Hoskins made a special bed for such cases Dr Stebbings thought that parathyroid was not of much use An elastic stocking was better than bandages if the patient could afford to have a really well-fitting one, renewed about twice a year If there were varicose veins about the knee the stocking must be in two pieces so that bending the knee did not produce anæmia Unfortunately patients had to earn their living, the leg got knocked, and the ulceration returned

The Poor-law officer, Dr Stebbing continued, saw very little tuberculous ulceration, and syphilitic ulcers, like all tertiary syphilitic phenomena, were becoming rarer and rarer He had seen many of the so-called gangrenous ulcers, but they were not gangrenous in the ordinary sense of the term The condition began as a little spot which rapidly spread over the leg until the skin sloughed and left an ulcer This healed well and rapidly if treated with antiseptics, but if it were treated as an indolent ulcer for a long time and got a hard edge it would do badly, and matting of the tendons would probably occur Osteomyelitic ulcers were becoming more uncommon as treatment improved; nowadays they were more often seen over the femur than over the tibia One type of malignant ulcer began as a papule and grew without previous ulceration, starting apparently as a true carcinoma of the skin. a commoner form began on the site of a varicose ulcer and was seen also on the foot, even on the great toe, at the site of some chronic sepsis such as a bunion

Reviews and Notices of Books.

ARTIFICIAL LIGHT TREATMENT OF CHILDREN

By KATHERINE M L. GAMGEE, M R C S , L R C P., D P H London H K Lewis and Co , Ltd 1927 Pp. 172 10*s* 6*d*

THIS book embodies the results of the author's experience in a children's light clinic in an industrial town and contains much information which will be of practical assistance to all who wish to undertake light treatment for children A summary is given of the essentials of the rationale and technique of artificial heliotherapy and of the routine administration of the clinic The advantages and disadvantages of the carbon arc, mercury-vapour bath, and tungsten arc are clearly indicated , the author considers that, when the apparatus must be limited the air-cooled mercury-vapour bath is the most generally useful lamp for the treatment of children The part of the book devoted to clinical results is largely concerned with the treatment of rickets and spasmophilia The results obtained were undoubtedly good, as is demonstrated by the photographs and radiograms shown The efficacy of artificial heliotherapy in cases of this type will hardly be called in question ; it is, perhaps, a defect of the book that other types in whom the indication for radiation is less obvious are not discussed more critically In the classification of cases suitable for treatment "nervous children" are included, but the book yields no real evidence that neuroses of a non-spasmophilic nature are susceptible to radiation Still more questionable is the inclusion of the "mentally dull and backward child and also the child that gives signs of being mentally abnormal or mentally deficient" No further reference is made to cases of this type, and we suggest that claims should not be made unless supported by definite evidence, or disappointment may be caused An interesting feature of the course of many rickety patients was the progressive increase in hæmoglobin percentage Due prominence is given to the dangers of radiation in children with active tubercle

This book is clearly written, adequately illustrated, and of convenient size, and should well fulfil the purpose for which it was written

X RAY APPARATUS, ITS ARRANGEMENT AND USE

By P K BOWES, M.A , B Sc Examination for M S R (Dist), Hon Radiographer to the Kent and Canterbury Hospital, Canterbury London. H K. Lewis and Co , Ltd 1926 Pp 196 7*s* 6*d*

THOUGH this book is primarily written for those taking the various examinations for radiographers, it should prove useful to doctors who want to get a general idea of the way in which the component parts of an X ray apparatus work, and how it is that they sometimes do not work He will find here not only this information but also to what general uses the X rays, once produced, may be put Other chapters are devoted to a description of the means employed to control and measure the output of X rays from the bulb

The chapter on the nature of X rays is less satisfactory than the rest In speaking of the electron, the author says, "the charge on each particle also is invariable and is that carried by the hydrogen ion in liquid electrolysis," and, in talking about corpuscular rays, the reader is told, "the corpuscular rays have been found to be negatively charged particles called corpuscles which are given off in large quantities at very great speed" From these two statements, one would hardly guess at the identity of electron and corpuscle Some of the clear line drawings are spoilt by the attempt of the author to draw circles with some instrument other than a compass But on the whole defects are few and of minor importance in a reasonably priced volume which covers the interests of an increasing number of people.

THE TUBERCULOUS PATIENT

Handbuch der Tuberkulose—Fursorge By Dr KARL HEINZ BLUMEL (Halle) and others Munich . J F Lehmanns 1926 Vol I, pp 457 M 249. Vol II , pp 533 M 270.

THIS work is "a comprehensive text-book on the care and control of the tuberculous patient" Each section is allotted to an expert

The first volume is divided into two portions, the former dealing with the social and preventive medicine aspects of the subject, the latter being pathological and clinical The hiatus between the two parts is distinct and if a second edition is called for they might with advantage be issued as separate volumes The book opens with a historical survey of the subjects and then deals, in succession, with German legislation, statistics, the achievements of the antituberculosis campaign, and the regulation, management, and diagnosis of cases in the tuberculosis dispensaries Early pioneer work and the later and more elaborate forms of administrations are described The general editor, Dr Blümel, is justifiably proud of the German pioneers who blazed the trail in the exploration of tuberculosis—Brehmer, Koch, Rontgen, and Flugge A long section of more than 80 pages is devoted to the statutory provisions which Germany has enacted since 1884 for dealing with invalidity, infant and juvenile welfare work, industrial hygiene, and housing in relation to tuberculosis. Especially important is a section dealing with the recent legislation of 1924 with regard to social insurance and concluding with a critical survey of the aim of social legislation in relation to tuberculosis A short essay on notification in Germany and other countries is also included The death-rates from tuberculosis in the different German states are given up to and including the year 1924 As might be expected, these figures show very high peaks for the war years—culminating in a record in 1919, and slowly returning to pre-war figures thereafter The work of the antituberculosis campaign is shown in a specimen financial budget of the German Central Committee for 1925–26 and in various specimen forms for the compiling of statistics of cases treated These forms are similar to those used in dispensaries in this country Case sheets, the arrangement and organisation of the dispensaries, the provision and management of X ray plants in dispensaries, and other questions which exercise the minds of tuberculosis officers all receive careful consideration Little need be said with regard to the clinical portion of the volume, for books on this subject are now legion and it is becoming more and more difficult to set old facts in a new light Suffice it to say that the salient facts are clearly and concisely set forth with due emphasis on the right points For the English reader the preventive medicine sections are the most interesting as a demonstration of the thorough way in which the German antituberculosis campaign is carried out Numerous graphs, diagrams, illustrations, and useful bibliographies are included A spot map or geographical diagram illustrating the organisation of the preventive work in town and country in Germany would have been useful to the foreign reader.

The second volume contains sections on the prevention of tuberculosis, on treatment from the point of view of the social worker, on dispensary statistics, on education, and on the antituberculosis campaign in other countries The discussion on prevention is based on the modern conception of a primary infection in childhood It is a careful analysis of the "contact" question, from which the writer draws the conclusion that chronic disease in childhood is generally an intrafamiliar and acute disease an extrafamiliar infection The chapter on housing treatment In the one he had described the uterus was completely separated from the vaginal vault, and he believed that the gauze had temporarily obstructed the bowel—a complication he had never before encountered At the time of the second operation ileus from the peritonitic fluid was the trouble

Dr **Solomons** also read notes on Epistaxis as a Symptom of Toxæmia of Pregnancy

Prof **Davidson** showed a case of Salpingo-vesical Fistula

EDINBURGH OBSTETRICAL SOCIETY.

At a meeting of this Society held on Feb 9th Prof R. W **Johnstone**, the President, took the chair, and Dr **Farquhar Murray** (Newcastle) read a paper on

Rupture and Inversion of the Uterus

He objected to the terms complete and incomplete rupture, suggesting that they should be replaced by intra- and extra-peritoneal rupture The chance of rupture of the scar of an old Cæsarean section was, he thought, greatly exaggerated, but it should be kept in mind, and in such a case the uterus should be spared all possible stress at subsequent confinements During the last five years he had performed or had records of 50 repeat sections, and none had shown evidence of imminent rupture Though in some of them the area of scar tissue was thinner than the surrounding muscle, it was in all cases tough and firm If a scar should rupture or become thinned out at a future labour, the wound edges should be excised before resuture so that healthy muscle would be reached on both sides of the wound The worst traumatic ruptures seemed to occur after versions performed when the uterus was tightly contracted and Bandl's ring greatly in evidence To avoid such a risk, perforation of the head, followed by compression with the hand, was advisable, a careful version then being performed, with this treatment the lower uterine segment would not be subjected to so great a strain After a difficult version manual removal of the placenta was also desirable, partly, diminish the risk of post-partum hæmorrhage, but mainly in order to explore the uterus thoroughly so that any rent in its wall might be detected Dr Murray was surprised at the degree of trauma to the cervix caused by spontaneous deliveries, even when the fœtus was as premature as at the seventh month Some of these lacerations spread up to the body of the uterus and cause repeated abortions and premature labours Curettage did not help the furtherance of pregnancy and cervical repair might have to be done As the extent of the tear could not be definitely determined from below and dissection from the vagina was apt to imperil the ureter and might tear into the uterine vessels, Dr Murray recommended an abdominal operation for the efficient suture of the tear

Describing a number of cases of inversion of the uterus, Dr Murray said that he had difficulty in accepting the usual explanations of its causation, as he had noted how difficult it was to cause inversion of the uterus directly with the hands in a Cæsarean section and also how often a vigorous Credé was practised without any untoward result He thought that the arrangement of the uterine muscle played a definite part in the process, as in several Cæsarean sections he had noted that the thick part of the uterus was the centre whereas the upper part of the uterus was nearly as thin as the lower uterine segment It would be, therefore, quite easy for the thin portion to be pushed, pulled, or even spontaneously invaginated and gripped by the thicker zone of muscle

Dr **Ralph Lodge** then read a communication on

Hydatidiform Mole,

in which he reviewed 37 cases treated in the Royal Infirmary or Royal Maternity Hospital since 1922 About 70 per cent of the cases, he said, occurred in the third decade of life and only 8 per cent after the age of 40 years, 30 per cent occurred in primi gravidæ The clinical features noted were mostly those usually described, though a "brownish discharge" was often complained of Severe vomiting was a common symptom and it was interesting to note that 50 per cent of the patients had albuminuria The Wassermann reaction was negative in all cases Nineteen cases, he said, had been followed up and only one had developed chorion epithelioma He had discovered by investigating the records of the various pathological laboratories in the city that in Edinburgh and the surrounding districts hydatidiform mole was extremely rare, only six cases having been reported upon in nearly ten years He thought that immediate curettage after expulsion of a mole should not be done, as his statistics of treatment showed that this operation was frequently followed by a morbid convalescence, whereas if any symptoms should warrant curettage and this were done at a later date the morbidity was not nearly so great He found that the complications which were most common after expulsion were first and foremost, sepsis (46 per cent having a morbid convalescence), and then hæmorrhage (8 per cent. having severe hæmorrhage), and then development of chorion epithelioma (1 case) Perforation of the uterus did not occur in the series Vaginal hysterotomy had proved satisfactory and abdominal hysterotomy was also useful sometimes, especially when the uterus was as large as with a full-time pregnancy

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH

On Feb 22nd Dr A Rowand read a paper on Oxaluria, with special reference to its occurrence in children He pointed out that the term oxaluria was of very vague significance and was applied to a variety of conditions As a condition with clinical symptoms it was first described about the middle of last century A chronological survey of the opinions expressed in clinical text books from the days of Golding Bird showed that the tendency had been to lay less and less stress on any possible causal connexion between the oxalates and the general symptoms, and to regard them as having a common origin in some disorder of metabolism The possible sources of oxalates were various, and therefore it could not be said that the presence of oxalate crystals in the urine indicated one definite error of metabolism Moreover, there were individual idiosyncrasies Of two individuals on the same diet one might show a large deposit of oxalates in the urine, while in the urine of the other no oxalates could be found This might happen even when substances rich in oxalic acid, such as rhubarb, were being taken Again, the occurrence of hæmaturia was apt to be regarded lightly if many oxalate crystals were present in the urine, but probably in a healthy urinary tract irritation by the crystals was unlikely to cause such a serious symptom All writers laid stress on the danger of the formation of calculi but this was not solely dependent on the amount of calculous material in the urine Benjamin Moore had shown that in the core of a calculus some colloidal substance was present in association with the calcium oxalate It was not suggested that the occurrence of oxalate crystals in the urine of children was of greater significance than in adults But the urine of a large number of children who came to the institute for periodic observation provided a valuable field for study Specimens were examined at every visit, and as they were voided at the institute it would be possible to determine the extent to which the presence of oxalate crystals in fresh urine was associated with symptoms of impaired health The investigation had been in progress for about a year In only 14 per cent of the specimens had oxalate crystals been found though 30 per cent to 40 per cent was the figure commonly given This lower percentage might be due to the fact that all the specimens were freshly voided, and that a large proportion of the children were in good health In about 20 per cent of cases traces of protein had been associated with the oxalates Red blood cells were only found in a very small proportion of the specimens There was some ground for believing that not only the number but the nature of the crystals might be of special significance Refractile particles and minute octohedra appeared to be especially associated with symptoms of disordered metabolism and impaired health But the investigation had not proceeded far enough to make it justifiable to pronounce any definite opinion on this matter

THE LANCET.

LONDON: SATURDAY, MARCH 5, 1927

OGRESS IN RESEARCH ON FOOT-AND-MOUTH DISEASE

The Foot-and-Mouth Disease Research Committee, which the present Chairman is Dr Charles J rtin, has just issued its Second Progress Report [1] Committee was appointed by the Ministry of iculture in 1924 and during the past year has ered serious loss by the deaths of Sir William shman, the chairman, and Sir Stewart Stockman report contains information of great interest ring especially on the methods by which the sease is spread and on attempts to produce artificial munity There are three appendices the first the late Sir Stewart Stockman and Mr F C nett, gives details of the work carried out at the oratories of the Ministry at New Haw and at Pirbright Experimental Station, the second is Dr S P Bedson, Mrs Y M Burbury, and H B Maitland from the Lister Institute, and last contains a bibliography of foot-and-mouth ase since the beginning of 1924 The number experiments and conclusions recorded, and the f results in the directions indicated, follow

ost previous observers had emphasised the lity of the virus to resist drying Indeed, in Loffler laid down that only under moist tions could it survive in the outside world, ugh it is true that Roux, Vallée, Carré, Nocard recorded experiments showing that l fluid rapidly dried in vacuo may sometimes e for as many as 18 days Experiments recorded present report show that when dried on a glass virus in diluted filtrate of vesical fluid will e over pure sulphuric acid for a year, and that it is placed on favourable material, and dried ordinary atmospheric conditions in the labora he survival may continue for several weeks ol or filter paper the virus did not remain longer than a week, but when allowed to dry , bran, or flour, without special precautions avoidance of light, the virus was found infective for guinea-pigs after 12, 20, and s respectively Such surprising viability erials used as fodder cannot be without l significance, and it is interesting to note utwein [2] has also recently published evidence resistance of the virus to drying for long especially when contained in pieces of epithe- The danger from these sources has been home by the discovery that the skin on the the bone marrow of pigs killed during the stage may not only contain active virus able by experiment with guinea-pigs, but t healthy pigs, especially if the bones are p and fed to these animals These facts, scovery that carcasses of pigs showing lesions sease had been imported during the past his country and could be made to reproduce e experimentally, have materially aided the nt of preventive measures Knowledge urther advanced by a series of experiments on the survival of virus in carcasses under varying conditions, including burial and preservation in brine

The other investigations in the report and which may have far-reaching results are those on the protection of guinea-pigs by a non-infective vaccine made with dilute vesical fluid treated with formalin The protection against inoculation with the virus afforded to guinea-pigs by a single dose of this vaccine is very striking and a great many observations on the dosage and degree of resulting immunity are recorded So far the experiments have been made almost entirely with these animals, but there is evidence that an intramuscular dose of formalised vaccine may protect a calf against the same strain of virus also given intramuscularly The protection in this way of highly susceptible animals such as cattle and pigs against natural infection has not yet been achieved, though Vallée, Carré, and Rinjard last year reported a success with a formalised vaccine followed by a living dose of virus The subject of immunity to foot-and-mouth disease is complicated by the existence of the two distinct types, described by Vallée, which do not give protection, the one against the other Confirmation of this observation is also to be found in the report It may be noted that Waldmann and Trautwein have recently described at least three separate types of the disease in Germany where the existence of more than one type was not at first accepted A large amount of work has also been done on the immunity of experimental animals, the testing of protective serum, and its mode of action Experiments on the infection of rabbits, cats, dogs, and birds are also recorded, all these animals can be infected experimentally but only rarely, if ever, prove infective for others Though these are of considerable interest and importance from the theoretical point of view, they do not appear to have much immediate practical application Further attempts to culture the virus on artificial media have proved unavailing On the whole, however, the Second Progress Report, besides providing much new and interesting information about this typical example of the filtrable viruses and the disease which it produces, encourages the hope that the Committee's labours will lead to further results of great importance

QUALIFYING EXAMINATIONS FOR NURSES

The qualities needed for looking after the sick are largely temperamental, and of numerous women it has been said that they were born nurses This means that nursing must always be a vocation—that it is not a mere trade in which the most skilful are necessarily the most successful, and the distinction is especially important to remember now that State examinations have to be passed before a nurse can enter her profession It is not enough to be born, she must be registered as well, and though this is admittedly desirable it introduces a principle which may easily be carried too far A qualifying examination is always dangerous, because it lays emphasis on certain attributes in the candidate, and it is necessary to be careful that these attributes shall be those on which efficiency depends There are special reasons, moreover, for care in choosing examinational standards for nurses The first is that since registration was devised as a means of raising the status of the nursing profession, there is a risk of the standards being set too high by people who have in mind an ideal which is for the time being unattainable, any new mechanism of progress is liable at first to over-use The second reason is that at the present time there is a shortage

---

rogress Report Foot-and Mouth Disease Research H M Stationery Office 3s net

r wissenschaftliche und praktische Tierheilkunde, 3 shows that Germany is faced with the same economic problems as ourselves, problems which are indeed world wide at the present time The chapter on disinfection also stresses the same point—viz, the high cost of disinfection when thoroughly carried out. One district is quoted in which it was possible to effect household disinfection after the death of a tuberculous patient in only 57 7 per cent of instances Amongst other valuable information given in this chapter is an inquiry into the relative cost and sterilising value of antiseptics Forest schools, sanatoriums (with plans for construction), and the colony system all receive attention Much emphasis is laid on education propaganda and special chapters are devoted to the patient in relation to the family, the nursing sister, the medical student, the practitioner, the school, and the press

THE ABDOMEN.

Anatomie Medico-Chirurgicale de l'Abdomen: III, la Region Lombaire et le Petit Bassin Par RAYMOND GREGOIRE. Paris · J. B Baillière et Fils 1926 Pp 304 Fr.30

THE third, and last, volume of Prof. Gregoire's original work on the abdomen is disappointing; this feeling is really due, in large part, to the vivid impression left on us by the last volume of the series Nevertheless the book is a disappointment in other ways also We refer especially to the confused impression which it gives, possibly owing to the arrangement or order in which the separate parts are considered That the matter itself is good goes without saying, in view of the reputation of the author, but the book does not give us the same clear mental pictures of the parts as were suggested by the admirable descriptions in the earlier volumes This is especially noticeable in the section dealing with the pelvic organs, where the accounts seem meagre and disconnected However, the completed work, as a whole, is one of definite medico-surgical value

A FIRST COURSE IN HYGIENE

Seventh edition By ROBERT A LYSTER, M D, B Sc Lond, D P H Revised and enlarged by Colonel R J BLACKHAM, C B, D S O, M D, D P H. Lond London · W. B. Clive. 1926 Pp. 335 4s

THIS little book covers a wide field, ranging in 22 chapters from the anatomical structure and functions of the body and its various systems through the usual gamut of information regarding ventilation, foodstuffs, personal hygiene, soils and sites, water-supplies, housing, cleansing, and refuse disposal, to elementary first-aid, communicable diseases, and disinfection The excellent policy is adopted of introducing each practical aspect of hygiene with an elementary exposition of the physiological and anatomical problems involved There are numerous illustrations and each chapter concludes with instructions for the carrying out of simple illustrative experiments Necessarily it is potted knowledge of the kind which external examinations are encouraging examinees to absorb

The book presents the unevenness associated with attempts to bring an old work up to date While there is quite adequate consideration of the accessory food factors, the almost equally important question of the balance of amino-acids in proteins is overlooked, and although the influence of irradiation on cholesterol is casually mentioned, the physiological influence of the deprivation of light, and more especially of ultra-violet rays, on the human organism is entirely neglected Some inkling of present day ideas about ventilation is contained in the chapter on air and respiration, but it is counteracted under "ventilation" by the emphasis laid on "organic impurities" Measles is described without Koplik's spots and we are told that "all contacts [with enteric fever] . . . should be quarantined for a month". Disinfection is dealt with in much detail, but no mention is made of modern views as to the relative importance of disinfection among the munitions of hygiene The task of writing or revising a book of this kind is an unenviable one and we do not wish to suggest that this one is not more than worth the exceedingly low price at which it is sold, but the announcement that it has been "brought thoroughly up to date" can hardly be substantiated The danger is that it will be found difficult, as our knowledge advances, to re-educate the increasing body of persons who are acquiring from small manuals dogmatic information which is even now questioned in enlightened circles

THE NORMAL CHILD.

By B SACHS, M D. New York Paul B Hoeber 1926 Pp 111. $1 50.

THIS little book sets out the substance, presented in a form intended for parents and teachers, of the chapter on the Normal Child in Sachs and Hausman's recent work on Nervous and Mental Disorders from Birth through Adolescence The author's attitude towards many problems of the development of the child is decidedly conservative and may even be considered reactionary by the adherents of some modern cults His advice to parents throughout the book is to be guided by common sense and not by psychological theories While he holds no brief for the current methods of intelligence-testing and the inferences drawn from them, or for the behaviourist point of view, it is the Freudian interpretation of psychological mechanisms, particularly as it involves the relation of the child to family and environment, that is the principal object of his attack In a chapter entitled "The Evils of Psycho-Analysis" the whole structure of Freudian psychology is represented to the reader as unscientific in theory and mischievous in its application to the upbringing of the child

On the positive side the book contains much valuable advice, which may bring assistance and relief to parents who have received from contemporary litera ture the impression that discipline and parenta influence have no place in modern child-training

SOLUBLE AND INSOLUBLE BISMUTH SALTS IN SYPHILI

Solubles ou Insolubles, le Benzo-Bismuth
Syphilithérapie Par le Dr HENRI DROUI
ex Chef de Laboratoire a l'Hôpital Broca, Laure
de la Faculté. Paris: Editions Paul-Marti
Pp 96 Fr 6

Dr Drouin, in this monograph, makes out a g
case for the administration of soluble salts of ben
bismuth in syphilis, and is, indeed, most spirited
their defence After experiments on rabbits
guinea-pigs, and from observation on patients s
1919, he is firm in the belief that administratio
trioxybismutho-benzoate of soda, in sulphure
aqueous solution, administered by the subcutan
or intramuscular route, is better tolerated
generally and at the site of injection than the inso
salts He also considers the drug to be less t
better eliminated, and more easily handled O
insoluble salts he seems to favour only the qu
iodo-bismuthate preparations Syphilologists i
country have not so far come to this conc
but have found the tartro-bismuthates an
hydroxides of bismuth, as well as quinin
bismuth preparations effective both in c
syphilitic lesions and in changing positive Wass
reactions to negative, with relatively little tox

WEST KENT MEDICO-CHIRURGICAL SOCI
meeting will be held at the Miller General
Greenwich, on Friday, March 11th, at 8 45 P.M.
Birley will give an address on Some Problem
Treatment of Neurosyphilis.

from the point of view of the public, the medical profession, and the nurses themselves, is for a more copious supply of women who wish to take up nursing Good material is almost certainly available, and it would be a pity if the enthusiasm of suitable people were inhibited by too ambitious a scheme of education Excess of book-work means a heavy strain on the minds and spirits of probationers Any loss of good recruits from this cause seems especially regrettable when it is realised that theoretical knowledge is at best an unsatisfactory criterion for the selection of nurses.

◆

HEALTH IN INDUSTRY

THE Industrial Health Education Society is an organisation for the spread among the British industrial population of fundamental lessons for the maintenance of health It had its origin in a Scottish body entitled the Industrial Health Education Council, and its first annual meeting, held last week, therefore properly took place in Edinburgh Sir WILLIAM HALDANE, who presided at the meeting, laid stress among other things upon the enormous pecuniary loss that is represented by the presence among workers of widespread preventable sickness, largely of occupational nature, and was following in the footsteps of many prominent speakers upon similar occasions when he declared that education would be the surest means of enabling the workers to defend themselves from the evils of ill-health as they prevailed in their particular occupations There can be no two opinions on the matter Parliamentary regulations and statutory by laws have a good outcome, still larger effects accompany the dissemination of authoritative information from the Ministry of Health, such as now reaches the public through the newspapers, but direct appeal to the section of the populations especially concerned by means of lectures, demonstrations, and propaganda generally produces prompter results, particularly if the appeal can wear the shape of a message that everyone should help himself and his comrades in accordance with the counsel laid down Organisations of the workers and individual workers are quick to grasp the real positions when they are placed clearly before them in this manner, and will assist in any public movement for the abatement of the demonstrable ills

At the meeting of the Society referred to, Sir WILLIAM HALDANE, in moving the adoption of the annual report and financial statement, dwelt upon the unfortunate habit prevalent among all sections of society, industrial and other, of waiting before calling in the doctor until the peccant condition was so far established that remedy had become proportionately difficult and sometimes impossible This, again, is a statement which has been made in public often before, and which cannot be too often repeated because it indicates the difficulties which lie before the medical profession in carrying out its ideals in the matter of prevention The medical profession is constantly told that much of the mortality from malignant disease is due to the absence of early treatment, but, as Mr STANLEY WYARD points out in a letter in another column, early application for treatment must take place before the medical man can make the early diagnosis, the need for which is perpetually revealed Such early application will become much more frequent as the public learns, through a wise spread of the right knowledge, what are the things that matter, what are the just causes for apprehension, and what are the conditions commonly associated with the appearance and the spread of sickness That the public is anxious for such information is well proved by its attitude during the recent pandemic of influenza, when the desire for trustworthy guidance on the personal aspects of prevention was clearly manifested, and manifested in hard circumstances, for neither the Ministry of Health nor anyone else was able to give authoritative replies to categorical questions, owing to the limitations of our knowledge These limitations had an unfortunate sequel in that the inability on the part of responsible persons to prescribe a panacea gave an opening to the irresponsible, many of whom rushed into the breach and made pronouncements, advocating measures which were sometimes mutually contradictory and sometimes those which the Ministry of Health had put forward tentatively and which were now pressed upon the public with assurance and without discretion But the position is a difficult one In the face of an epidemic the people ask for a sign and are dissatisfied when they are told that no sign can be given, and that the only exorcism is a way of living which is often equally applicable to non-epidemic times It is true that such occasions may be seized upon for driving home sound doctrines upon domestic hygiene, and for the expression of sensible reflections upon proper ventilation, the use of exercise, the rôle of clothing, and the need of dietetic precautions, experience, however, has shown that these lessons are soon forgotten when the emergency is passed, and also, alas, that those who observe the lessons are not by any means exempt from the epidemic Here, of course, is where the dogmatic general advice fails particularly badly in the matter of dietaries, for not only is the gospel truth of one adviser at variance with the rational conclusion of another adviser, but patients conform only in a rough manner to a common pattern, and supply therefore a considerable percentage of persons who fail to react as their fellows may do

There should be a valuable future for the Industrial Health Education Society, the dissemination of public messages on health topics is a matter which bristles with practical difficulties, and all intelligent attempts that are made to cope with these difficulties are therefore welcome The purpose of preventive medicine is not only the reduction of disease or the postponement of the event of death, but the strengthening of the health and the raising of the standard of physical capacity of the normal person The private practitioner has opportunities for keeping the normal individual on the track of health, while the public medical services are largely concerned with the already damaged There is definitely a need for some form of systematic education of the public in matters pertaining to health This is so far recognised that the organisation of propaganda has almost become a special branch of public health administration Health departments have at their disposal, mostly through voluntary organisations, panels of paid lecturers, travelling exhibitions, lantern slides and synopses of lectures, films and posters, handbills and pamphlets Mass attacks are frequently organised in the form, for instance, of Health Weeks But far as we have gone in this direction, we are still a long way behind America where the "selling" of health, with the aid of innumerable artifices for catching the public eye and ear, has received a great deal of attention Dr Almus Pickerbaugh is a grotesque, but he illustrates a movement which is quite real in America Are we right in our view that the British public are less receptive? And is our more

[illegible]
G. S. Medical College

of candidates for the nursing profession and it would be sad if either the qualifying examinations, the study required for them, or the conditions of training entailed, were regarded as a bar to the service by girls who were otherwise suitable The third reason, which has been indicated already, is that knowledge is on the whole less important in nursing than are temperament, health, and the kind of practical ability which either is inborn or comes with experience Training and book-learning are useful supplements, but the public should not be encouraged to think that an aptitude for acquiring theoretical knowledge is an essential part of the nurse's equipment

These reflections arise from perusal of the examination papers recently set by the General Nursing Council for England and Wales In the Preliminary Examination held on Feb 1st the candidates were probationers of one year's standing and in their first paper they were invited to answer three of the following questions, including one from each section

A Anatomy —(1) Give a short anatomical description of the knee-joint (2) What parts of the body receive their blood-supply through the innominate artery? (3) Describe briefly the cavity of the pharynx, and the various openings which communicate with it

B Physiology —(1) Describe the various kinds of blood corpuscles What do you know of their functions? (2) How does the body obtain its store of glycogen, and what are its uses? (3) What are the functions of the lymphatic vessels?

Most of these questions might be asked in examinations for the highest medical and surgical degrees, and it must be supposed that the Council's examiners are content to receive very simple and dogmatic answers The candidates, however, have little assurance of this, and anxiety will not be diminished by turning to the "Answers by a Sister-Tutor," published in the *Nursing Times* Dealing on Feb 19th with the examination paper we have quoted, the sister-tutor answers the third of the anatomical questions and begins as follows —

> "The pharynx is a muscular tube suspended from the base of the skull and lying directly in front of the cervical vertebræ Its upper portion, which lies behind the posterior nares, is called the naso-pharynx and the lower portion behind the mouth and tongue is the oro-pharynx. It is lined throughout with mucous membrane, which is continuous with that of the nares and mouth above and that of the larynx and œsophagus below The muscles of the pharynx are largely arranged in circular and longitudinal fibres, which contract alternately, forming a wave-like movement during swallowing At intervals throughout the pharynx are patches of lymphoid tissue, which are a great safeguard against the entry of disease germs, the chief being at the base of the naso-pharynx"

She continues in this strain for another 320 words, ending with the statement that "the cricoid cartilage below is the *only* complete ring of cartilage in the trachea and is narrow in front and broad behind" Her answer is a praiseworthy summary of the facts, but it does not suggest that candidates are intended to reply to the questions only so far as they bear on the practice of nursing, as might otherwise be presumed Nor can this limited requirement be inferred from some of the papers set in the Final Examination for the General Register, which was held on Feb 2nd The first paper begins thus —

Medicine —(1) Give the symptoms and signs of rheumatic fever, pointing out the differences as found in children and adults (2) What is meant by "pleurisy"? What are the different forms? Give the symptoms of each (3) What are the chief causes of irregular enlargements of the breast? What advice would you give to a patient with such condition if she applied to you?

The candidates had to answer at least one of these questions, whilst among the alternatives in the second section was, "What dietetic and local measures might be recommended for an adult patient with severe eczema?" This question is far from being beyond criticism, but even more controversial are two others in which the nurse was asked to indicate the chief characteristics of the various kinds of ulceration of the cervix (stating what methods of treatment might be employed in each), and was expected to give some account of "the principles underlying the use of antitoxins and vaccines in infectious disease"

It may be that in practice the Council does not reject candidates for their ignorance on the questions we have quoted, it may be that its bark is worse than its bite At the moment, however, the bark is likely to have unfortunate results The recent examination papers deal with too many subjects of which knowledge is not essential to every nurse The fact that the questions have alternatives will not prevent the conscientious student from trying to cover the whole ground surveyed, and the scope of the examinations makes it necessary for the schools of nursing to cram their pupils with facts which cannot be digested Much of the theoretical teaching nowadays given does not arise naturally from work in the wards, but rather out of the demands of the examining body Everyone will agree that an elementary knowledge of physiology and anatomy is all to the good, but a nurse must seldom find it necessary to remember morphological details, nor is it desirable that probationers should be taught to think in this peculiar way And here, indeed, is the crux of the matter There is no time to teach a nurse to think like a medical man, even if there were inclination, and if she is taught a great number of facts, without being instructed in the use of them, it is quite possible that she will end by getting a dangerously false impression of her powers In diagnosis, with which some of the questions incidentally deal, there is nothing more risky than the half knowledge which comes from reading elementary handbooks, and the nurse who relates her patient's every symptom to the medical adviser is a far safer assistant than she who fancies herself an amateur doctor Frequent reference to a medical man is, of course, a counsel of perfection, for many nurses carry on their work in places where help is not available for weeks at a time In such situations they have to use their discretion, which is often admirable, but these posts should only be entrusted to experienced women or those with special training Admission to the State Register is surely not meant to imply that the newly qualified nurse is fitted to assume diagnostic responsibility It ought merely to show that a candidate has the knowledge essential for efficient nursing—that she can keep a patient clean and comfortable, dress his wounds, prepare his food, administer the remedies prescribed, observe and report on his condition, and cope with emergencies which are likely to arise These are no easy tasks, but they do not require knowledge of the innominate artery, the kinds of blood corpuscle, the metabolism of glycogen, or the functions of lymphatic vessels Such information will doubtless increase a student's interest in the human body, and within limits it is valuable, but it is seldom, if ever, of immediate practical importance in nursing, it is an extra and should be regarded as such To know about the varieties of ulceration of the cervix and the dietetic treatment of eczema is only necessary for those whose work is done under special conditions of isolation or responsibility The present examination seems to demand knowledge which it is hard to gain without either long experience or a special training which cannot be given to every probationer The result is a tendency towards widespread cramming The immediate need, alike destruction of the upper incisors in infants and attributed it to the use of a dummy dipped in some fermentable solution. In Mr Pitt's series a dummy dipped in carbohydrate was used in 43 children out of 74 The teeth extracted were kept and microscopical sections were made from two or three of each batch The enamel was usually so fragmentary that it was impossible to determine its structure, so attention was chiefly paid to the structure of the dentine The teeth were divided into three groups. (1) those which were well formed, (2) those which showed slight imperfections, but not enough to warrant the assumption that the defects implied a pathological cause, and (3) those which showed marked defects of structure and could be fairly termed hypoplastic The teeth of 40 children were examined microscopically, and in 20 of them the teeth fell into the first group, in 10 into the second, and in 10 into the third In this last group the defects consisted of rows of interglobular spaces in the dentine, to an extent which suggested that the defective structure was due to some interference with the process of calcification and that it must have lowered the resistance of the teeth to dental caries It is rather remarkable that visible defects of the enamel only occurred in 5 out of the 70 children examined, and that there were only three cases of visible hypoplasia in the series of teeth examined by microscope Only one of these, a case of fragilitas ossium, was placed in group 3

Mr Pitts summarises as follows In 58 per cent of the children there was a use of a dummy dipped in fermentable carbohydrate Both the carbohydrate and the way it was used, chiefly at night, provided conditions favourable to rapid and early caries In addition to this habit there was a history in some cases of the use of a biscuit or some similar starchy food being given at night Thus in rather more than half the children the caries could be accounted for by a dietetic factor But in a considerable percentage the dietetic history seemed insufficient to account for the caries, and the microscopic evidence which showed defective structure in 25 per cent of the children, suggests that this imperfect calcification may explain its onset As to whether the imperfect structure was due to lack of vitamins as suggested by Mrs Mellanby, no reliable data were obtainable, though the histories seldom revealed a definite lack of vitamins in the diet The harmful effect of the dummy comforter has long been recognised by infant welfare workers and the investigations of Mr Pitts should strengthen the prejudice against it.

THE NATURAL DURATION OF CANCER

A paper[1] on untreated cancer of the breast, by E M Daland of Boston, provides interesting confirmation from America of the findings published by Major Greenwood[2] for this country Daland deals with 100 and Greenwood with 651 patients All these cases had, so far as could be ascertained, no treatment of any kind from the commencement of the disease till their death—that is, throughout the entire course of the disease The duration is measured from the time when the patient first noticed the symptoms of disease—namely, the tumour, till death Daland finds the mean duration of the disease to be 40 5 months and the median period—i e, that at which 50 per cent had died—to be 30 months Greenwood's figures, which are based on three separate series, give a general mean duration of 38 3 months (39 8, 39 57 and 32 78 for the several series), and 27 5 and 24 0 months for the median period. Although the two sets of results are very similar, Daland's data show a somewhat longer duration of life, his series however is very much smaller and to that extent less reliable The same feature is shown in the survivorship tables Daland finds 40 per cent, 22 per cent, 16 per cent, and 5 per cent alive at the end of 3 5, 6, and 10 years respectively from the detection of the symptoms, all had died at 13 years Greenwood's figures are 34 per cent, 16 per cent, and 12 per cent at the end of 3, 5 and 6 years In view of the difference in the size of the samples, this is probably as close a correspondence as could be expected, which suggests that the "malignancy" of cancer of the breast is roughly the same in Great Britain and in the East of America Daland also gives some data of results after radical operation for cancer of the breast Of 16 cases without glandular involvement, 62 5 per cent were alive at the end of seven years after the detection of the tumour It is not stated whether any had died of diseases other than cancer, but one had died of operation These figures are not so favourable as those published last year[3] for the Leeds cases Out of 39 patients without glandular involvement, 30, or 77 per cent, were still alive at the end of ten years after operation, and of the nine deaths six had been due to causes other than cancer All series of cases are valuable which show the fate of patients at long periods after operation for mammary cancer. So far as they have been published they show how favourable are the results obtained with radical operation at a time when the growth is still confined to the breast

DEVELOPMENT OF LOWER PART OF VAGINA

Much argument has centred round the vexed question of the development of the lower part of the vagina, which has seemed to anatomists, and more indefinitely to clinicians and pathologists, to differ in certain particulars from the upper portion of the tube. It has been derived by individual workers from the Mullerian ducts, from the dilated ends of the Wolffian ducts, from combinations of both these structures, or from the urogenital sinus, either above or in combination with one of the varieties of ducts just mentioned It has, moreover, been described as growing *in situ*, and as extending down secondarily and freely to assume its ultimate position and opening At a meeting of the Anatomical Society held on Feb 4th at St Mary's Hospital Miss Alice Bloomfield and Prof J. E Frazer brought forward a first account of the results of their observations by serial sections on purely human material, showing that, up to the time when its presence is variable and it frequently disappears altogether, the Wolffian duct is distinct from the Müllerian duct, and shows no sign whatever of growth or bulbous formation They showed the lower end of the vagina to be purely Mullerian in its development, in the course of which it extends along the wall of the urogenital sinus and invaginates this to a considerable extent, producing the evaginated hymen in the relatively shortened sinus This simple account not only explains many of the features met with in the fœtal condition, but is in keeping with what might be expected on general morphological grounds

AN AMERICAN EPILEPTIC COLONY.

The Craig Colony in the State of New York is famous among institutions for the care of epileptics, and Dr William Shanahan the medical superintendent always has some shrewd observations to make upon the care and treatment of his patients—observations which it would be useful to publish in the form of a book A few facts taken from the thirty-third annual report will indicate how large is the experience which the colony offers and how ambitious is the work done There is now an average population of 1586, with nine resident, three visiting, and nine consultant physicians. The net cost per patient is 324 dollars a year or nearly 26s per week, and in this report Dr Shanahan asks for capital alterations and additions to the value of £300,000. Among more critically sceptical attitude a drawback to the public weal? There are some who think that direct instruction of the British public on the principles of healthy living ought to be given more systematically than at present, and among these are Dr W **Allen Daley** and Miss **Hester Viney**, joint authors of a book on the subject recently published[1] The authors, after describing the kind of education continually given through the routine practice of medical practitioners, private or public, and through nurses, present a moderate statement of the case for special teaching, and set out in a lengthy appendix model schemes, syllabuses of lectures, leaflets, programmes for lecture or health weeks, and lists of films which may be used as the skeleton of propaganda campaigns We are glad to find their enthusiasm qualified by a warning against the risk of vulgar advertisement methods, while the recognition of the fact that the ideal place for health-teaching is in the curriculum of the ordinary school is welcome In their view that health should not be taken as an isolated subject, but the whole curriculum of the school thoughtfully studied before the classes begin, and the health classes correlated with the rest of the subjects taught, we can trace the steadying influence of Sir **George Newman**, but if the children are to be guided from day to day and hour to hour, as the occurrences of school life afford the opportunity, every teacher ought to have sound and up-to-date training When this occurs no doubt health in industry will improve beyond belief, meantime the Industrial Health Education Society has a great task before it

THE LISTER CENTENARY.

The provisional programme for the Lister Centenary celebrations has now been agreed The celebrations will commence on Monday, April 4th, with the reception of delegates by H M the King at Buckingham Palace, and on the evening of that day a reception will be held at the Royal Society of Medicine, when Sir **StClair Thomson** will give an address On Tuesday, April 5th, at 11 30 A M, there will a reception of delegates by the Prime Minister and a presentation of addresses at the House of the British Medical Association, applications for tickets to the ceremony may be sent to the secretaries of the Royal Society at Burlington House or to the British Medical Association There will be short discourses by three delegates from abroad, dealing with the effect of **Lister**'s work on surgical and pathological science and practice in their countries In the afternoon of that day there will be a conversazione at the Royal College of Surgeons, England, and in the evening a dinner with the Merchant Taylors' Company at their hall On Wednesday, April 6th, there will be a memorial service in Westminster Abbey at 11 15 A M, when an address will be delivered by the Bishop of Birmingham, the Rt Rev E W. **Barnes**, F R S In the afternoon there will be a meeting at the Royal Society of Medicine at 3 P M, when discourses will be delivered in the Robert Barnes Hall by Sir **Charles Sherrington**, Prof W **Bulloch**, and Sir **Berkeley Moynihan** In the evening there will be a conversazione at the rooms of the Royal Society, Burlington House Arrangements have been made that ladies should be present at all these ceremonies except at the dinner on the evening of April 5th There will be an information bureau in the rooms of the Royal Society where tickets for the various receptions and ceremonies will be issued to the official delegates The bureau will be open on Saturday, April 2nd, and Sunday, April 3rd, from 10 A M till 5 P M The bureau will also be open from 9 A M on Monday, April 4th, but it is hoped that as many delegates as possible will present themselves at the bureau with their credentials, not later than Sunday All communications should be addressed to the secretaries of the Royal Society, Burlington House, London, W 1

A Lister Exhibition in the Wellcome Historical Medical Museum, 54A, Wigmore-street, will be open for inspection by the delegates, daily, 9 30 A M to 6 P M, from Monday, April 4th, until further notice

Annotations.

"Ne quid nimis"

DENTAL CARIES IN BABIES

To all workers in children's hospitals and infant welfare centres the spectacle of children of 2 or 3 years of age with extensive caries of the teeth is a familiar sight, but among dentists the ætiology of this early decay has not received much attention, probably because neither the private practitioner nor the school dentist sees many children so young In a recent paper[1] Mr A T Pitts describes some valuable investigations at the Hospital for Sick Children, Great Ormond-street For the sake of completeness the carious teeth extracted from each child were examined microscopically so that their minute structure could be correlated with the clinical data Many parents, he says, stated that the teeth came through the gums already decayed, and, though this cannot be correct as a statement of fact, it may, he suggests, have an element of truth in it and possibly signifies some congenital defect of structure which renders the teeth more liable to caries Such a view has been strongly urged by Mrs May Mellanby as the result of her experimental work Children under 3 form about 7 per cent of those attending the dental department of the Hospital Though this does not represent the true incidence of caries at this age, since all the children are brought on account of various kinds of dental disease, yet it shows that in babies the condition is not negligible Indeed, some figures obtained by Dr Ethel Dukes from an infant welfare clinic showed a much higher percentage, for out of 84 children under 3 years old, 22 had carious teeth The teeth usually affected are the upper incisors, the caries may start on the labial surface and extend toward the cutting edge or, more rarely, may start on the cutting edge itself and progress upwards to the gum margin Sometimes this latter type of caries may cause a definite notch

Mr Pitts suggests that damage to the incisors may be mistaken for the stigma of congenital syphilis, known as Hutchinson's teeth, which would account for the statement that occasionally Hutchinson's notch occurs in the temporary teeth The resemblance, however, is only superficial and Mr Pitts has never seen a true syphilitic notch in the temporary dentition In 29 per cent of the children examined the mothers stated that the teeth were defective on eruption, and though in only a few cases were there any visible sign of defective structure in the other teeth, it is thought that the mothers' statements should not be entirely disregarded The majority of the children were breast-fed, many of them for long periods, and there seemed to be no correlation of the caries with either breast or bottle feeding It was often found that a dummy comforter had been used, frequently with some sugary or carbohydrate substance to help its soothing action The substances most commonly employed for this purpose were virol, condensed milk, and honey It is noteworthy that E H Harries[2] in 1911 drew attention to the rapid myocardium in heart disease was of greater importance than the nature of the valvular lesion, a conception that was further realised by the late Sir J. Mackenzie. Cardarelli cultivated science for its own sake, not for the satisfaction it can give to those who follow its teachings but for the gladness it can give when applied to the betterment of human life. As Prof Maragliano has said of him in a recent obituary notice in the *Riforma Medica*, "If the human body of Antonio Cardarelli is now lifeless and lovingly returned to the bosom of his native land his spirit remains the eternal symbol of a teaching that should never be forgotten in the Italian Schools"

PSYCHICAL RESEARCH

WE have received the first part of Vol I. of the Proceedings of the National Laboratory of Psychical Research, established in South Kensington for the scientific investigation of alleged abnormal phenomena and forming the European headquarters of the American Society for Psychical Research Starting with no preconceived theories the Council will endeavour to ascertain and demonstrate the laws underlying psychic or abnormal manifestations, and they emphasise the fact that every person connected with the laboratory is, by personal investigation convinced of the reality of physical and mental phenomena, apparently abnormal, for which a normal explanation cannot be found The present fasciculus is wholly occupied with an account of the telekinetic and other phenomena witnessed through Eleonore Zugun, a Roumanian girl 13 years old who, in her own view and in that of her friends at home, is possessed of a familiar spirit which plays all sorts of strange and useless tricks when she is about The girl is described as healthy, very intelligent and happy, and appears to enjoy nothing better than playing with clockwork trains; while she is doing this in the passage, a halfpenny which has been put on the mantelpiece in a neighbouring unoccupied room may quite likely be moved to the far corner of the room Dracu as the devil is called, did not eat the biscuits which Eleonore thoughtfully left for him (or her or it) in the laboratory overnight but he seems to have quite a habit of biting the girl and his teeth marks may suddenly appear at any time as white wheals And so on The whole forms a narrative which will confirm those who believe in their faith and will entirely fail to carry any conviction to unbelievers; it is an example of what has been done over and over again during the last 40 years or so and brings us no nearer a solution of the problems. For few serious-minded people will deny that psychical research has really produced problems of a fundamental character which we should all like to solve; but whether their spiritual significance can be elucidated by this material technique is very doubtful. Meanwhile it is evident that a subject who shows factitious urticaria as well as Eleonore does might well be passed on to Sir Thomas Lewis and his collaborators

RATIONALE OF WASSERMANN REACTION

ALTHOUGH brought to birth as the result of a satisfying system of ratiocination, the Wassermann reaction has in these latter days come to be recognised as a sort of diagnostic trick. Its usefulness is less than ever disputed, but why the serum of a syphilitic patient should give a positive reaction—which once seemed so easy to explain—has become shrouded in deeper and deeper mystery Even the invention by American workers of a hypothetical substance, "reagin," has thrown no real light on the facts, nor has the substitution of the term "immune serum" for the hallowed name of "amboceptor." The problem has lately been attacked from a somewhat unusual angle by Ameer Khan,[1] working in the laboratories of the Brooklyn State Hospital He sees the whole reaction in terms of hydrogen-ion concentration, and though a good deal more in the way of experimental proof is required to support the considerations which lead him to this view, his results so far as they go, are nevertheless interesting The Wassermann reaction, he believes, should be interpreted as a reversible chemical reaction dependent on the proportions of free H and OH ions present in the elements employed: a positive result he regards as due to a preponderance of H ions and a negative to a preponderance of the OH ions As the only variables in a properly carried out series of Wassermann reactions are the sera under investigation, it would follow from this hypothesis that the change in the blood of syphilitic patients must be an alteration in distribution of the inorganic radicles, giving rise to a preponderance of acid ions Such an alteration in a highly buffered substance like blood need not give rise to any actual change in pH, but it might lead to some change when the conditions of the buffering are altered, as in the Wassermann reaction, by mixing the blood with other test ingredients. No investigations on this point are recorded in Ameer Khan's paper.

TRANSFUSION

THERE are probably few therapeutic procedures which have a basis more securely founded on sound physiological and pathological knowledge than transfusion. We welcome, therefore, the very thorough review of these fundamentals which is contributed by Dr. C A. Doan from the Rockefeller Institute to the current number of that useful periodical *Physiological Reviews* (vol vii, p 1); his bibliography includes 717 items and he gives a critical summary of the whole The outstanding clinical point is that nothing can replace the direct testing of the bloods of donor and recipient against each other if the operator is as anxious as possible to avoid anything like an accident. A number of workers in recent years have found anomalous bloods which do not fit into the established scheme of classification into four types, and these instances are now so numerous (though relatively, of course, quite rare) that it is certain that they cannot be put down to slipshod technique. It is also plain, as Prof E. E Glynn and Dr A. R. Jones recently emphasised,[1] that the "universal donor" cannot be used indiscriminately; some of them have such a high titre of agglutinins in their serum that it may cause agglutination even when it is diluted in the blood stream of the recipient. The third agglutinating factor which was identified by Guthrie and Huck has been examined on a large scale at Sheffield by Dr F. W. Simson[2]; it complicates the normal grouping in a minor way though it is of more theoretical than practical importance. Preliminary grouping by type sera should, therefore, always be checked by direct testing of the two parties to the transfusion against one another. Dr. Doan's survey brings out two other conclusions from the now considerable mass of experience: that though it may occasionally prolong life in e g., pernicious anæmia, transfusion finds its real use in the replacement of blood lost by hæmorrhage and that it is best and most conveniently done by the citrate method and any simple apparatus Along broader lines the outstanding feature of recent work is the suggestion of Bernstein, Snyder, and others that the facts of the groups and their inheritance are best explained by an assumption of three heritable factors instead of the two originally proposed by Donath and Landsteiner. It certainly seems as if the anthropological data, which have so far given rather disappointing results, are more reasonably interpreted on the new scheme and may yet throw light on the origin and relationships of human races.

[2] Ibid., p 279

than 5000 cases which have been discharged or have died since the colony was started, there has been a recovery rate of 3 2 per cent , the standard of recovery being freedom from seizures for at least two years The most interesting feature of the report is a bold attempt at an ætiological classification of the last 1500 patients admitted Among every 100 such patients the disease is supposed to have originated in 12 cases from "inflammatory cerebropathics" (meningitis or encephalitis), often arising as complications of an acute specific fever; in 11 cases the assigned cause is heredity, in 10 cases developmental defect, in three cases trauma at birth, in five cases trauma since birth, in two cases cerebro-vascular sclerosis, and in two cases syphilis, hereditary or acquired Of great interest are two other groups; 5 per cent are reported as cases of essential epilepsy, due to "personality make-up," and 4 per cent as endocrinopathic Only 43 per cent of cases remain as unclassified The figures given are only a summary of results, and it is difficult to make any comment without some knowledge of the methods adopted in arriving at them Nothing is said of multiple factors in any given case, but we assume that in each case an effort was made to select the major factor, and that it is upon these major factors that the classification is based It is to be noted that the investigation is an endeavour to state cause and effect The endocrine conditions and the developmental defects, for instance, are here cited not as concomitants but as causes of epilepsy We hope that Dr Shanahan and his collaborators will republish these figures in fuller detail and with some account of the methods adopted in classification The numbers are large, and the records, doubtless, thorough and complete Explained, considered and discussed, the figures should prove a valuable aid to all who are seeking to understand epilepsy Among other information given in the report it may be noted that the incidence of tuberculosis is higher than might be expected, for during the last five years tuberculous infection was present in 86 patients who died More surprising still is the fact that among the last 165 deaths only one was due to status epilepticus Pathological investigations during the year have included researches into the rate of sedimentation of the red blood cells and into the calcium-content of the blood In neither case did the figures for epileptics fall outside the normal limits

THE INJECTION OF FOREIGN INERT PARTICLES INTO THE BLOOD

It is known that many blood-cells on contact with a non-greasy foreign material are, by capillary action, pulled progressively onward over the foreign surface, like a drop of water on a stone To such cells, which include mammalian platelets and certain cells of the blood of astacus, Prof J Tait has given the name of thigmocytes They are not distorted by contact with an oily or greasy surface, and are highly phagocytic towards minute particles of non-greasy matter They have the power to ingest very minute particles of insoluble material without apparently suffering cytolysis, and are also a source of thrombin The platelets or hyaline thrombocytes of mammals are peculiar in at least two respects, in their small size and in apparent absence of a nucleus In the course of some experiments recorded in the *Journal of Physiology* (No 2, December, 1926, vol lxii) Tait, working with A R Elvidge, injected some excessively fine particles of fused quartz, and particles of Indian ink and other inert substances such as barium sulphate and carmine, into the ear vein of rabbits *A priori* considerations seemed to indicate that an injection of very fine particles might fail to cause coagulation of the circulating blood, whereas an injection of coarse particles might cause coagulation It was found on intravascular injection that even coarse particles did not necessarily determine thrombosis Addition of coarse particles to paraffin-held, drawn blood, by causing cytolysis of thrombocytes, eventually caused coagulation Addition of an adequate quantity of fine particles to the drawn blood of the frog similarly caused coagulation, while addition of a smaller quantity of fine particles did not Admixture of particles with the circulating blood while failing to cause thrombosis, nevertheless effected a transformation of fibrinogen into fibrin According to the observers the reason why thrombosis does not occur is that the particular conditions of formation of the fibrin allow of a successful response on the part of the "natural antithrombic mechanism" of the circulation However the thrombosis may be brought about, it would seem likely that the rate of injection of the particles is the important factor Rabbits will tolerate the intravenous injection of a thick suspension of fine particles of silica with no apparent ill-effects, provided the injection is given fairly slowly A rapid injection, however, is prone to be followed immediately by convulsions and death Tait and Elvidge report that as a result of intravascular injection of particles a fall in the number of circulating platelets occurs After a heavy injection the fall is profound (though complete disappearance was never observed), and some days elapse before the previous number is restored With injection of a smaller amount the fall of platelets is less and the time for recovery of the initial number is shorter By repetitions of the injections at intervals less than the time necessary for recovery the number of circulatory platelets can be kept low S P Bedson,[1] however, investigating the relationship of the reticulo-endothelial system to the number of circulating platelets, has shown that blockage of the splenic endothelial cells by carbon causes a considerable increase of platelets in the blood He suggests that the spleen regulates the number of circulating platelets by phagocytosing the old and effete elements, these findings are diametrically opposed to those of Tait and Elvidge, and the matter is clearly in need of further investigation.

ANTONIO CARDARELLI.

With the passing away last month of this great clinician at the advanced age of 96 years, Neapolitan medicine has lost the most brilliant star it has possessed in the last half century It seemed almost as if the wings of Death feared to touch this grand old man who, old as he was, suffered from none of the drawbacks of age, and preserved a wonderful freshness of interest; but at last the summons came and was heard with calmness and composure. Antonio Cardarelli was born on March 29th, 1831, at Civitanova del Sannio, his father being a much-respected provincial doctor. In 1890 he was called to the chair of medical pathology at Naples as successor to Arnaldo Cantani He was at one time a member of the Chamber of Deputies and became famous for his crusades against the high price of salt, alcoholism, and university reform, in 1896 he was nominated senator The various rivalries which existed among the professors at the hospital could not do otherwise than bring into prominence the brilliant gifts of clinician and teacher, which were so well harmonised in Cardarelli when he was still young And around the young professor there gathered a large crowd of pupils who were devoted to him and whom he taught with untiring zeal He was the discoverer and exponent of much well-recognised physical technique—for instance, laryngotracheal pulsation in aneurysm, percussion and auscultation of the sternum in affections of the mediastinum, transthoracic thrill in hydatid cysts of the liver, and a method of estimating cardiac efficiency Much interest attaches to his description of a group of morbid signs which he united under the name of cardiac neurosis in which he indicated the true meaning of Basedowian tremor, and signs relating to the pathology of the vagus and a special form (vasomotor) of angina pectoris It was also his conception that the condition of the minute, and in amounts equal to about 20 c cm per kg of body-weight It is repeated if the blood pressure shows a tendency to rise again. For further details the reader should consult this valuable paper, the results of which appear to have received general confirmation

---

[1] Brit Jour Exp Path, vol vii, No 5

Lumbar puncture is another procedure which has been advocated, but according to the authors just quoted it is not without its risks, owing to the danger of a medullary pressure cone phase, well exemplified in their record of a fatal case It should therefore not be undertaken without due precaution and full realisation of its risks

Sedative drugs are valuable only in so far as they supplement and maintain the results obtained by the above methods The best of these are chloral hydrate, in doses of from 5 to 15 gr given every four hours by mouth or 30 gr by rectum and the judicious use of morphine Headache and vomiting are the result of increased intracranial tension and usually respond rapidly to the methods already described.

The treatment of œdema and the general management of these cases are part of the treatment of the causal nephritis.

To sum up, the aim in the treatment should be the prevention of uræmic convulsions by recognising the significance of a rise in blood pressure and taking prompt measures for its reduction

True Chronic Uræmia

This form is the final phase in chronic diffuse glomerulo-tubular nephritis, and is its most frequent mode of termination

Whilst a discussion of the numerous theories which have been advanced to explain the uræmic manifestations is beyond the scope of this article, it is interesting to note that the view put forward by Wilson in 1833 that urea was the responsible toxic substance, and regarded until quite recently as of little more than historical value, seems to be coming once more to the fore. To quote Wells,[2] "It would seem, despite the prevailing opinions to the contrary that it is entirely possible that the manifestations of uræmia may be caused by the known nitrogenous substances that the kidneys have to excrete, and that the only difficult thing to explain is the failure of investigators to consider the time element in experimental intoxication." In other words, it is necessary to record observations on the effects of retained substances when maintained in the organism at the concentration met with in uræmics Definite progress has already been made along these lines Hewlett Gilbert, and Wickett[3] found that if large doses (100-125 g) of urea were given to healthy men in single or divided doses, symptoms occurred when the blood concentration had reached a level of 160 to 245 mg of urea per 100 c cm of blood. These symptoms were headache giddiness, apathy, drowsiness, bodily weakness, nausea, and diarrhœa , in brief, the symptoms of chronic uræmia Leiter,[4] by the slow intravenous injection of urea into dogs, produced similar symptoms, death finally occurring from convulsions, when the amount injected reached an equivalent of at least 1 per cent of the animal's weight in grammes

It seems clear therefore, that we must revise our ideas and accord to urea a much more important role than that of a harmless, inert, waste product Doubtless other factors are of importance in certain cases, as for instance in those in which the blood-urea values lie within normal limits but such are exceptional and it is possible that some of them are examples of pseudo-uræmia and owe their symptoms to the effects of prolonged vascular hypertension rather than to renal failure

The clinical symptoms of uræmia appear insidiously and tend to assert themselves when figures of 150 mg or more of urea per 100 c cm. of blood have been reached When once established the course is progressive though temporary remissions may occasionally delay the fatal termination Treatment is profoundly unsatisfactory. but while we know of nothing to stem the inevitable march of events by the judicious treatment of outstanding symptoms the patient s sufferings can often be ameliorated and the end made easier

Gastro-intestinal Symptoms—In the majority of cases these are amongst the earliest and most troublesome symptoms to declare themselves, and represent the so-called gastro-intestinal type of uræmia The mouth should be kept clean by the frequent use of alkaline washes and all debris from the teeth and gums should be removed after meals to minimise, as far as possible. the risks of uræmic stomatitis Nausea and vomiting are prominent symptoms and contribute largely to the patient's discomfort. Gastric sedatives, such as cerium oxalate, gr v., in combination with dilute hydrocyanic acid and bismuth, ♏x. liquor adrenalin hydrochloride in water, and minim doses of tincture of iodine repeated at frequent intervals are all useful, whilst in especially intractable cases the following may give temporary relief

R Chloretone, gr v
Cocaine hydrochloride gr 1/5
Not more than three doses to be given in 24 hours

Constipation, often a very troublesome symptom, is best dealt with by frequent and large doses of saline aperients in order to encourage elimination of urea by this channel At times, however, a very troublesome and fatal diarrhœa, with all the manifestations of ulcerative colitis, will necessitate the use of suitable astringents and possibly opium

Persistent hiccough, though rare, is of grave import and proves very resistant to treatment Stimulating applications to the epigastrium, such as fomentations or mustard leaves, should be tried, and of drugs, nitro-glycerine gr 1/100, liquid extract of ergot in drachm doses, and carminatives, such as oil of turpentine ♏x in capsules, have their advocates The symptom is usually a terminal one, and there is no reason in obstinate cases to withhold morphine

The diet is not a matter of primary importance at this stage, the time having passed when any benefit could be expected from the rigid limitation of proteins Water should be given freely. and the patient s likes and dislikes consulted

Respiratory Symptoms—Paroxysmal dyspnœa, the so-called uræmic asthma is often a prominent symptom, and on the grounds that this is a manifestation of acidosis sodium bicarbonate. in drachm doses, every three or four hours, may be tried Inhalations of oxygen are useful, but probably the most certain method of relief is the injection of morphine

Cutaneous Symptoms—Itching of the skin, at times of intolerable severity and occasionally associated with various skin eruptions is best treated by the frequent use of warm alkaline baths and sedative drugs such as the bromides in full doses Elimination of toxins through the skin by the various methods of diaphoresis is not to be recommended It adds to the patient s weakness and does no good.

Nervous Symptoms—These consist of a mixture of depression and irritation Mental depression is often extreme and there may be increasing lethargy passing into coma Irritative phenomena are seen in the twitching of muscles and cramps. in restlessness, mild delirium, or even mania Chloral hydrate, gr v–xv in combination with gr xv of a bromide salt is useful, but our sheet anchor is morphine which, as Osler insisted, can be given under careful supervision without undue risk

Persistent headache, if unrelieved by aspirin, phenacetin or the like and especially if associated with a rise of blood pressure, should be treated by venesection or by the injection of a 1 per cent magnesium sulphate solution Convulsions which. though not an essential part of the clinical picture of chronic uræmia may occur in the terminal stage should be treated on similar lines

To sum up treatment of chronic uræmia is symptomatic only, and our end is gained if the sufferings of this lingering malady are in some measure eased For this purpose morphine is an indispensable ally.

SMALL-POX IN MONMOUTHSHIRE AND YORKSHIRE

ON the western side of Monmouthshire there are five industrial valleys draining downwards toward the town of Newport—namely from west to east, Rhymney, Sirhowy, Ebbw, and Western and Eastern Valleys An extensive outbreak of small-pox in these densely populated valleys has come to light during the past week The two most eastern of these valleys are mainly involved in the outbreak, but on Feb 28th a case was reported from Blackwood at the lower end of Sirhowy Valley In spite of the high mountains which separate them from each other these valleys are not far apart The inhabitants, numbering approximately 370,000, are mainly occupied in various branches of the mining industry and there is a great deal of intercommunication The opportunities for spread, therefore, in a population very largely unvaccinated are considerable A case of small-pox was discovered in Cardiff Royal Infirmary on Feb. 18th and removed to the Cardiff Small-pox Hospital The patient had been admitted to the infirmary from Abertillery in Monmouthshire, and the date of sickening definitely excluded a Cardiff infection On the following day another case of small-pox without any association with the first case was reported in Abertillery, and as the result of inquiries instituted by the county and urban district medical officers and a medical officer from the Welsh Board of Health, it was ascertained that a large number of similar cases were occurring in the area surrounding Abertillery Altogether up to Monday, Feb 28th, 40 cases had been discovered and dealt with The towns and villages affected are Garndiffaith, Blaenavon, Abertillery, Talywain, Varteg, Abserychan, Pontnewynydd, Penhow, Pontypool, Newport. The two cases reported in Newport are merely suspects

Monmouthshire County Council, who are the responsible authority for the isolation of small-pox, have no adequate isolation accommodation for this disease, and it has been necessary to utilise beds which Newport and Cardiff Corporations have put at their disposal We understand that further arrangements for increasing accommodation are being made, but it is obvious that an extensive outbreak of this nature will involve the rapid provision of a large number of beds In the meantime active measures for preventing the spread of infection are being taken, and a vigorous campaign is being carried out with the object of getting the population of the affected valleys vaccinated It is understood that the response to the appeals of the Health Department is good In Yorkshire the disease seems to be of a more virulent type The infection has spread to Leeds, while at South Shields nearly 30 new cases were notified, including two nurses Here, also the population is submitting to vaccination on a large scale

THE Cambridge University Press announces the preparation of a new series, "The Cambridge Comparative Physiology," edited by Prof Joseph Barcroft, F R S, and Mr J T Saunders, University Demonstrator of Animal Morphology The first three volumes, which will be ready this spring, will be "The Comparative Physiology of the Heart," by Prof A J Clark, "The Genetics of Sexuality in Animals," by Dr F A E Crew, and "The Comparative Physiology of Internal Secretion," by Mr L T Hogben

EPSOM COLLEGE —The Council are about to award a St Anne's Home Scholarship of £52 a year to the orphan daughter of a medical man who has been in independent practice in England or Wales for not less than five years Candidates must be fully 7 years of age and not over 12 years of age on May 1st next The Council are also about to award a Henry Duncalfe Annuity of £30 a year to the unmarried daughter of a medical man. Candidates must not be under 50 years of age Forms of application can be obtained from the Secretary at the Office of the College, 49, Bedford-square, W C 1, and must be returned not later than the morning of March 16th

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions

CCXIII —THE TREATMENT OF URÆMIA

URÆMIA is an unsatisfactory term, including as it does symptoms diverse alike in mode of onset, ætiology, and pathology, and having but one thing in common—namely, their occurrence during the course of renal disease and in conditions associated with anuria Uræmia may be regarded as the expression of a temporary or permanent failure of the kidney in one or other of its functions The clinical manifestations are divisible into two well-recognised groups—a convulsive type occurring mainly in acute nephritis and tending to recovery, and a chronic type occurring as the terminal phase in chronic nephritis and indicating a kidney defeated beyond all power of repair Mixed forms are occasionally met with, but generally speaking the two groups are quite distinct A third type has been separated off by Volhard, and called by him pseudo-uræmia which, while resembling chronic uræmia in certain of its manifestations, is unattended by any evidence of renal failure, and is probably due to the effects of prolonged vascular hypertension The treatment of this group is outside the scope of this article

Acute Convulsive Uræmia

This form occurs as a complication of acute glomerulo-tubular nephritis and occasionally in those chronic parenchymatous forms associated with œdema, now more accurately designated chronic nephrosis

It may be regarded as due to over-action of the compensatory mechanism following failure of the kidney to excrete water and salts Since evidences of urea retention in anything but a moderate degree are wanting, the condition is not strictly uræmic and would perhaps better be classified as the cerebral symptoms of acute nephritis The underlying cause is in all probability compression of the brain against the rigid cranial wall by cerebral œdema, a theory which, originating with L Traube and lying discarded for many years, has now been revived Invariably associated with it is a rise in blood pressure, whose relationship to cerebral compression has been shown in the experimental work of H Cushing and the clinical observations of K Blackfan and B Hamilton Whilst the epileptiform attack is the classical expression of this type of uræmia certain rudimentary forms or, as Volhard calls them, eclamptic equivalents, may be substituted Such are headache, vomiting, localised paralyses or hemiplegia, sudden blindness, hemianopia, and various mental disturbances such as hallucination, delirium, and acute mania A prodromal stage, during which the blood pressure is rising, can be recognised, and is a valuable indication for treatment

Venesection —Acute convulsive uræmia is a medical emergency and demands prompt and adequate measures Frequent readings of the blood pressure during the course of acute nephritis will usually give warning of impending catastrophe, which may be averted by a timely venesection The removal of from 10 to 20 ounces of blood is a measure of proved utility, and should be resorted to without delay, either as a preventive measure or when convulsions have occurred

Intravenous Magnesium Sulphate —Recently Blackfan and Hamilton[1] have recorded a method which, they claim, is superior to any other in the treatment of this condition in children

These authors confirm the occurrence of cerebral œdema and the rise of blood pressure, and find that the intravenous injection of a 1 per cent solution of magnesium sulphate, together with the administration of large doses of the salt by mouth and by rectum, results in a prompt fall of blood pressure and a subsidence of cerebral symptoms The injection is given very slowly, not more than 10 c cm per than between ordinary twins in respect of tooth eruption, of occlusion, and of the occurrence of gingivitis; but the relationship is no closer in one group than in the other in respect of caries in permanent teeth and of hypoplasia He has assisted Mrs Forest Smith in the statistical treatment of the data for a report on Rheumatism shortly to be published by the Council

---

[1] Blackfan, K, and Hamilton B Boston Med Jour 1925, cxcii, 617

Dr Young has investigated the incidence of cancer in the different districts and has assisted Dr Clara Stewart in a statistical analysis of the post-operative histories of hospital patients at Leeds which appeared in THE LANCET 1926, ii , 1258, while Mr W T Russell's study of the influence of fog and temperature on the respiratory death-rate among adults is also familiar to our readers [1]

The Statistical Committee of the Council over which Dr Major Greenwood presides have taken a large share in three industrial researches, concerned respectively with the mining, the weaving, and the printing industries, to which detailed reference is made in the Report of the Industrial Fatigue Research Board

The Dick Test for Scarlet Fever Immunity

At the City Bacteriological Laboratory in Birmingham Dr H Henry and Dr F C Lewis have continued their researches into scarlet fever immunity

By using susceptible human volunteers they have been able to titrate a measured amount of scarlet fever toxin against varying amounts of serum taken from children who have not had scarlet fever and also from those who are convalescent from the disease, and, by this method, have succeeded in showing that an attack of scarlet fever usually results in an immunity of which the degree can be measured in terms of antitoxin units

It has also been discovered that a small percentage of young children have notable quantities of antitoxin in their blood, without any other evidence of any previous attack of the disease The deduction is that these children must have passed through an attack of the disease in a form not recognised clinically Since most adults are resistant to the Dick test and also show relatively large amounts of the same antitoxin in their circulating blood without any history of an attack of the disease, a strong suggestion arises that scarlet fever as the clinicians see it may exhibit only a small percentage of a widespread infection which at present escapes detection

Dr Henry and Dr Lewis have also made a series of experiments to determine the rise and fall of antitoxin production in convalescence from scarlet fever At present their work is being directed to a satisfactory standardisation of the Dick test and to an accurate definition of the antitoxin unit In dealing with both these important problems they are acting in collaboration with members of the Council's staff at the National Institute

Diseases of the Excretory System

A record of the kidney efficiency tests, by which the progress of a large number of cases of chronic nephritis has been followed since the war, has been maintained during work done for the Ministry of Pensions This has now been completed, and the results are being correlated The investigation shows many interesting and sometimes quite unexpected results, it will give a real basis for knowledge and should prove a useful record of the possibilities of prognosis of the clinical progress in nephritis of a kind hitherto not available

At Guy's Hospital, London, Dr A A Osman has received a part-time grant for studies of nephritis which have given results of great promise His previous work had shown that in all kinds of kidney inflammation there is a fall in the bicarbonates of the blood Proceeding on the lines of a hypothesis based on this, he has worked out and tested a new line of treatment of nephritis by the administration of alkaline salts under particular conditions The results of this treatment, in its present form suitable only for hospital practice, certainly justify further trial and study The method offers at the same time a hopeful line of treatment for the prevention of nephritis following scarlet fever Dr Osman has found evidence for the existence of individuals having a special liability to nephritis after scarlet fever It will be an obvious gain if these can be recognised and given effective preventive treatment

Prof. J Shaw Dunn, working with Dr C J. Polson, has made observations on nephritis due to uranium, for comparison with results obtained earlier in oxalate nephritis, which are in course of publication Dr S L Baker, has again received a part-time grant for work on experimental nephritis, and Dr. Mona Kirkhouse has assisted Dr W E Hume at the Victoria Hospital, Newcastle-on-Tyne, in an investigation into the action of diuretic drugs Dr C Reid of the University of Aberdeen has studied the effect on renal efficiency of lowering the blood pressure in cases of high blood pressure

Vaccinia and Small-pox

Working in the whole-time service of the Council at St Bartholomew's Hospital, London, Dr M H Gordon is continuing his studies of the virus of vaccinia After an examination of the characters of the allied virus of roup, a disease of poultry, the study of vaccinia virus was resumed and an investigation made into the power of the serum of animals immunised against vaccinia both to destroy that virus in vitro and to protect a normal animal against vaccinia

In January, 1926, Dr Gordon served at The Hague upon an international committee appointed by the Health Department of the League of Nations to discuss some problems of vaccination and small-pox A scheme of experimental work was adopted to promote the standardisation of calf-lymph, and the investigation of some of the rarer abnormal results following vaccination

Captain S R. Douglas, assisted by Dr L R W Price, has been engaged in studies of vaccinia, using a strain of neurovaccine obtained by the courtesy of Mr Levaditi from the Pasteur Institute, Paris The experimental work associated with the cultivation of this virus outside the body is still incomplete Many subsidiary points of much interest have already been determined, which bear upon the generalisation of vaccinia in the body and the comparisons to be drawn between the blood-changes and the localised cellular changes in vaccinia and in small-pox respectively

Dr J R Perdrau has studied the possible interactions of the viruses of herpes and of vaccinia upon each other in the same animal, with a view to throwing light on the possibility of post-vaccinal encephalitis, a subject now under special study by the Vaccination Committee, appointed jointly by the Ministry of Health and by the Council

Dr F W Twort, working at the Brown Institution, London, is also attempting to find methods for the artificial cultivation of ultramicroscopic viruses outside the body.

"*Status Lymphaticus*"

During the past year the Committee in charge of this investigation have done the preliminary work necessary to put the scheme on a satisfactory statistical basis

In the past many of the workers engaged in the inquiry have not had the time or facilities for the critical observations necessary to give their data proper statistical value. The Committee have now appointed a number of part-time workers, mostly junior members of the pathological staffs of universities and large hospitals, who collect suitable data according to a schedule laid down by the Committee, and they receive small grants from the Council It is hoped thus to gain uniform and adequate details of the cases under investigation The Committee have also invited the coöperation of other pathologists by means of notices in the medical journals and they have provided an abbreviated form of record card for use The chief objects in view are the collection of a large series of weights and measurements of the thymus in cases of sudden death in apparently normal persons, so as to establish the normal weight of the organ and its proportion to body-weight at all ages the investigation of the associated clinical and pathological states of persons over 15 years who have "persistent" thymus glands and the critical investigation of those cases of sudden and unexplained death where at autopsy the only apparent abnormality is a large thymus

Dr D S Murray has been receiving a part-time grant for work on the thymus gland at the Royal Hospital for Sick Children, Glasgow, and the results are now available In this he has had assistance from the clinical staff, especially Dr Leonard Findlay and Mr. Alexander MacLennan and from Dr J W S Blacklock, pathologist to the hospital, under whose supervision the work has been done

Special Articles.

MEDICAL RESEARCH COUNCIL.

ANNUAL REPORT FOR 1925-26.

(Concluded from p 455)

LAST week we drew attention to the survey of certain branches of research which formed the substance of the introduction to this year's annual report of the Medical Research Council A summary of the work of each department of the National Institute for Medical Research is then set out, while a separate section is allotted to the determination of biological standards and the methods of biological assay. The research work of clinical units is described under the heading of the institution where it is being carried on and then research schemes in specific subjects are considered, systematic cross references being given to work mentioned in another place This list of investigations is worth notice, for it shows how wide is the scope of the research subsidised It includes problems of child life, human nutrition, dental disease, disorders of the cardiovascular system, disorders of the respiratory system, disorders of the excretory system; disorders of the nervous system, mental disorders, the physiology and pathology of the blood; the glands of internal secretion, diabetes and insulin, tuberculosis, studies of the streptococcus and pneumococcus group, venereal diseases, filtrable viruses; canine distemper, studies of cell and tissue growth, malignant disease, radiology and radiotherapy, the biological actions of light, chemotherapy, general biochemical researches, general physiology and bacteriological researches, vision; experimental epidemiology, metazoan parasitology. The term "research scheme" does not here imply that the researches described under each heading are necessarily part of a definite plan, often it is obvious that they are in no way connected, but for convenience are grouped under a common heading On the other hand, the Council calls attention to the coexistence and activity of some 30 scientific committees who contrive without interfering with the freedom of each investigator to frame and supervise some schemes which involve the correlation of results of workers on different aspects of allied problems These committees are composed of experts who give their services, and the Council attribute to this voluntary systematic help the effective and economic distribution of the funds at their disposal Some examples typical of the work in progress are summarised below

Biological Actions of Light

This work continues to be directed by the following committee. Prof F A Lindemann (Chairman), Mr J E Barnard, Dr H H Dale, Captain S R Douglas, Prof Georges Dreyer, Sir Henry J Gauvain, Dr Leonard Hill, Dr J H Sequeira, Dr E Schuster (Sec) The Committee, at the request of the Ministry of Health, have suggested the lines on which reports should be made by the phototherapy department of various institutions receiving grants from the Ministry

Mr J H Jeffree, working under Prof Lindemann and Dr G Dobson at Oxford with a grant from the Council, is attempting to provide simple and accurate means of measuring the energy of ultra-violet rays of different wave-lengths, whether in sunlight or from artificial sources

Dr Dora Colebrook has been appointed by the Council as a whole-time worker under the direction of the Committee, for the organisation of investigations and the standardisation and recording of clinical data To this end an effort is being made by coöperation with clinicians in charge of Light Departments to select for investigation such pathological conditions as show definite and measurable results of the therapeutic action of light, and allow comparison with similar untreated cases for control In a ward reserved for light treatment at the New End Hospital, Dr Colebrook is making a special study of the action of light on chronic ulcers

Dr W S Duke-Elder has been investigating the actions of radiations of different wave-lengths upon the various parts of the eye Special attention is being given to the possible action of natural radiant energy in the causation of cataract Under the general direction of Sir John Parsons, Dr Duke-Elder is conducting an ultra-violet light clinic at the Royal London Ophthalmic Hospital The purpose of the clinic, the first of its kind in the country, is to investigate how far diseases of the eye are amenable to treatment by general irradiation with ultra-violet light, and how far the light can be used in the local treatment of diseases of the front chamber of the eye

Dr R G Bannerman has studied cases of tuberculosis under light treatment at Alton, and done related experimental work

At the National Institute for Medical Research Dr Leonard Hill and his colleagues have continued their studies of the actions of light radiations on the animal body, whether direct or indirect, and have sought to bring these into relation with the practical use of light therapy in clinical work With the aid of glass screens, the transparency of which had been determined by Dr R B Bourdillon, Dr Hill has investigated the wave-lengths of the sun rays which produce skin flush (erythema), and has found that ultra-violet rays of longer wave-length than hitherto supposed are the most active in sunlight He has also, with Dr Y Azuma, investigated the action of ultra-violet rays on skeletal muscle

Mr T C Angus has found, when comparing the effects of arcs between electrodes of different compositions that the killing time for infusoria, the photo-electric cell, and erythema of the skin may indicate very different values of ultra-violet radiation The former two indicators are affected by shorter wave-lengths of ultra-violet light, which do not penetrate the horny layer of the skin and so do not produce erythema This shows the need for some selective screen to be used with these indicators Such a screen is now being sought, the aim being to find a simple indicator of the erythema-producing dose

The Eder photometer has been found inferior to the acetone-blue gauge as a simple means for measuring ultra-violet light The acetone-blue gauge shows that, on the average, two-thirds of the ultra-violet rays are cut off by smoke and dust pollution of the atmosphere in the City of London

Many of the present uncertainties of knowledge, theoretical and practical, spring from the customary use of complex mixtures of radiations of unknown intensity and widely different wave-length Dr Bourdillon has studied the design and preparation of filters for isolating narrow bands of wave-length of ultra-violet rays so as to gain practical methods of using light of any wave-length desired, in bands of few hundred Angstrom units in width, either for research work or for curative treatment Mr Webster's work on the activation of cholesterol by light was referred to in THE LANCET of last week

Dr A Eidinow has made trial of various methods of controlling the dosage of light in clinical work

Statistics

Dr John Brownlee has been engaged during the year, with the help of Mr H E Soper, in making a review of the statistics which are used in medical and biological researches, with a view to publishing a convenient working synopsis of the best methods available for use in inquiries in those fields The work will shortly be published

Dr Brownlee has also been investigating the relation of weather to disease by new statistical methods which have been suggested in recent years These have revealed some periodicities in climatic temperature not hitherto suspected During the year Dr M Young has made for the Dental Committee of the Council a statistical analysis of data collected by Miss F H Bachrach, relative to the dental condition in groups of identical and fraternal twins and has reported on the different degrees of resemblance in dental characters in the two types of twin. The object was to ascertain the influence of the hereditary factor Dr Young has found that a closer relationship exists between identical

THE CENTENARY OF UNIVERSITY COLLEGE, LONDON.

IN connexion with the centenary celebrations of University College four public lectures have been arranged, of which the first was delivered at the College by Prof E H Starling on Feb 28th Sir John Rose Bradford, who presided on this occasion, will himself deliver the last of these lectures on University College, London, and Medical Education on May 13th at 8 30 P M, when Sir George Thane will occupy the chair The intermediate lectures will be given on March 14th and May 2nd respectively, by Sir Oliver Lodge on a Century's Progress in Physics, and by Dr R W Chambers on Philology at University College

Prof Starling took for his subject

A Century of Physiology

He gave a masterly survey of the progress of physiology from the time of Harvey to the third quarter of the nineteenth century, when, he said, the English physiological school might be said to have begun, its beginning being synchronous with the date of the foundation of the Physiological Society—*namely, 1876* He *continued* —

When we are tempted to be annoyed by the abuse and misrepresentation of those who bend their anti-scientific bias in the attempt to prevent experiments on animals, it is well to remind ourselves how much physiology in this country owes to the anti-vivisectionists The antivivisection agitation, which has periodic exacerbations in this country as misguided old ladies leave large sums of money to be expended in such activities, had been especially active in 1874 to 1876 There had been a Royal Commission on the subject, and the first Act legalising and controlling experiments on animals was passed in 1876 It was the persecution and abuse to which the small band of physiologists was subjected that suggested to them the advisability of forming a society for mutual help and protection, and for the interchange of ideas, and after a preliminary meeting at Burdon Sanderson's house in Gordon-square, the Physiological Society was founded in 1876, Thus the Society has till the present time maintained the aims and objects for which it was founded, for mutual friendship and intellectual intercourse among working physiologists In no country in the world do we find all the physiologists as in this country, working as one team, free from all cliques or jealousies, and interested only in helping one another and in advancing the science to which they are devoting their lives From the time of its foundation physiology has advanced in this country with ever-increasing rapidity The Society now numbers over 400 members, and the result of their common labours has been to put the English physiological school in the first place among civilised countries

[Prof Starling proceeded to recall the part played by the Physiological Laboratory at University College in bringing physiology in this country to its present position He spoke of the work of Gaskell at Cambridge, and of Sanderson on the physiology of heart-muscle leading up to the investigations of Ringer and later of Sir Thomas Lewis at University College Gaskell's work on the heart and on its nervous supply led him in another direction the investigation of the sympathetic system, which was continued and developed at University College by Sir John Rose Bradford in conjunction with Bayliss, Dean, and Prof Starling himself He continued —]

Localisation of Function in the Brain

Another important chapter in physiology was opened in part from University College Since the time of Flourens the brain had been regarded as acting as a whole, which no doubt it does, but this force was interpreted as indicating that there could be no localisation of function in this organ and that all parts of the brain had equal actions on, and were equally affected by, all parts of the body In 1870 Fritsch and Hitzig in Germany showed that stimulation of certain portions of the cerebral cortex of the dog's brain evoked movements limited to certain groups of muscles, the muscles affected depending on the locality of the stimulus These experiments were then taken up by Ferrier at the West Riding Asylum and by Ferrier in conjunction with Yeo at King's College, and the fact of localisation was confirmed and extended to the brain of the monkey These researches were the starting-point of a whole number of careful investigations carried out at University College by Schafer, Horsley, Beevor, Mott, and Risien Russell, and at that time the neurological school in England was more fruitful than that of any other country The story was continued by Sherrington, a pupil of Michael Foster at Cambridge, first at St Thomas's Hospital, then at Liverpool and finally at Oxford Sherrington's researches have transformed our conception of the activities of the central nervous system and offer the only reliable basis for a physiological psychology While using the same methods, and inspired by Sherrington's teaching, Magnus, of Utrecht, has built up a conception founded on experimental data of the reflex activities of the lower parts of the brain which, with the results obtained by Sherrington and those of recent years by Pavlov in St Petersburg, give us a working scheme of the whole activities of the central nervous system from their lowest to their highest manifestations From these researches we have obtained an understanding of the manner in which the activities of the body are integrated by the central nervous system in relation with each other and with events in the external world There is, however, another method of integration by which the *consensus partium*, the unity of the whole animal body, is studied—namely, the method of chemical integration When Claude Bernard demonstrated the production of sugar in the liver and found its mother substance, glycogen, he spoke of the sugar as an internal secretion of the liver since it was furnished by the liver for the use of the other organs of the body The recent researches of A V Hill in this College, which prove that the muscle is dependent on carbohydrates and on these alone for the production of the energy of muscular contraction, and the experiments which I am carrying on at the present time with Leonard Bayliss and Muller (which appear to show that the same holds good for the energy of the contraction of the heart) are evidence of the great importance of this internal secretory function of the liver But nowadays when we speak of internal secretion we do not include under this heading the formation of sugar by the liver There is another class of chemical correlations in the body in our knowledge of which, again, the first steps were taken in this College After Gull and Ord had shown that myxœdema was associated with atrophy of the thyroid gland, Horsley, in confirmation of old experiments of Schiff, showed that this condition could be brought about by excision of the thyroid gland and could be removed by reimplantation of a thyroid gland This led to the treatment of the disorder by oral administration of the dried gland, which is now in general use Of the other so-called ductless glands we knew little except what clinical evidence supplied Addison had shown that the disease bearing his name was associated with atrophy of the suprarenals Marey called attention to the association of acromegaly and giganticism with enlargement of the pituitary gland Schäfer and George Oliver in 1895 showed that from both these organs extracts could be obtained which had definite physiological effects, though it was difficult to correlate these effects with those clinical phenomena which had already been associated with atrophy or enlargement of these glands

Secretin

It was not till the discovery of secretin by Bayliss and myself in 1902 that we recognised that these so-called internal secretions were merely isolated

MEDICINE AND THE LAW.

Professional Expulsions

The disqualifications associated with osteopathy are naturally mentioned in an article in the *Solicitors' Journal* of Feb. 12th dealing with the problems of expulsion from a profession or trade-union The article begins with the professions of barristers and solicitors and passes on to summarise the cases decided in the nineteenth century in connexion with the Medical Act It then comments upon *re* Bynoe, a decision of the year 1900 wherein the court held it had no power to direct the rehearing of the case of a practitioner originally disqualified for felony, though admittedly the evidence on which the criminal conviction was based was afterwards found to be unsatisfactory The article suggests that the legislature might usefully reverse the decision in *re* Bynoe and give the court power to direct a rehearing on facts sufficiently strong to warrant it as a matter of justice "It cannot be doubted," the writer continues, "that, had the court possessed this power and been invoked, it would have required the Medical Council to reconsider the case of Dr Axham, and, in view of the latter's last illness, without undue delay" Not everyone, however, will agree that this matter is so free from doubt. What were the fresh facts discovered in Dr Axham's case? His illness, however much we may regret it, was certainly not a fresh fact upon which the disciplinary decision of the General Medical Council could reasonably be reopened in a court of law The *Solicitors' Journal* considers that the Axham case shows the necessity for revising the constitution of the General Medical Council and permitting an appeal to open court from its decisions as in the case of the solicitors' profession The Council, it is said, is too unwieldy a body, the members nominated by outside corporations might be eliminated, the Council should consist of representatives of the profession and persons nominated by the Crown, who should not all be doctors but might include retired judges if the latter were willing to serve Concerning these suggestions, which some will approve, a good deal might be said For the moment there is another passage in the article which is worth quoting The writer mentions Sir H Barker as an unregistered practitioner, a quack from the point of view of the Council, and yet "found by the public to be a brilliant healer in his own line," later honoured by the King with a knighthood "It is hardly too much to say," he adds, "that in his particular branch of osteology he has been the leader, and Dr Axham's infamy was to discover his powers before the profession and even before the general public had done so" Against this statement it seems reasonable to enter a little protest If Acts of Parliament are devised to restrain the activities of the unqualified, it is not really possible to relax the restrictions in the case of an individual because of his peculiar, though untested, abilities

It is probable that much popular prejudice is aroused by the words "infamous conduct" They are not confined to the Medical Act They reappear in the Apothecaries Act of 1874, and, with the addition of the alternative word "disgraceful," in the Dentists Act of 1878 Disgraceful conduct is made a ground for removal from the Register in the Veterinary Surgeons Act of 1881 The expression "infamous" has a rather archaic sound, if it were eliminated some other expression must be substituted to convey the idea of conduct which is professionally dishonourable and reprehensible in a marked degree. No one, surely, quarrels with the principle that a profession should have power to define its own traditions and standards and to enforce them The tendency of to-day is to extend this principle rather than to restrict it Architects and members of other professions are seeking statutory powers of this nature In the last few days there has been presented to Parliament an Engineers Bill "to provide for the registration and to regulate the qualifications of engineers" The Bill proposes to give power to remove an engineer from the Register "owing to conviction of any heinous offence or to unprofessional conduct of a serious nature" Infamous, disgraceful or merely serious, every profession knows the kind of conduct it reprehends and the necessity of some system of discipline

Osteopath's Unsuccessful Claim for Fees

Nobody can recover fees in a court of law "for any medical or surgical advice, attendance, or for the performance of any operation" unless he is a registered medical practitioner Does this principle, which is to be found in Section 32 of the Medical Act of 1858, apply to osteopaths? Does an osteopath give surgical advice and perform operations? The answer to these two questions is apparently in the affirmative The deputy county court judge in the Bloomsbury Court decided on this ground against an osteopath's claim in a case reported in the *Times* of Feb 25th The plaintiff had been called in to give osteopathic treatment to the defendant's wife He stated that he found her suffering from nervous debility and facial neuralgia He found that one of her legs was longer than the other, which fact, he considered, contributed to the debility His charges were 3 guineas for each consultation, and 2 guineas for each subsequent visit His total claim in the county court was £30 9*s* He stated that he obtained his degree in America, that no degrees were conferred in respect of osteopathy in this country, and that he made no claim to be legally recognised The defendant pleaded that the treatment was unnecessary and unsuitable and that the plaintiff was not qualified. The deputy judge referred to the section of the Medical Act already quoted and doubted whether the plaintiff was not debarred thereby from recovering fees, the fees being charges for medical or surgical treatment The plaintiff replied that he believed it had been held that osteopaths could recover, they did not claim to give medical or surgical treatment The judge said it was not a question of what osteopaths claimed to do, but of what they in fact did He gave judgment against the plaintiff, though willing to give leave to appeal if desired Of course, as the judge observed, if an osteopath obtains payment of his fees in advance, the Medical Act does not to this extent apply

Electrical Treatment by Automatic Machine

Two automatic machines were installed in the shop of a Birmingham confectioner and hairdresser They were called "Pickwick Automatic Electric Amusement Machines." In the centre of one of them (produced for inspection in the Court of Criminal Appeal) was this inscription —

> "Place ½*d* in slot and grasp knobs for electric treatment Medically recommended for the following complaints nervousness, neuritis, lumbago, neuralgia, rheumatism, sciatica"

The coin being placed in the slot, an electrical current was felt by anyone who grasped the knobs, but this was not all, for at this point science ended and amusement began By turning another handle the current was switched off and a ball appeared which fell through rows of pegs and passed out through one or six disappearing-places The person who put the halfpenny in the slot had the chance to catch the ball in a cup in its progress before it disappeared If he succeeded, a disc dropped out of another slot which entitled him to repeat the performance and meanwhile to get a packet of sweets or cigarettes The legal question was whether the game was one of chance or of skill In the Birmingham case three persons were convicted of keeping the confectionery and tobacconist business as a betting-house because of the presence of these machines upon the premises, and the Court of Criminal Appeal upheld the conviction It was argued for the appellants that the investor of a halfpenny got primarily an electric shock, and that was the consideration for his investment But the court declined to accept the so-called medical treatment as removing the transaction from the category of gambles

"Audi alteram partem"

THE CANCER PROBLEM AND THE EDUCATION OF THE PUBLIC

To the Editor of THE LANCET

SIR,—At a recent meeting of the Epidemiological Section of the Royal Society of Medicine the possibility of reducing the present mortality of cancer of the breast and uterus was discussed.[1] The openers made out an excellent statistical case in favour of such possibility but received no answer as to its practicability May it not be of value to discover the views of a larger section of the profession?

In attacking a problem of this nature it is obviously necessary to accept facts as they are not as they might be or ought to be; but there seems to be a more or less general tendency to idealise them For this reason far too much attention is paid to surgery in the treatment of the disease Surgery is merely a makeshift It is, perhaps the most efficient method at our disposal in present circumstances, but the terrible mutilation which it causes renders it and must always render it a most undesirable resource In this, as in many other researches, thought follows a beaten track instead of exploring new fields. Hitherto all suggestions have been such as offer little hope of advance

For instance, the common cry is for earlier diagnosis, but no attempt is made to define what is meant by the term In many cases diagnosis can be made at sight the disease is so advanced and in one sense earlier diagnosis is impossible—it could never be made before the patient is seen This should not be considered a matter of earlier diagnosis but of earlier application for advice On the other hand. given the patient, diagnosis is probably already possible as early as it is ever likely to be Cancer is a steadily progressive disease, apparently purely local in its origin, but sooner or later spreading to distant parts There is good reason to believe that the malignant process may be in existence for some considerable time before symptoms or signs of any kind give warning of something amiss Consequently in a large proportion of cases it may well be (and it seems to me that it certainly is) that by the time diagnosis is possible the disease has spread so far that cure is impossible This is not. and is not intended to be an argument against making every effort to establish a diagnosis in the earliest stages; it is a very strong argument against expecting by this means to effect any great improvement on the present results of treatment; and a still stronger argument against focusing attention too strongly upon this method, and not seeking everywhere for a better Even should some serological or biochemical test eventually be found whereby cancer may be certainly diagnosed the difficulty will not be overcome for the test will only be applied after the appearance of some clinically suggestive evidence has been found It thus follows that not early diagnosis (in the above sense) but early applications for treatment should be considered the more important factor at the moment And how can this be brought about? Only in one or both of two ways—viz, by education of the public and education of the profession

Compulsory education has failed to enlighten the ignorance of a large part of the public voluntary education must fail in an even larger part Many could never be educated many more have no desire to be educated and even of those who could be educated many would remain uninfluenced because of other considerations In speaking of malignant disease of the breast and uterus apart from the modesty of sex which education might to some extent modify fear plays a large part in preventing recourse to a doctor—fear of the operation which the woman expects to be recommended; fear, even of having her suspicions confirmed, and learning that what she suspects to be cancer is so in fact Not a few would prefer to live in a fool s paradise and try to persuade themselves that all is well rather than know the truth That any considerable number of women who could be taught by such educational methods, are now ignorant of the significance of certain symptoms and signs I find it difficult to believe But even if by this means, only a life here and there is saved then it is worth while doing To organise a plan of public instruction, to teach all that is possible, to do everything practicable to induce patients to seek early advice is highly desirable, but we must not expect the results to be apparent as a great fall in the mortality from cancer.

Nor does education of the medical profession offer much hope, for practitioners, as a body are already hard-working conscientious and substantially accurate in their knowledge But difficulties are meant to be overcome. and clearly anything that can be done by education should be done thoroughly and without delay Nothing in this letter is intended to encourage the adoption of an attitude of idleness and despair On the contrary, its whole aim is to direct attention to the fact that so far little has been done to solve the problem and that little can be done along the lines generally followed and to urge the necessity for more investigation the opening up of new ground

Pessimism is apparently not popular in this connexion so much that might be said I leave unsaid In one direction at any rate. optimism appears justified Of recent years enormous advance has been made in the investigation of the cause of cancer The part played by chronic irritation has been thoroughly established But more must be done Is all cancer the result of irritation? And what are the irritants responsible? That both these questions will in time be answered there is no reason to doubt and the answer is the crying need of the moment I do not by any means hold that once the cause is known a cure will follow but it should prove possible by removing the cause. by preventing its coming into action, to prevent the development of the disease

What is required, then, is research and more research. by thoroughly competent workers into the causation of cancer · for only thus is it probable that any material decrease in the present mortality of the disease can be effected Much is already being done but much more might be done by those who are at present hampered and restricted by inadequate accommodation and insufficient assistance for the proper carrying out of their work Until some more profitable line can be discovered. it is to this end. it seems to me that effort should be chiefly directed

I am, Sir yours faithfully.

STANLEY WYARD

Upper Wimpole street W, Feb 27th 1927

THE BLOOD-GROUPS OF "IDENTICAL TWINS"

To the Editor of THE LANCET

SIR—May I bring forward still another point of great interest suggested by the correspondence under the above heading I have wondered for a long time past—as, doubtless many others have. though I have never actually seen the suggestion anywhere—whether an antagonistic "blood-grouping" of the fœtus can possibly account for eclampsia or other pregnancy toxæmias? Until Mr. Geoffrey Keynes s letter appeared in THE LANCET (Feb 26th) I did not know definitely that the blood-groups of mother and fœtus were sometimes different. but this being so it does not seem unreasonable to suggest that when this factor is present we have a very possible focus of pregnancy toxæmia It would be helpful to know if any research has been undertaken upon this point

I am, Sir, yours faithfully

Bath Feb 25th 1927 DOUGLAS A MITCHELL.

---

[1] THE LANCET, Feb 5th, p 303

examples of a great system of correlation of the activities, chemical and otherwise, of different organs, not by the central nervous system but by the intermediation of the blood stream, by the discharge into the blood stream of drug-like substances in minute proportions which evoked an appropriate reaction in distant parts of the body When we were investigating the conditions which cause the secretion of pancreatic juice, it had long been recognised that this juice is poured out into the intestine as the semi-digested food from the stomach enters the intestine The secretion of pancreatic juice was regarded as analogous to the secretion of saliva, which is poured into the mouth when food is taken into this cavity, and so assumed, like the latter, to be due to a nervous reflex We found that the introduction of acid into a portion of the small intestine entirely free from any nervous connexion with the rest of the body evoked a secretion of pancreatic juice This must, therefore, have been due not to a nervous reflex but to a messenger of a chemical nature carried in the blood stream, which was the only means of communication between the loop of intestine and the pancreatic gland This chemical messenger we found in fact to be produced in the mucous membrane of the gut and discharged into the blood stream under the influence of acid We called the body *secretin* and recognised that it was only one of a large class of similar bodies which function in the chemical correlation of the different parts of the body

[Prof Starling referred to the other hormones since described and to the other substances equally essential to the carrying out of the normal functions of the body, known as vitamins, and proceeded as follows —]

At the present time the volume of work being carried out in the Physiological Department with the greater facilities placed at our disposal by the gift of the Rockefeller Foundation is greater than at any previous period of the College history Men and women are constantly engaged in research in the physiological and biochemical departments There is probably no subject which I have mentioned in my review of the work of the last 50 years which is not the subject of investigation In my own department I have returned to some of the questions which agitated Harvey and which he left for "future inquiry"—namely, the method by which the heart can adapt its marvellous activities to the needs of the body as a whole, so that it can beat fast or slow, at a high or a low blood pressure, and alter its output and the volume of the circulation six to ten times, according to the activities of the body, and especially according to the muscular activities In this, as in every other investigation of an organ, we must proceed by analysis and by synthesis First isolate the organ and, keeping it alive, study its powers and its reactions to such mechanical and chemical conditions as may be imposed upon it in the body Thus one by one we have to reconstruct the influences to which it is subject in the body, chemical and nervous, and out of our experiments build up a picture of the total of its reactions as they occur in the intact animal We have seen in this way how to a large extent the power of adaptation is inherent in the properties of the muscular wall of the heart itself, but how under ordinary circumstances this mechanism is economised and anticipated by the action of the nervous system, which can quicken or slow the rate of the heart, raise or lower the blood pressure, increase or diminish the force of contraction in accordance with impulses proceeding from the heart, from the arteries, from the periphery of the body, as well as from the cerebral hemispheres themselves It is especially to Anrep that we owe the elucidation of the reflex mechanisms for the control and regulation of the heart's action

But it is with the past, not the future, of physiology and the physiological department of the College that we are to-day concerned That past is full of promise and our actual gains bulk little in comparison with what we hope and expect to achieve So I would take exception to a recent description of the present time as the "golden age of medicine." We associate "a golden age" with an epoch of great achievement which then dies away and comes to an end But physiology and the science of medicine have hardly begun As I have pointed out, the greater part of the physiological edition of to-day dates from the last 50 years, and has been raised within the lifetime of many of us And every year more workers and greater powers are enlisted in the service of research, so that the rate of increase of knowledge grows in geometric proportion Nor can we foresee any time at which this growth can come to an end It is not like the town of Babel, erected as a monument of arrogance and vanity and brought to an end by a strife of tongues Unless the scientific worker approach his task with humility and self-abnegation—the brick he would contribute to the giant edifice of science crumbles away even before it is in position And the strife of tongues is impossible, for science throughout the world has but one language—that of quantity, and but one argument, that of experiment Experiment has dethroned the word So while civilisation endures in any part of the world the growth of science must go on, and with it an ever-increasing control by man of his environment and of his destiny

The Services.

THE DIRECTOR-GENERAL, R N

Surg Rear-Admiral Arthur Gaskell, C B, O B E, who, as stated below, has been appointed to succeed Sir Joseph Chambers as Director-General of the Medical Department of the Navy, joined the Service in 1893, became staff surgeon in 1902 (for conspicuous professional merit at Wei-hai wei), fleet surgeon in 1906, surgeon captain in 1920, and rear-admiral in 1923 He has been director of medical studies and professor of hygiene, No 1 hospital ship, A.D M S, R N Division, R N Hospital, Simonstown, and also in temporary charge at the R N Hospital, Chatham

TEMPORARY COMMISSIONS AT HOME STATIONS IN THE R.A M C

The War Office announces vacancies in the Royal Army Medical Corps for temporary officers to be employed at home stations Candidates for these commissions must be registered medical practitioners, under 55 years of age, and they will be required to give an undertaking to serve for at least six months After that period appointments will be terminable by a month's notice on either side Accepted candidates who fulfil the necessary conditions will be considered for permanent Commissions if they so desire Pay for those who have not previously served in the Royal Army Medical Corps will be at the rate of £600 per annum, but the initial rate for those who have served for not less than 12 months as officers of the Corps will be £650 per annum In each case there will be an outfit allowance up to £40 Applications should be sent to the Under Secretary of State, The War Office, Whitehall, S W 1, from whom full particulars may be obtained

ROYAL NAVAL MEDICAL SERVICE

Surg Rear-Admiral A Gaskell, C B, O B E, has been appointed to the *President* for duty inside Admiralty, and as Director-General of the Medical Dept., vice Surg Vice-Admiral Sir Joseph Chambers, K C B, C M G

Surg-Lts —J G Currie to *Beaufort*, and E C Downer to *Flinders*

ROYAL ARMY MEDICAL CORPS

Lt-Col E P Connolly, from R A M C, to be Col, vice Col J W H Houghton, to ret pay

The undermentioned Lt-Cols, Reg Army Res of Off, to be Majs, whilst re-empld, Royal Warrant for Pay and Promotion, and relinquish the rank of Lt.-Col J L. Wood and W E C Lunn

Capts to be Majs H A. Rowell, C F Anthonisz, and S O Dolan

Temp Lt R L J Le Clezio relinquishes his commission

ROYAL AIR FORCE

Flying Offs L. C Palmer-Jones and T W Wilson to be Flight Lts

Temp Lt. W D Guyler (General List, Army Dental Surgeon) is granted a temporary commission as a Flying Officer on attachment to the R A.F He will continue to receive emoluments from Army sources

> "Thus the disease makes its progress from the Horse (as I conceive) to the nipple of the Cow, and from the Cow to the Human Subject
>
> "Morbid matter of various kinds, when absorbed into the system may produce effects in some degree similar but what renders the Cow Pox virus so extremely singular, is that the person who has been thus affected is for ever after secure from the infection of the Small Pox, neither exposure to the variolous effluvia, nor the insertion of the matter into the skin, producing this distemper"

He produced no proof that grease could cause cow-pox on the teats of a cow; or did he make any experiments, as he might easily have done to test the truth of his assertion

Jenner, after the publication of the inquiry was soon inundated by reports from medical men and veterinary surgeons of repute in the neighbourhood of persons who were attacked with small-pox after having had cow-pox He did not hesitate to get over the difficulty He published "Further Observations &c, &c," in which he states that there was a *spurious* cow-pox the use of which would account for the failures He writes —

> "Would it not be discreet for those engaged in this investigation to suspend controversy and cavil until they can ascertain with precision what *is* and what *is not* the genuine Cow Pox"

Again—

> "One of the first objects then of this pursuit, as I have observed, should be, to learn how to distinguish with accuracy between that peculiar pustule which is the *true* Cow Pox, and that which is *spurious* Until experience has determined this we view our object through a mist"

He here admits that the *genuine* and *spurious* cow-pox are indistinguishable The suggestion of *spurious* cow-pox, however served well his purpose Whenever small-pox followed cow-pox, the latter was *spurious*, and, on the other hand, if perchance small-pox did not develop that was evidence that the person was protected by the *true* cow-pox—the horse-grease cow-pox of Jenner!

We are now in a position to ask What was the "wonderful discovery" of Jenner? He did not discover cox-pox That was universally known He did not discover that cow-pox was a preventive of small-pox He knew it was not The only discovery he laid claim to was the horse-grease cow-pox And there is no such disease Indeed, he was wise enough to drop it on the advice of Woodville, who wrote him "the very name of horse-grease was like to have wrecked the whole concern"

In conclusion, let me quote from M Fabre, one of the greatest observers who ever lived —

> "An incomplete observation wrongly interpreted, sets the story going Then come the compilers who faithfully hand down the legend, the unsound fruit of the imagination and error, confirmed by repetition becomes an article of faith"

I am Sir yours faithfully

H H TAYLOR, J P F R C S

Hove, Feb 26th 1927

CONTRACEPTIVES

METHODS IN COMMON USE COMPARED

To the Editor of THE LANCET

SIR,—Having special interest and practical experience in the ordinary "birth control" methods, I should like to enlarge upon or criticise Dr Giles's comments in his address on the subject reported recently in THE LANCET Whether or no we approve, it is obvious that the whole question grows in importance and that the practice is very widespread The facts must be made clear and faced frankly

When Dr Giles says that restrictions early in married life rob marriage of much of its proper "romance" I suspect he must be thinking of the minority of comfortably-placed parents of middle and upper classes There is little "romance" among the overcrowded people of the industrial areas where I work, and this "romance" is not fostered by endless childbearing, starting in young girls on the threshold of life, who, a few months after the marriage ceremony, are in the throes of labour, with all the real freedom of youth ended ere it has scarce begun Pregnancy and parturition themselves are under most conditions, anything but romantic—they are too often the beginning of economic difficulties, home imprisonment, changed bodily appearances (if not changed bodily health) which thrust maidenhood into matronhood rudely and abruptly

Disillusionment can also, of course, follow childless unions, but surely there is a happy mean? Anyway, I do not believe the widespread use of contraceptives is always due to selfishness—may it not be equally well *an ideal?* Could we not credit people with a real desire to avoid the wastage and misery of the hordes of unwanted, useless lives that are thrust daily into this world? Is the daily prayer and hope that sexual intercourse will not result in undesired pregnancy any better than the mutually agreed effort to make certain it won't? The very fact that the question is controversial and difficult commends it to our impartial study Admitting its popularity, let us have proper teaching and regulation rather than ignorant misuse.

The *methods themselves* need a more detailed analysis

1 *Abstinence*—I quite agree with Dr Giles's remark on the impracticability of this, but he seems inconsistent when he says previously, "Let such people" (i e, those who marry but avoid pregnancy to "enjoy" their youth) "enjoy themselves and have a good time, and wait to get married, &c," and this, under modern conditions We all know what a "good time" means in these days, it entails considerable *abstinence* under constant sexual stimulus and too often ends in irregular intercourse (or its substitutes), disease and illegitimacy. So many of the sexual troubles, direct or indirect, of our young people are due to *postponement* of marriage till long after the age of fullest sexual vigour and to the *disharmony* which this produces Better, surely, a childless marriage at first than the daily unpublished tragedies of perverted and promiscuous "love" As Dr. Giles says. "It asks too much of human nature and opens the door to irregular practices and unhappiness"—and far worse

But why this common suggestion that sexual congress is a peculiar weakness, nay, crime almost of *human* nature Is it not the most natural and powerful instinct through the whole fauna and flora of the world? Under proper conditions there is nothing to be ashamed of It is this strange teaching of hypocrisy and secret, censorial attitude which does so much harm The forbidden and mysterious have always an unhealthy attraction

2 *Restriction to Safe Period*—Not only is this most unreliable, but reduces coitus to a *regular habit* or ceremony every month and ignores the all-important æsthetic and affectionate aspects, &c, as well as all consideration for the desires and moods of the female partner At the risk of being accused of "eroticism," I would emphasise the importance of *mental harmony* and mutual romanticism in an act which affects so profoundly every cell of the body and every emotion of the mind This especially applies to woman, and if there is any choice she should be the one to make it. In my opinion the method, if it can be called one, is to be condemned as useless or mentally harmful

3 (*a*) *Coitus Interruptus*—I would not only not recommend this, but condemn it wholesale, as the *worst of all* for these, among other reasons already mentioned by other authorities It is not only unnatural but, for most men impossible without unpleasant practice Even with this practice, *fear of failure and the strain of divided attention*, on both parties, have serious effects on the natural and *mutual* climax of the act It abolishes the equally *natural rest* and mutual *support* of the parts during deturgescence If successful it produces a sense of *revulsion* (if only by the misplacement of semen) in rightly sensitive women, while, even so it is quite *uncertain*, since under sexual excitement, there may be leakage of

VENTILATION IN THE HOME

To the Editor of THE LANCET.

SIR,—Public opinion in favour of reducing our output of domestic smoke has undoubtedly been quickened by the recent shortage of coal, and people generally are showing a much closer interest than heretofore in the problem of heating and ventilating the home But reforms are seldom achieved without some abuses, and one effect of the increased demand for various smokeless appliances as an alternative to the coal grate has been the marketing of many kinds of cheap heaters which do not fulfil the most elementary requirements of domestic hygiene I refer particularly to so-called portable heaters—gas, oil, and electric—which either discharge the products of combustion into the air of the room or, because they are unconnected with a chimney or flue outlet, fail to induce an adequate influx of fresh air, which is essential to the proper ventilation of a room

Medical men naturally have a keen appreciation of the importance of ventilation in the home, but perhaps it is not fully realised that certain types of flueless heaters—especially gas-heaters—which may be safe enough in corridors, halls, churches, large rooms, and other places where there is a constant and free circulation of air, are a positive menace to health when used in the bedrooms or living rooms of the average-sized dwelling-house While, therefore, as one whose work is largely devoted to mitigating the smoke evil, I am not inclined sweepingly to condemn every form of heater which is not connected with a chimney or a flue of adequate size, I would lay it down as a general principle that flueless gas stoves for heating living rooms should be looked on with suspicion The size of the apartment and the amount of free ventilation are determining factors in deciding on their suitability

No fuel-using appliance consumes its own products and so-called "condensing" stoves condense little else but water When coal-gas is completely burned, the products of combustion consist chiefly of carbon dioxide and water vapour, these escape directly into the surrounding atmosphere, unless led into a suitable chimney or flue If a flueless heater is correctly designed, and no mistake in working it or leakage occurs, the products of combustion are comparatively harmless An ordinary seven radiant gas-fire connected with a chimney burns approximately 30 cubic feet of gas per hour and produces as much carbon dioxide as about 15 men With a flueless fire it would be necessary to burn only about 20 cubic feet per hour, but then all the products would enter the room, and, so far as carbon dioxide is concerned, the effect would be equivalent to about 10 men Unfortunately, this is not the whole story. Probably the greatest danger is the production of CO when the gas-fire is not correctly designed, and the flames, owing to proximity to cool surfaces, are not allowed to complete their combustion to CO_2. The same result might follow in the case of a flueless heater of correct design if the ventilation is not sufficient to prevent the accumulation of CO_2 and provide oxygen to ensure complete combustion

In rooms heated by flueless gas-fires and not adequately ventilated, the humidity of the air rapidly increases while the oxygen is depleted, and both of these have injurious effects This ventilation difficulty is a very real one, as people are tempted to cut down the supply of fresh air to a minimum in order to economise heat, which reacts unfavourably to the use of flueless heating of any kind There is again the danger of leakage from the flexible tubes with which flueless gas-fires are often fitted The points I would stress are those amplified by Sir Napier Shaw and myself in our book "The Smoke Problem of Great Cities" —

1 Gas-fires should have a free entrance for air to the chimney, independent of the flue drawing the products of combustion from the fire This is provided for in the modern "ventilating" gas-fires by an air entrance under the canopy

2 The heating and ventilating of houses should be inseparable, and any method of heating which does not itself produce a ventilating effect should be looked on with suspicion

The foregoing remarks will, I trust, be of some assistance to members of a profession, which is necessarily closely interested in the question of ventilation of the home and has done so much to rouse public opinion to a realisation of the baneful effects on health of smoke and fog

I am, Sir, yours faithfully,

JENNER'S REAL CLAIM

To the Editor of THE LANCET

SIR,—In Dr James Bennett's address entitled Pending Changes in the Administration of Vaccination, in THE LANCET of Feb 5th, he refers to the "wonderful discovery of Jenner" The "discovery" was made so long ago that probably very few men at the present time are aware of what Jenner really claimed to have discovered

Cow-pox is a vesicular disease affecting the cow's udder in milk It is contagious, not infectious, and bears only the remotest resemblance to small-pox In the eighteenth century it was prevalent over the whole of the United Kingdom and elsewhere There was a myth existing in the West Country, purely local, as so many superstitions are, that milkers who had contracted cow-pox were rendered immune to small-pox Jenner, being a general practitioner in Gloucestershire, was quite familiar with this myth He frequently broached the subject to his medical colleagues at his club (the Convivio-Medical at Alveston), and according to Baron, made himself somewhat of a bore, as most of them had frequently seen cases of small-pox following cow-pox, and knew it to be only a superstition, and told him so Jenner knew that cow-pox, as generally met with, was not a prophylactic against small-pox

Let us now see what he himself always claimed to have discovered In 1898 he published an essay (which the Royal Society had declined to publish) entitled "An Inquiry into the Causes and Effects of Variolæ Vaccinæ, a disease discovered in some of the Western counties of England, particularly Gloucestershire, and known by the name of the Cow Pox" It is important here to notice, first the use of the word "discovered," and secondly, that he states that cow-pox was small-pox of the cow Not once in the body of the inquiry does he attempt to justify such an outrageous statement

I proceed to quote from the inquiry —

> "There is a disease to which the Horse, from his state of domestication, is frequently subject The Farriers have termed it *the grease* It is an inflammation and swelling in the heel, from which issues matter possessing properties of a very peculiar kind, which seems capable of generating a disease in the Human Body (after it has undergone the modification I shall presently speak of), which bears so strong a resemblance to the Small Pox, that I think it highly probable it may be the source of that disease

> "In this Dairy Country a great number of Cows are kept, and the office of milking is performed indiscriminately by Men and Maid Servants One of the former having been appointed to apply dressings to the heels of a Horse affected with *the grease*, and not paying due attention to cleanliness, incautiously bears his part in milking the Cows, and some particles of the infectious matter adhering to his fingers When this is the case, it commonly happens that a disease is communicated to the Cows, and from the Cows to the Dairy Maids, which spreads through the farm until most of the cattle and domestics feel its unpleasant consequences This disease has obtained the name of the *Cow Pox*"

Of course, this is stultilogical Grease is seborrhœa of the horse's heels He then gives a fairly accurate description of the natural cow-pox affecting the cows and milkers if he had never seen the optician's winking-eye sign It would be a simple matter to compile a formidable list of such errors from our case-books, yet we would never expect to find any *real damage* done to the eyes Mr Caddy, by almost apologising for a non-existent danger of unqualified practice, has concealed the real danger—for discomfort and loss of efficiency is a real danger to the community

I would agree with Mr Caddy's suggestion that the ophthalmic panel should consist of men practising ophthalmic surgery only Human nature being what it is, we all agree that it opens the door to abuses, to give doctors the opportunity of referring cases for ophthalmic benefit to a member of their own firm One has to admit that, under such circumstances, patients may be referred unnecessarily. Similarly, a man who goes into an optician's shop will frequently have considerable pressure put on him to buy a pair of glasses whether he needs them or not

Mr Caddy's penultimate paragraph prompts me to apply to Murray's New English Dictionary, where I find—Optician a maker of, or dealer in optical instruments Oculist one versed in the knowledge or treatment of the eyes

One might therefore define an "unnecessary" interview with an ophthalmic surgeon as an interview with him by a person who had no trouble with his eyes If a person has any trouble with his eyes, the man to whom he ought to go is the oculist, and the interview is then not "unnecessary"

After all, to whom does the wealthy man or the educated man go if he is in trouble with his eyes—he goes to an oculist and if glasses are required he has them made by an optician To whom does the poor man go—to perhaps the same oculist at a hospital, where his prescription is made up by a dispensing optician This is the ideal way to go about it, and there is no unnecessary waste of time—the optician takes just as long as, or even longer, than the oculist to test the vision The people who support the sight-testing optician are getting only second-best, inexpert and not disinterested advice, and one is sorry to see a surgeon of repute countenancing such a system —I am, Sir, yours faithfully,

ALEX G LUMSDEN

Wimpole street, W, Feb 28th, 1927.

AN APPEAL FOR SUPPORT

To the Editor of THE LANCET

SIR,—I beg that you will kindly permit me to make an appeal in your columns for a monetary grant in aid of my researches, as I have failed to get one from different sources appealed to, and my work is greatly hampered for lack of funds

We have found here that toxins occur in the blood of animals treated by liver grafting and have published a note on that in the *Journal of Physiology*, December, 1926 We can now state that similar toxins result from the action of certain drugs and probably from certain methods of procedure to be published very soon These facts seem to have an important bearing on Rontgen sickness, on blood transfusion, and on many biological problems which interest the medical profession

I am, Sir yours faithfully,

FEDERATION OF THE HEALTH RESORTS OF FRANCE —An information bureau has been established in London by this Federation, whose full title is the "Union des Etablissements Thermaux et Stations Climatiques de France" New offices have been taken at 19A, Tavistock-square and Mme Juppé-Blaise has been appointed manager Full information will be available at the bureau concerning the spas and health resorts of France, and arrangements can be made through it for travelling facilities and for hotel accommodation The new organisation has been planned to give full replies to all inquiries concerning residence in France

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

Dr Haden Guest

DR HADEN GUEST, who has been a member of the Labour Party in the House of Commons, since 1923, has resigned from the party, owing to his disapproval of the official attitude of the Opposition toward the Government's policy in China It is believed that he will at once apply for the Chiltern Hundreds

HOUSE OF LORDS

WEDNESDAY, FEB 23RD

LEAD POISONING—SIR T LEGGE'S RESIGNATION

Lord ARNOLD called attention to the resignation of Sir Thomas Legge from the position of senior Medical Inspector of Factories and to the Draft Regulations made under the Lead Paint (Protection Against Poisoning) Act, and moved for papers There was no doubt that the use of lead paint had been the cause of serious injury to the health of many workers For some years there had been several hundreds of cases of plumbism annually, and probably about 40 deaths per annum occurred owing to lead poisoning The consequences of this disease, which were always bad, were sometimes extremely grave, because even when not fatal some of the cases led to paralysis and some to blindness It was with a view to stopping the suffering caused by this terrible disease that under the auspices of the International Labour Office of the League of Nations a Draft Convention was agreed to at Geneva in 1921 by the representatives of 30 countries, including Great Britain, and under that Convention the use of lead paint for interior work was to be prohibited after 1927 It was, to use no stronger language, extremely regrettable that the Conservative Party in the Act passed last year went back on this Convention and instead of prohibiting the use of lead paint for interior work merely enacted that its use should be regulated. The Act, when passing through Parliament, was strongly opposed by the Opposition on the ground that the Bill was a breach of what was agreed to by this country at Geneva in 1921 That accusation had been enormously strengthened owing to the resignation of Sir Thomas Legge, who had resigned his position under the Home Office solely on account of the action of His Majesty's Government in this matter Sir Thomas Legge, as one of the delegates of the British Government at Geneva in 1921, voted there for the Draft Convention, and he was not willing to be a party to going back on what he then did

Their lordships would be aware that it was a very unusual circumstance for a civil servant to resign on a point of disagreement with the Government, and the fact that Sir Thomas Legge had felt it his duty to do so emphasised in the strongest possible way the Government's breach of honour in this matter Sir Thomas Legge, as a civil servant, could, of course, have claimed that the responsibility was that of the Government, but so keenly did he feel that what had been done was wrong and that it would mean suffering and death which would otherwise be avoided to many men that he was not willing any longer to remain in the service of the Home Office Nothing whatever had happened since 1921 to warrant the Government going back upon the decision then taken, and the position was rendered all the worse because the proposal at Geneva which led to the Draft Convention being unanimously agreed to was actually made by Great Britain It was the white lead manufacturers of this country which formed the vested interest which caused the Conservative Government to break faith and to pass the measure of last year Sir Montague Barton knew that the Convention was not wholly acceptable to the white paint manufacturers when he voted for the Convention at Geneva The harm done by lead paint in interior work mainly arose from rubbing down the old paint in order to prepare the surface for the new paint In this process particles of dust were spread about and got into the worker's system, chiefly through the lungs, and caused poisoning The same thing did not occur to anything like the same extent in external painting, because in that work very much less rubbing down had to be done, and the work being done in the open air the particles of dust were blown away Waterproof sandpaper was supposed to meet the difficulty but in practice the case for waterproof sandpaper broke down So many things had to be done in connexion with its use that in practice they would hardly ever be done Moreover, the sale of waterproof sandpaper among house painters had so far made very little progress The vital point in all this matter, and one which hitherto the Government had entirely failed to apprehend, was the injurious effect of the vesicular fluid containing spermatozoa Further, violent withdrawal is often *painful* to the woman and might even favour prolapse Above all, with its serious consequences, there is the *curtailment of the act* and sudden break in the psychic chain for the female partner, which leaves every part in a state of unresolved, tense excitement

3 (*b*) The *condom* is, I agree, convenient, fairly safe, and available under most conditions—even by the most ignorant—but it has many objections not mentioned by Dr Giles It is, if really reliable, very *expensive*. Even the best makes get torn under the common difficulties of some sexual relationships Unless previously lubricated, rubber is very apt to obstruct penetration; this causes some pain and difficulty Artificial lubrication, which is seldom necessary under normal conditions of free secretion, is æsthetically objectionable, and the same may be said of putting on a sheath just before coitus (obviously erection is necessary). At any other great emotional moment, such an irrelevant interruption would be devastating Moreover, the wide use and recommendation of this method may over-popularise the condom to the detriment of morals, since it is the only one available for promiscuous and unpremeditated intercourse which dispels the two chief inhibitory fears of disease and conception

4 *Rubber Check Pessaries in Vagina* —This method, in my experience, is free from nearly all the objections in connexion with other methods and equally, if not more, certain in action. Above all, the pessary can be *fitted, unobtrusively, long before the act and forgotten*, so that the natural spontaneity and "romance" (for want of a better word) of the act is in no way interfered with The complicated psychic processes can run their course smoothly and harmlessly. No method is as yet ideal, and I will concede the *difficulty of fitting* for an ignorant or dirty mother But even this is exaggerated and most women can be instructed in this as they can be instructed to clean their teeth or do their hair. The dangers of sepsis and improper application are those inseparable from all misuse and dirty habits. The pessaries are *inexpensive* and last a long time with ordinary care Safety, *almost* amounting to certainty, can be guaranteed if they are used in conjunction with quinine pessaries

5 (*a*) *Soluble Quinine Pessaries* —The apparent excellence of these is qualified by two or three objections they are *expensive* and just as great—in fact a greater—"source of revenue to those who sell them," as Dr Giles would have us believe about check pessaries They always make *greasy stains* on bedding or clothes; then the smell of cocoa-butter is distasteful to many, and the part played by the olfactory sense in sex is too often ignored; they entail objectionable fumbling just before coitus Further, they are by no means certain in action if used alone, since some of the spermatozoa may be injected straight on to the os externum, while the melted quinine-butter will lie in the fornices out of the way. The power of traces of quinine (manufacturers are naturally sparing with an expensive drug) to penetrate a mucous mass is doubtful

5 (*b*) *Douching* is to be *condemned* not only on account of the liability to the production of chill and shock. For the ordinary self-administered douche seldom reaches the fornices, and the effect of washing out the natural flora and bactericidal secretions of the vagina can be nothing but harmful The syringe itself is clumsy, awkward to pack, and difficult to keep clean

From the "romantic" point of view, again, this method is ruinous, both to the husband conscious of the sordid performance going on nearby and to the wife, cold and disturbed, in an anti-climax of feeling The natural sleep and sense of comfort which should follow complete coitus is rudely interrupted The sublime too often descends to the ridiculous through neglect of detail

THE ÆTIOLOGY OF CARDIOSPASM.

To the Editor of THE LANCET.

SIR,—Mr John Morley in his instructive paper on cardiospasm in THE LANCET of Feb. 26th justly implies that the generally accepted explanation of the ætiology of cardiospasm—viz, an incoordination of the neuromuscular mechanism of deglutition—is no explanation at all.

It is commonplace knowledge that the anal sphincter can be demonstrated in full and sustained contracture when the neighbouring mucosa is the seat of a fissure It seems to me to be probable that the physiological sphincter of the cardia may also be thrown into a state of irritation when its overlying mucosa is abraded, or, what is more probable, when the neighbouring mucous membrane is the seat of a (small) chronic ulcer This simile is heightened by the fact that excellent results are obtained by digital dilatation of the respective sphincters in each of these conditions

To substantiate this claim in the case of cardiospasm, we have only to refer to Mr. Walton's paper in the *British Journal of Surgery* of April, 1925

I am, Sir, yours faithfully,
Birmingham, Feb. 25th, 1927. HAMILTON BAILEY.

OPHTHALMIC BENEFIT.

To the Editor of THE LANCET

SIR,—I venture to say that few medical men, and still fewer ophthalmic surgeons will have read the extraordinary letter from Mr Adrian Caddy which was published in your last week's issue without considerable astonishment One finds in it a lofty detachment from the affairs of his brother practitioners, but one looks in vain for any sign of *esprit de corps* or for a scrap of evidence in support of his assertions. He "gathers" this, he "would go so far as to say" *that this is* "*probably*" so, *and that* "might be the case"

These are mere words for words' sake, they provide no material for thought Mr Caddy asserts that the vast majority of eye cases require glasses only There may be two opinions about that, but perhaps Mr Caddy will agree if I suggest that all eye cases who go to sight-testing opticians will be sold a pair of glasses, whether they are in that vast majority or in the minority who do not require glasses

What grounds has Mr Caddy for stating that opticians in 80 per cent of cases prescribe correct glasses? Has he spent a week or two in an optician's shop, checking the optician's treatment by personal examination of his clients? If he has not, then I think it is fair to state that his figures are pure assumption and therefore valueless

Mr Caddy is at pains to explain that he thinks that little *real damage* can be done to the eyes by unrestricted prescribing by opticians No ophthalmic surgeon believes that any actual damage can be *done* to the eyes in this way If he ever says so, it will only be in warning patients against *sight-testing* opticians, and it then becomes simply a justifiable hyperbole Mr Caddy cannot be ignorant of the reason why we warn our patients against sight-testing opticians Leaving aside *real damage* to the eyes, there is such a thing as morbidity such a thing as interference with the exercise of the functions of the eyes May I illustrate what I mean, just before reading Mr Caddy's letter *I saw a tailor* who had compound hypermetropic astigmatism The glasses he required were as *follows* —

Rt +0 5 sph +3 5 cyl 70°; Lt +0 5 sph +3 0 cyl 110°

For 18 months he had been wearing lenses suitable for the correction of compound myopic astigmatism, sold to him by a sight-testing optician That man would have been saved months of pain and discomfort, and would have been more efficient and have earned a good deal more money at his trade dangerous, and that unfortunate idea of detention had far too long run throughout the whole system. There was a popular misconception, which existed very largely to-day, that the majority of lunatics were violent and dangerous, that they had homicidal or suicidal tendencies, and that if they were left at large they would immediately run amok. That was singularly untrue to-day. It was absolutely necessary if they were to deal with this serious question in the light of modern medical knowledge and treatment that they should get out of their minds the idea that lunatics as a class were violent and dangerous people for whom the primary treatment was detention. They should be treated for their mental ailment on medical lines exactly as other people were treated for their bodily ailments. There was the important difference, of course, that those of sound mind were able to coöperate as a general rule with those who were trying to benefit them, but even that was not always true in cases of delirium. The difficulty in regard to persons of unsound mind was that the vast majority were satisfied that they required no treatment at all and that any attempt to treat them or confine them was an outrage. It was very important that they should not only remove from the minds of the public the impression of which he had spoken, but also that they should remove this other impression from the minds of the patients and in the modern method of treatment he thought a good deal had been accomplished in that direction.

It was about 25 years since he was actively occupied in inspecting asylums and since that time there had been a most marvellous development. The old apparatus of locks, bars, and prison-like surroundings had very largely gone and the amount of freedom which existed in the modern asylum would have been unthinkable a quarter of a century ago. There was one institution—true, it was a private institution, and not rate-aided—where something like 40 *per cent*—*certain 30 per cent*—of the patients were allowed to leave the institution on parole and go freely into the town, deal with the shops and associate with the townspeople. It was true of a great many institutions that certainly less than 50 per cent. of the patients were kept actually under lock and key. An important class of mental patients which had helped to raise misapprehension in the public mind were the paranoiacs, persons with a fixed delusion from which they could not escape. In all other respects such people might be sane, logical, and reasonable human beings. Here came in a very difficult question—namely, the definition of insanity. He would not attempt himself, and he thought that none of those who sat on the Commission, in spite of the assistance medical and other which was given them, would feel competent to write a treatise on the definition of insanity. The standard that the law laid down, however, was a more possible one to arrive at. The legal standard was one of conduct. Suppose a paranoiac had a delusion that the earth was flat and nothing could cure him from that delusion, that delusion was perfectly harmless, and there was no reason why he should be confined. Another delusion, by no means infrequent in women, was that some distinguished public man was their lover or their husband and that they were being forcibly and wrongfully kept away from him by the intrigues of other people. So long as that delusion did not lead to any action it was not for the law to interfere, not even though perhaps the victim was pursued with letters. But if it led to the action of camping on his doorstep, ringing his front door bell, hampering him in his public work, then the interests of the sane had to prevail and it became necessary that the person should be in some way restrained. It was because of this class of paranoiacs that the cry was sometimes raised that lunatics were wrongfully detained. No person seeing lunatics of this class detained in an asylum would be able to ascertain that they were in any way affected. They would think, and possibly in some cases they would report, that a perfectly sane man was being wrongfully detained. The Royal Commission made the most special inquiries into all allegations of wrongful detention and they were not able to trace in the whole of the asylums of this country a single case in which they could say that a man was wrongfully detained. That was stated in the Report, and it ought to reassure the public, but he was afraid that the kind of public that raised these allegations against the treatment of lunatics and the conduct of asylums was sometimes not susceptible to the argument of facts.

There was also the question of wrongful certification, a process which had attracted great attention. Certification was hedged round with precautions that ought to operate successfully, and again he was glad to say that they did not come across any case in which they could say that a man had been wrongfully certified. It would not be honest to say that there were not cases in which a business which ought to be regarded as a very serious and responsible one was sometimes a little too much of a routine, but there was no case of wrongful certification. There were a great many cases in which there was no sort of doubt about certification in view of the doctor's report. But there always must be border-line cases where the conduct had been abnormal, and where on the doctor's advice the certifying magistrate must be told that it was likely that the conduct would remain abnormal or become more abnormal. On the contrary, the conduct of the patient might become better and it might be said that the patient had been certified unnecessarily. There was a curious thing about certification, and about the early stages of this disease, that as a general rule the most violent, the most obstreperous and most obviously lunatic of the persons to be certified were generally the persons soonest to be cured and discharged. These were the people of whom doctors had hope. The well-behaved lunatic with one obsession was a man in whose case hope was generally absent, and in such instances the fixed delusion was almost always associated with an idea of persecution. In such a case, the idea of persecution grew until the patient developed a desire not merely to break plate-glass windows, but a homicidal tendency towards the person he believed to be his persecutor, and it therefore became impossible ever to let him loose on society. In view of the large number of patients whom it was possible to discharge within a few weeks, and very often within a few days of certification, the Commission were moved to consider whether some provisional treatment could not be found by which these cases could be dealt with without actual certification. Besides the stigma attaching to a person who has been certified as a madman, there was also the stigma of the Poor-law. As the law now stood, practically every person who was dealt with in a rate-aided institution—and that comprised almost the entire body of certified lunatics in the country—was technically a pauper lunatic. In most cases also certification proceeded through the workhouse, or if not through the workhouse, at least in connexion with the relieving officer, who was a Poor-law official. Their lordships would see the difficulties that had to be faced in connexion with provisional treatment. If there was to be an incomplete and provisional stage, was it to be on the doctor's certificate alone, or, as in the present case, on a doctor's certificate backed up by the order of the justices? The power of restraint was absolutely necessary, but a considerable portion of the recommendations of the Commission was devoted to a system of provisional treatment and a sort of quasi-certification, which would not be called certification, extending say for six months. All the evidence showed that the majority of those certified would be discharged before the expiration of the period, and would be able to say that they had never been certified lunatics. That was a matter to which the Commission attached a good deal of importance.

There was also the very important question of classification at the early stages. It was obviously desirable that earlier classification of persons suffering from mental disorder should take place. But this was, to a large extent, a question of the amount of money they were going to spend. Closer classification meant more medical officers, more attendants, smaller wards, and in many cases new buildings. All that the Commission had been able to do was to lay the considerations before Parliament in their report, and to point out that the adoption of those recommendations would give a return, not only in actual dividends of the smaller number of lunatics to be maintained at the public expense, but in the quicker return to health of the citizens of the country. He thought that it was undoubtedly the case that in most of the rate-aided asylums at this moment it would be better to have a definite increase in the number of medical officers and a definite increase in the number of attendants. Wards were too large and individual attention was too difficult. But here he did not wish their lordships to be misled. If they took the average asylum, say for 1000 cases, unfortunately there was a very large percentage of that population for which medical treatment was no use. There was the hopeless cases, the advanced cases of general paralysis of the insane, the ordinary senile dements, and so on. That class did not want an increase in medical attendants. There were other classes in perfectly good physical health, such as paranoiacs, in which after a certain stage they ceased to have very much hope. But at the same time constant watchfulness and care and constant individual observation of those who they had any hope of preparing for discharge was the best and only way of getting maximum discharges from asylums. It was very early brought home to the Commission that the chief pride of the superintendent of an asylum was not the number of inmates that he managed to keep, but the number that he managed to set free; that was what every doctor aimed at. The advances which had been made in the last 25 years had not been due to the Legislature or even to the excellent work of the county councils who controlled these institutions, but primarily to the initiative of the medical men themselves who were constantly seeking to deal as best they could with these unfortunate cases. There was no drug that would cure it, nor any specific treatment; they could only put the patient in the best position to fight the disease himself. He put this point to one of the most distinguished doctors who came before the Commission, and he admitted that that was practically the position.

action of Great Britain on future international meetings at Geneva for the purpose of raising labour conditions Great Britain who had been in the forefront of civilised countries in efforts for raising those conditions, bid fair to lose her influence abroad in these matters and to become an obstacle instead of a help to progress The Home Secretary had used words in the House of Commons in connexion with this matter which he (Lord Arnold) thought ought not to have been used, because they gave a wrong impression He began by saying that Sir Thomas Legge, having reached the pensionable age, asked to be allowed to retire As a matter of fact, the pension age had nothing to do with the matter Even if Sir Thomas had reached the retiring age—which he had not—there was no reason to suppose in view of his experience that his term of service would not have been somewhat extended, indeed, the Home Secretary when pressed admitted that that was so The Home Secretary also said that Sir Thomas Legge gave as the reason for his resignation the fact that he did not wish to be concerned in the administration of the Lead Paint Act That statement was not really in accordance with what occurred The main reason Sir Thomas gave was that he could not recede from the position he had taken up at Geneva In the letter which was sent out by the Home Office dated Dec 31st, 1926, explanatory of the Draft Regulations under the Lead Paint Act it was stated that the terms of the Regulations had been discussed at a series of conferences between the Home Office and various bodies, including among others the National Operative Painters' Society, and that complete agreement was arrived at That statement was grossly misleading The fact was that the Regulations referred to were nearly all drafted to apply to external painting and were drafted as long ago as 1922 They were agreed to then by the various bodies named in the letter when it was understood that the Geneva Convention was going to be ratified and that so far as interior work was concerned the use of lead paint would be prohibited The Act did not receive the Royal Assent until Dec 15th, and this circular was sent out on Dec 31st No conferences were held between those two dates so far as he knew In the second place the Home Office letter did not in the least make it plain that the Regulations were nearly all drafted for external painting Certain additional Regulations were issued about which, as far as he knew, there had never been any discussion or conference The National Operative Painters' Society had made various objections to the Regulations and had pressed for various amendments The Regulations would be of very little use in stopping lead poisoning In France lead paint was hardly used at all now, zinc paints were used instead Zinc could be used for interior work because that work was not affected by climate There was no reason to suppose that other substitutes as well as zinc could not be found for lead paint—substitutes not harmful to health He urged most strongly that the Government should make it clear that they would before long introduce legislation prohibiting the use of lead paint for interior work If things could work out in that way then the resignation of Sir Thomas Legge, though the sacrifice had been great, would not have been in vain

Viscount **Burnham** said he much regretted that Lord Arnold had thought fit to make a speech of such vitriolic violence on one of the most vexed and difficult problems of industrial policy in international affairs The only reason why he (Lord Burnham) interposed in the debate was, because he presided over the International Labour Conference of 1921 at Geneva, and as chairman of the drafting committee he was, to some extent, responsible for the Draft Convention on Lead Paint Personally he regretted that His Majesty's Government had not been able to recommend Parliament to ratify that convention On the other hand listening to the somewhat uninformed arguments that had been addressed to the House their lordships might be led to imagine that this was a question of breach of faith without regard to the health and welfare of the workers in the trade which used white lead in interior painting or to the general opinion of the civilised world The facts were very different The Conference sat for some six weeks in 1921, and of all the questions submitted to it there was none which provoked so much controversy as the use of white lead in painting It was not, as Lord Arnold led their lordships to believe, a matter of humanity against callousness in regard to human health and welfare, on the contrary, it was a great struggle of trade interests in which the arguments were very powerful on both sides, and as the result of which a compromise was adopted entirely owing to the persuasiveness and the ability of Sir Thomas Legge It was a fight between the lead-producing and lead-using countries, and the zinc-producing and zinc-using countries The Commonwealth of Australia, for instance, was unanimously against any such Convention Germany ranged itself on the same side as Australia, while France and Belgium being zinc-producing and zinc-using countries saw an advantage, not only from the hygienic but also from the commercial point of view in the adoption of such a Convention Three committees were appointed to consider the matter—a commercial, a scientific, and a hygienic committee They had experts of the greatest authority sitting on them He recollected that there was one who was paid £5,000 for coming to Geneva, but he was not paid in the least from any reason of public health, but because the vital interests of a great many countries, which were members of the League of Nations, were concerned, and especially those of Australia where lead constituted one-third of the whole mineral production It was almost certain, at last, that no agreement could be reached, and he broke all the rules of procedure in order to allow Sir Thomas Legge to move, almost as a desperate hope, the resolution that was finally embodied in the Draft Convention which had never been brought to the notice of Parliament On the other hand, many of those who favoured the Convention believe that half measures, though not wholly effective, might do a great deal to stop the evil of which complaint was made In 1921 the number of deaths arising from lead poisoning in the whole of the countries represented amounted to 400—a very serious, but not an enormous figure They thought therefore that it was possible that in six years such scientific discoveries and such applications of those discoveries might be made as would not put this country and other countries using lead at a disadvantage compared with the zinc countries The building trades were altogether opposed to any such Draft Convention It was only when a Draft Convention had been ratified by a national parliament of any country that was a party to the League of Nations, that it became a matter of honourable obligation There was therefore no question of dishonour in the decision of the Government not to ratify the Convention In any case, to make partizan capital out of the resignation of Sir Thomas Legge was a very monstrous abuse Nobody who knew him and had seen anything of his work, over a long period of years, could feel anything but the highest respect for him, and no doubt he was heart and soul in favour of this Convention It was his work, to a large extent. Had he (Lord Burnham) had any say in the matter, either at Geneva or at home, he would have been in favour of ratifying the Convention On the other hand if it was only postponed for a little time for further experiment and for the concurrence and co-operation of the other nations which were involved, he could not think that much harm had been done

Viscount **Haldane** said that he thought that the attitude of His Majesty's Government towards this question was a most dubious one, and that Lord Arnold had been well advised in bringing it before their lordships that day

Lord **Desborough**, replying on behalf of the Government to Lord Arnold's motion, said he would like to join with those who had already spoken in expressing the appreciation of the Home Office, of employers of labour, and of employees, of the inestimable services rendered by Sir Thomas Legge over a very long period The Home Office heard with very great regret that he considered it necessary to resign on account of a difference of opinion as to the proper method of dealing with this very important question of lead poisoning There was no doubt that he and the Government had a very serious difference on that point, but his resignation in any case could not have been very long postponed It was none the less to be regretted, for if all distinguished civil servants thought it necessary to resign because they happened to disagree with the head of a Department or the head of the Government the civil service on which the good government of this country so largely depended would soon find itself in the slough of despond In these conventions nothing whatever was signed by the delegates, therefore, there was no question of going back on any point of honour They had not got to the point when they were governed by Geneva or even by Moscow The Government, since the passing of the Act of last year had had a great many conferences with all those interested in order to draw up the best possible regulations They were very carefully going into the question of the protection of people who used lead paint by, for instance, prohibiting the use of any lead paint in the form of spray and by prohibiting dry rubbing down and scraping Those Regulations were in hand and he thought they would be shortly issued He hoped that those who wished to put a stop to this admitted evil of lead poisoning would give every assistance to the Government in order that the greatest security might be given to those who engaged in this admittedly dangerous occupation

Lord **Arnold**, who said that no attempt had been made to reply to the contentions he had advanced, withdrew his motion

THURSDAY, FEB 24TH

LUNACY AND MENTAL DISORDER

Earl **Russell** called attention to the report of the Royal Commission on Lunacy and Mental Disorder and asked whether it was proposed to introduce legislation on the subject The primary consideration of the public in the treatment of those who had diseased minds was not cure but detention, the protection of society from people who were dangerous and that unfortunate idea of detention had far too long run throughout the whole system. There was a popular misconception, which existed very largely to-day, that the majority of lunatics were violent and dangerous that they had homicidal or suicidal tendencies, and that if they were left at large they would immediately run amok. That was singularly untrue to-day. It was absolutely necessary if they were to deal with this serious question in the light of modern medical knowledge and treatment that they should get out of their minds the idea that lunatics as a class were violent and dangerous people for whom the primary treatment was detention They should be treated for their mental ailment on medical lines exactly as other people were treated for their bodily ailments. There was the important difference of course, that those of sound mind were able to coöperate as a general rule with those who were trying to benefit them: but even that was not always true in cases of delirium The difficulty in regard to persons of unsound mind was that the vast majority were satisfied that they required no treatment at all and that any attempt to treat them or confine them was an outrage. It was very important that they should not only remove from the minds of the public the impression of which he had spoken, but also that they should remove this other impression from the minds of the patients and in the modern method of treatment he thought a good deal had been accomplished in that direction.

It was about 25 years since he was actively occupied in inspecting asylums and since that time there had been a most marvellous development. The old apparatus of locks, bars, and prison-like surroundings had very largely gone and the amount of freedom which existed in the modern asylum would have been unthinkable a quarter of a century ago There was one institution—true, it was a private institution and not rate-aided—where something like 40 per cent.—certain 30 per cent.—of the patients were allowed to leave the institution on parole and go freely into the town deal with the shops and associate with the townspeople. It was true of a great many institutions that certainly less than 50 per cent. of the patients were kept actually under lock and key. An important class of mental patients which had helped to raise misapprehension in the public mind were the paranoiacs persons with a fixed delusion from which they could not escape. In all other respects such people might be sane, logical and reasonable human beings. Here came in a very difficult question—namely the definition of insanity He would not attempt himself and he thought that none of those who sat on the Commission, in spite of the assistance medical and other which was given them would feel competent to write a treatise on the definition of insanity. The standard that the law laid down however was a more possible one to arrive at. The legal standard was one of conduct. Suppose a paranoiac had a delusion that the earth was flat and nothing could cure him from that delusion, that delusion was perfectly harmless and there was no reason why he should be confined. Another delusion by no means infrequent in women, was that some distinguished public man was their lover or their husband and that they were being forcibly and wrongfully kept away from him by the intrigues of other people. So long as that delusion did not lead to any action it was not for the law to interfere, not even though perhaps the victim was pursued with letters. But if it led to the action of camping on his doorstep, ringing his front door bell hampering him in his public work, then the interests of the sane had to prevail and it became necessary that the person should be in some way restrained. It was because of this class of paranoiacs that the cry was sometimes raised that lunatics were wrongfully detained. No person seeing lunatics of this class detained in an asylum would be able to ascertain that they were in any way affected. They would think, and possibly in some cases they would report that a perfectly sane man was being wrongfully detained. The Royal Commission made the most special inquiries into all allegations of wrongful detention and they were not able to trace in the whole of the asylums of this country a single case in which they could say that a man was wrongfully detained. That was stated in the Report, and it ought to reassure the public but he was afraid that the kind of public that raised these allegations against the treatment of lunatics and the conduct of asylums was sometimes not susceptible to the argument of facts

There was also the question of wrongful certification a process which had attracted great attention. Certification was hedged round with precautions that ought to operate successfully and again he was glad to say that they did not come across any case in which they could say that a man had been wrongfully certified. It would not be honest to say that there were not cases in which a business which ought to be regarded as a very serious and responsible one was sometimes a little too much of a routine; but there was no case of wrongful certification. There were a great many cases in which there was no sort of doubt about certification in view of the doctor's report. But there always must be border-line cases where the conduct had been abnormal, and where on the doctor's advice the certifying magistrate must be told that it was likely that the conduct would remain abnormal or become more abnormal. On the contrary, the conduct of the patient might become better and it might be said that the patient had been certified unnecessarily. There was a curious thing about certification and about the early stages of this disease that as a general rule the most violent, the most obstreperous and most obviously lunatic of the persons to be certified were generally the persons soonest to be cured and discharged. These were the people of whom doctors had hope. The well-behaved lunatic with one obsession was a man in whose case hope was generally absent and in such instances the fixed delusion was almost always associated with an idea of persecution. In such a case, the idea of persecution grew until the patient developed a desire not merely to break plate-glass windows but a homicidal tendency towards the person he believed to be his persecutor and it therefore became impossible ever to let him loose on society In view of the large number of patients whom it was possible to discharge within a few weeks, and very often within a few days of certification the Commission were moved to consider whether some provisional treatment could not be found by which these cases could be dealt with without actual certification. Besides the stigma attaching to a person who has been certified as a madman, there was also the stigma of the Poor-law. As the law now stood practically every person who was dealt with in a rate-aided institution—and that comprised almost the entire body of certified lunatics in the country—was technically a pauper lunatic. In most cases also certification proceeded through the workhouse, or if not through the workhouse, at least in connection with the relieving officer, who was a Poor-law official. Their lordships would see the difficulties that had to be faced in connection with provisional treatment. If there was to be an incomplete and provisional stage was it to be on the doctor's certificate alone, or, as in the present case, on a doctor's certificate backed up by the order of the justices? The power of restraint was absolutely necessary, but a considerable portion of the recommendations of the Commission was devoted to a system of provisional treatment and a sort of quasi-certification, which would not be called certification extending say for six months. All the evidence showed that the majority of those certified would be discharged before the expiration of the period, and would be able to say that they had never been certified lunatics. That was a matter to which the Commission attached a good deal of importance.

There was also the very important question of classification at the early stages. It was obviously desirable that earlier classification of persons suffering from mental disorder should take place. But this was to a large extent, a question of the amount of money they were going to spend. Closer classification meant more medical officers, more attendants, smaller wards, and in many cases new buildings. All that the Commission had been able to do was to lay the considerations before Parliament in their report and to point out that the adoption of those recommendations would give a return, not only in actual dividends of the smaller number of lunatics to be maintained at the public expense, but in the quicker return to health of the citizens of the country. He thought that it was undoubtedly the case that in most of the rate-aided asylums at this moment it would be better to have a definite increase in the number of medical officers and a definite increase in the number of attendants. Wards were too large and individual attention was too difficult. But here he did not wish their lordships to be misled If they took the average asylum, say for 1000 cases, unfortunately there was a very large percentage of that population for which medical treatment was no use. There was the hopeless cases the advanced cases of general paralysis of the insane, the ordinary senile dements and so on. That class did not want an increase in medical attendants. There were other classes in perfectly good physical health such as paranoiacs, in which after a certain stage they ceased to have very much hope. But at the same time constant watchfulness and care and constant individual observation of those who they had any hope of preparing for discharge was the best and only way of getting maximum discharges from asylums. It was very early brought home to the Commission that the chief pride of the superintendent of an asylum was not the number of inmates that he managed to keep but the number that he managed to set free: that was what every doctor aimed at. The advances which had been made in the last 25 years had not been due to the Legislature, or even to the excellent work of the county councils who controlled these institutions but primarily to the initiative of the medical men themselves, who were constantly seeking to deal as best they could with these unfortunate cases. There was no drug that would cure it, nor any specific treatment; they could only put the patient in the best position to fight the disease himself. He put this point to one of the most distinguished doctors who came before the Commission, and he admitted that that was practically the position.

The Commission believed that the adoption of their recommendations might do a great deal to lessen the asylum population, because there were certain classes that could be cared for with less expensive treatment and less medical supervision and under such a system they thought there would be quicker discharges and also it might be possible to arrange to relieve asylums of the numerous cases where the patient could live outside the asylum with some friend or relative

He hoped that the Ministry of Health would consider the extent to which in any provisional treatment it was necessary to invoke the justices The justice was invoked because he was the representative of the public, and in consequence of the old and utterly fallacious idea that the doctor as an enemy of the human race was trying wrongfully to put an innocent man in prison But what could the poor justice do? He could only satisfy himself so far as he could by conversation with the doctor In some cases by actually seeing the man he could satisfy himself that it was an obvious case He did not deny that it was a safeguard, but one which in fact was not required, at any rate, in 99 cases out of 100 Whether it was necessary to keep the justice for the hundredth case, even in provisional treatment, he did not know, but he would suggest that an infinitely better safeguard than the intervention of any justice existed at the present time—namely, that the reception in an asylum of any certified lunatic had to be reported at once to the Board of Control, who had all the papers connected with the matter Another point to which he would call their lordships attention was the present rather curious position of what were called licensed houses, which were generally known as private asylums They were for private patients who could afford to pay as opposed to pauper lunatics, and at present the procedure for certification was rather different, and in some cases they had, perhaps, a little less protection There was a very natural and proper feeling on the part of the public that there was a possibility of danger in a place that was run by a proprietor for his own profit, and it was, of course, perfectly obvious that his duty and his interest might conflict This was a legitimate feeling, but he did not think that it had any foundation in fact But it seemed to him that the way to deal with that fear was not the way in which Parliament dealt with it in 1890 He supposed that the hope of Parliament in 1890 was that this vested interest would be gradually extinguished without compensation, but the results hoped for had not been achieved There were fewer licensed houses now than in 1890, but by no means so many fewer as to suggest that the process of extinction would take place within a reasonable time Parliament, when it legislated next time, must make up its mind whether the licensed house for mental patients was fit to exist or not If it was not fit to exist, Parliament must abolish it If it was fit, he thought that the Report of the Commission suggested that there should be what he called "free trade" in licensed houses, that was to say, subject always to the approval of the Board of Control, it should be possible to set up new licensed houses and the limitation on their creation should be abolished One advantageous effect would be that geographically they would be far better distributed than at present If, on the other hand, they were going to abolish the licensed house, it meant that rich people, when mentally afflicted, were not to be allowed to be treated where they chose They could not force such patients into the rate-aided institutions which accommodated pauper lunatics They would have to build public institutions out of public money which were not really needed Again, was a county council to provide accommodation at varying prices to suit the means of their paying patients? But if the accommodation was standardised it would be very much resented by the class affected

There was also the question of the Board of Control itself At the present time the Board of Control was very much understaffed It was urgent that they should have its members increased and have more people to do inspection work Even if the Government felt unable to do anything else with regard to the Report of the Royal Commission, he thought that they would have helped the matter if they increased the numbers of the Board of Control and by the experience gained help to shape the measure which they would, he hoped, at some time introduce He wished to ask the Government what hope there was of legislation being introduced and at what time? As the big subject of the Poor-law was not to be dealt with this session, was this not a good opportunity, at any rate, to introduce, perhaps, into their lordships' House a Bill dealing with this subject and carrying out such recommendations of the Royal Commission as commended themselves to the Government so that the public might have time to be instructed and to learn? If they were told that no effective legislation could be passed this year, they might, at least, be informed that towards the end of the session there might be presented in that House, if it was only for a first reading, some Bill embodying the conclusions at which the departments had arrived

Lord SANDHURST, speaking as one of the Lord Chancellor's visitors, said that the question of the necessity for early treatment of mental patients was almost a closed book so far as argument was concerned He would like to draw attention to the subject of voluntary boarders in registered hospitals. Something like a third of the patients in some of them were voluntary boarders In the licensed houses there were also a large number of voluntary boarders In Scotland, owing partly to a somewhat different interpretation of the law the number of voluntary boarders was even larger than in England, but a rate-aided patient could not be a voluntary boarder This was a case of one law for the rich and another for the poor and urgently called for reform. The Lord Chancellor attended in 1923 a meeting of the Mental After-Care Association, and at that meeting he foreshadowed the Mental Treatment Bill which was introduced in that year but failed to pass The Mental After-Care Association was one of the most deserving charities in the country, but the sort of care and observation which was very necessary should not be left to any charitable institution These two reforms urgently called for the sympathetic consideration of the Government There was another matter to which he wished to refer—namely the very natural hesitation which the medical profession felt in certifying patients. Recent cases had alarmed them and they felt that even when acting in the best of faith they were not adequately protected against subsequent legislation Cases were found in which it was clear that for the benefit of the patient, as well as of the public, it was desirable that the patient should be placed under supervision, yet it was very difficult to find medical men who were willing to certify The report suggested that the *onus* of proof in regard to good faith and reasonable care should be shifted and that it should be for the complaining patient to show that the medical man was actuated by bad faith and did not use reasonable care That would be a good thing as far as it went, but it was hardly enough to inspire confidence in the medical profession. At the same time he felt there was a great difficulty in going any further

Viscount GAGE, replying on behalf of the Ministry of Health, said he did not think the Ministry would disagree, at least in principle, with the majority of Lord Russell's remarks Although many of the results which the Commission set out to attain were in themselves universally admitted to be desirable, the steps that it would be necessary to take to bring those aims and objects into being might give rise to considerable controversy on grounds quite apart from the purely medical and scientific aspects involved. For instance, the prolonged litigation taking place in the Harnett case showed how far the legal status of the medical profession was involved in the law as it stood at present It also showed with what care it would be necessary to consider alterations of any kind in order to reduce to a minimum the possibility of similar cases arising out of the obscurity of the law The Government felt there was need for the very closest consideration of all the questions affecting this matter in all their aspects, scientific, legal, financial, and administrative, before they decided on their policy or enunciated it They thought that they were entitled to a longer period than had elapsed since the issue of the Commission's Report for the necessary investigations Until the Government's proposals for the reform of the Poor-law were in slightly more crystallised form it would be obviously almost useless to discuss the administrative side of the Commission's Report, which formed a considerable proportion of that report He could assure Lord Russell that the Minister of Health considered that there could be no dispute in regard to several of the principles which he mentioned, as, for instance, the desirability of treating the mentally afflicted at the earliest opportunity after the disability had become manifest, and also the desirability of removing the Poor-law stigma He could assure the noble earl that the Government regarded this report as a most valuable document and that they would not fail to adopt such of its recommendations as it might be found possible to do when the investigations of the Government were completed, and when they were in a better position to consider the relations of the report to their Poor-law reform proposals He would, of course, draw the attention of the Minister of Health to the suggestions which his noble friend had made

HOUSE OF COMMONS.

WEDNESDAY, FEB 23RD

Medical Officers at Naval Recruiting Centres

Sir BERTRAM FALLE asked the First Lord of the Admiralty the cost of maintaining medical officers at naval recruiting centres, and would he consider whether a saving could be effected by arranging for medical officers from naval depôts to visit these centres once or twice weekly for the purpose of medically examining candidates for entry into His Majesty's Navy —Lieut -Colonel HEADLAM replied There is a retired naval medical officer in receipt of a salary of £300 per annum at each of the six provincial headquarter recruiting stations At the London headquarter recruiting station an active service surgeon commander is employed and receives the pay of his rank. The travelling expenses, including subsistence, of medical officers travelling from the home ports twice weekly to Newcastle, Birmingham, Liverpool, Bristol, Manchester, and Southampton would be far greater than the salaries paid Moreover, the attendance of a medical officer only twice a week at a headquarter station would not meet requirements, as intending recruits must be examined when putting in an appearance, and this necessitates the attendance of a medical officer the whole of each working day

Physical and Medical Disability in Naval Recruits

Mr Hore-Belisha asked the First Lord of the Admiralty how many applicants were accepted in the year 1926 for His Majesty's Navy, and how many were rejected on account of some physical or medical disability —Lieut -Colonel Headlam replied The number of applicants accepted in the year 1926 for the Royal Navy was 6625, and for the Royal Marines 1063, a total of 7688 Separate totals of numbers rejected on account of some physical or medical disability cannot be given but the total number of candidates for entry in the Royal Navy and Royal Marines rejected on these accounts was 5427 This number does not include men and boys rejected by recruiters—i e , those not sent forward for final medical examination, of which there is no record

Bacteriological Laboratory in Fiji

Dr Shiels asked the Secretary of State for the Colonies whether he had considered the provision of a bacteriological laboratory and a qualified bacteriologist for the hospital at Suva, Fiji, in view of its importance as a medical centre for a wide tropical area.—Mr Ormsby Gore (Under Secretary for the Colonies) replied These suggestions have not previously been made to me, but I will communicate with the Governor

Accidents in the Air Force

Mr Day asked the Secretary of State for Air the number of Air Force personnel killed and injured in flying accidents since Jan 1st last to the last convenient date, together with the figures for the corresponding period of last year —Sir S Hoare replied The casualties to Royal Air Force personnel during the period Jan 1st to Feb 20th, 1927, were 8 killed and 14 injured , further, one naval officer and one naval rating were killed during this period The figures for the corresponding period of 1926 were 5 killed and 15 injured. I should add that four of the deaths in 1927 were the result of a single accident

THURSDAY, FEB 24TH

D C M S and Treatment of Pensioners

Dr Shiels asked the Minister of Pensions if he was aware that in the Edinburgh area there was an increasing number of cases of disabled ex-Service men who were being refused treatment by the D C M S and were being referred by him to their panel doctors who found them unfit for work and entitled to the National Health Insurance allowances , and would he see that more sympathetic consideration was given to these cases and hospital treatment with allowances given where deterioration had taken place —Major Tryon replied It is the duty of the Deputy Commissioner of Medical Services to prescribe whatever form of treatment he may consider necessary in a particular case, and in a case where no specialist treatment is called for, but attention from the general medical practitioner is all that is required, the pensioner is advised to consult the practitioner whose services are available to him under the Health Insurance Acts I should not be justified in requiring, as the hon Member suggests in the last part of his question, the provision of hospital treatment in all cases of deterioration, regardless of the medical view as to whether such treatment in a hospital were necessary or not With regard to the grant of allowances under Article 6 of the Warrant, I would remind the hon Member that the conditions governing the matter are not identical with those which determine sickness benefits under the National Health Insurance Acts

Medical Examination of Pensioners

Dr Shiels asked the Minister of Pensions if he had issued instructions that when the condition and circumstances of needy pensioners were being revised they were to be called up for medical examination by the Ministry, or was the certificate of a qualified medical practitioner still accepted as valid evidence —Major Tryon replied No general instruction to the effect suggested has been issued A certificate from the pensioner's own doctor is taken as evidence in support of a claim but if, as necessarily happens in some cases this evidence is not sufficient to enable the Ministry to determine the claim, an examination by a medical officer of the Ministry is directed

Street Processions for Hospital Funds

Mr Viant asked the Home Secretary whether he was aware that the West London Amalgamated Hospital Society had for many years organised processions, and collections had been taken en route for the purpose of helping the hospitals of London, and that by this means considerable sums of money had been obtained by a society of voluntary workers , that the society had been notified that in future collections could only be made at stationary points , and whether, in view of the fact that this new regulation would seriously affect the receipts, he would reconsider the matter.—Sir W Joynson-Hicks replied Before 1920 collections accompanying moving processions were entirely prohibited In 1920 the Regulations were amended so as to allow collecting processions in special cases, but experience has shown that these processions are liable to cause so much disturbance and interference with traffic that it was decided to amend the Street Collection Regulations so as to prohibit the practice I am sorry to have to put any obstacle in the way of collections for good objects, but the London traffic problem is now such that other considerations must be subordinated to traffic considerations.

Education Authorities and Mentally Defective Children

Mr Robert Morrison asked the President of the Board of Education how many local education authorities had made complete provision for the number of mentally defective children under their jurisdiction , how many had made partial provision , and how many had not yet made any provision —Lord Eustace Percy replied In the case of about 33 local education authorities the provision for the education in special schools of mentally defective children was fairly complete in 1925, the latest period for which returns are available , partial provision was made by some 175 authorities and 110 authorities had made no provision In addition about 50 authorities including some of those who had made no special school provision, had arranged for the supervision of mentally defective children in their areas

Mr Robert Morrison asked the President of the Board of Education the present estimated number of mentally defective children who might benefit by admission to special schools , how many of these children were at present in special schools , how many were in public elementary schools , how many in other institutions , and how many were not attending any school —Lord Eustace Percy replied . It is not possible to estimate the number of mentally defective children who might benefit by admission to special schools ; but of about 33,000 mentally defective children classed as educable in England and Wales, in 1925, 15,773 were attending special schools, 12,470 were at public elementary schools, 860 were at other institutions and 3872 were not attending any school The accommodation in mentally defective schools on March 31st, 1925, was 16,746 and on March 31st, 1926, 17,154

Poor-law Hospitals and Road Casualties

Mr Day asked the Minister of Health if his attention had been drawn to the increasing practice of admitting road casualties into Poor-law institutions, with the resulting cost of maintenance being thrown upon local funds , and would he consider legislation defining the powers of boards of guardians in respect of the maintenance of patients admitted to such Poor-law institutions after road accidents —Mr Chamberlain replied · I have received certain representations on this matter which are now under consideration

Patients in Mental Hospitals

Mr Day asked the Minister of Health the number of persons in mental hospitals and homes on Jan 1st, 1927 —Mr Chamberlain replied The number of persons certified in England and Wales under the Lunacy Acts resident in county or borough mental hospitals, registered hospitals, licensed houses and in single care on Jan. 1st 1927 was 116,748 There were in addition 796 voluntary boarders The number of mental defectives resident in institution and under guardianship on the same date was 22,759

Serum Treatment of Scarlet Fever

Mr Bennett asked the Minister of Health to what extent the serum treatment of scarlet fever and the Schick test and von Behring's method of immunisation against diphtheria were being used in this country by the various local authorities —Mr Chamberlain replied Exact figures are not available but the methods mentioned by my hon friend are being increasingly used throughout the country and with encouraging results I am advised that the serum treatment of scarlet fever is of value particularly in severe cases of the disease and in the prevention of its complications A fair number of local authorities especially the larger ones, now provide active immunisation against diphtheria for those who wish to avail themselves of it at child-welfare centres in schools in residential institutions, or among the nursing staffs of infectious diseases hospitals

Financial Position of Approved Societies

SIR **ARCHIBALD SINCLAIR** asked the Minister of Health whether he was aware that, owing to the increase in the amount of benefits paid by approved societies to their members during the past year and the decrease in the amount of contributions received from their members on account of the industrial crisis and from the State on account of the operations of Part I of the Economy (Miscellaneous Provisions) Act, a number of these societies, whose position at the beginning of this year proved to be actuarially sound, were now faced with the prospect of falling into deficiency before the end of the current quinquennial period; and what action, if any, the Government proposed to take to strengthen the financial position of these threatened societies —Mr **CHAMBERLAIN** replied · I am aware of the strain imposed upon certain approved societies by causes connected with the industrial crisis of last year I cannot, however, accept the hon Member's suggestion as to the consequences The valuations are separated by a period of five years, and I should not be warranted in drawing conclusions as to the results of the next valuation by reference only to the conditions prevailing over a few months In any case, the National Health Insurance Act enables the Central Fund to come to the aid of societies which have fallen into deficiency through no fault of their own, and I am satisfied that no further action by the Government is required So far as regards the reduction in the State contribution under the Economy (Miscellaneous Provisions) Act, I would refer the hon and gallant Member to Section 3 of that Act wherein very full provision is made for the protection of societies against the contingency to which he refers

Position of Local Health Visitors

Mr **GERALD HURST** asked the Minister of Health whether any association of nurses was consulted before the issue of the regulations of February, 1925, as to the position of health visitors employed by local authorities, if he was aware of the shortage of candidates under such regulations and the difficulties of nurses in complying therewith, and if he had considered the desirability of revising them —Mr **CHAMBERLAIN** replied The answer to the first part of the question is in the affirmative I am aware that there are not yet so many candidates under training for the position of health visitor as is desirable, but my attention has not been called to any particular difficulties in complying with the present regulations It is not proposed at present to revise the regulations which have been in operation only since April, 1925

Mental Deficiency Bill

Sir **JOHN MARRIOTT** asked the Minister of Health whether it was proposed to reintroduce the Mental Deficiency Bill this session and, if so, whether it would be introduced before Easter —Mr **CHAMBERLAIN** replied The Government do not propose to reintroduce the Mental Deficiency Bill But Mr B C Wood has presented a Bill which I understand will incorporate certain of the provisions of the Government Bill of last session

War Pensions Expenditure

Mr **DALTON** asked the Chancellor of the Exchequer the total sum paid in war pensions since the conclusion of the armistice —Mr R **MCNEILL** (Financial Secretary to the Treasury) replied The total sum expended on war pensions (including medical treatment but excluding administration) from the Armistice to March 31st, 1927, is estimated at *£647,000,000*

MONDAY, FEB 28TH

The Hours Convention

The House discussed in Committee the Washington Hours Convention on a vote of £11,653,564 for the Ministry of Labour Mr **HAYDAY** moved a reduction of £100 and called attention to the failure of the Government to ratify the Convention Sir A **STEEL-MAITLAND**, Minister of Labour, in reply, said that the matter was under the consideration of the Cabinet There was a wide variation in the interpretation of the Convention and in the practice of the countries that had ratified it They could not get a convention which would stand the test of practice until they had explored the ground and made it clear that the various countries meant the same thing and were going to carry it out in the same way He was trying to explore the ground and that was the only way they could get on the path of permanent progress

Dr **VERNON DAVIES** said he had a great deal of sympathy with the Minister of Labour, because he had formed the impression that the right hon gentleman was sincerely anxious to do all he possibly could towards ratification of the Convention, but that there were certain difficulties in the way He (Dr Davies) was a convinced believer in the efficiency and necessity for a 48 hours' week The Minister might, he suggested, promise to do all that he could to enter into a provisional ratification and that, if, after a certain time, other nations did *not ratify*, to repeal it The Government Front Bench showed a great lack of industrial psychology and if they would take a course in that, they would probably learn that the very fact of ratifying the agreement would cause such a tremendous feeling of thankfulness and relief among the working people that there would be peace in industry Eventually, the amendment was rejected by 199 votes to 108—majority 91

Indian Medical Service

Mr. **PETHICK-LAWRENCE** asked the Under-Secretary for India whether a decision had now been reached as to granting passage concessions to Indian officers who entered the Indian Medical Service by competitive examination in London —Earl **WINTERTON**, who replied, referred to an answer which he gave to Mr Day on Nov 9th The Secretary for India expected that details of the scheme recently sanctioned would be announced very shortly

TUESDAY, MARCH 1ST.

Vaccination Fees

Mr **GROVES** asked the Minister of Health whether the medical officer of health for Mexborough had performed any vaccinations during the recent small-pox outbreak, and, if so, what fee he had received or would receive for such vaccinations —Mr **CHAMBERLAIN** replied as follows This medical officer of health is also public vaccinator for Mexborough I have no information as to the number of vaccinations he has performed, but in his capacity of public vaccinator his fee for domiciliary vaccination is *6s* per case.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED FEB. 19TH, 1927

Notifications —The following cases of infectious disease were notified during the week Small-pox 346 (last week 479), scarlet fever, 1320, diphtheria, 955, enteric fever, 24, pneumonia 3523 (last week 3192); puerperal fever, 30, puerperal pyrexia 118, cerebro-spinal fever 15, acute poliomyelitis, 11, acute polio-encephalitis, 2, encephalitis lethargica, 39; dysentery, 10; and ophthalmia neonatorum, 111. No case of cholera plague or typhus fever was notified during the week

The cases of small-pox were distributed among the same English counties as last week, namely Cheshire 1, Derbyshire 6, Durham 217, Lancashire 5, Lincolnshire 1, Northumberland 11, Nottinghamshire 4, and Yorkshire 99 In addition, two cases were notified from Wales (from the counties of Monmouth and Glamorgan), and reference to an editorial article on p 506 will show that the Welsh outbreak has since assumed much larger proportions

Deaths —In the aggregate of great towns, including London, there were 2 (0) deaths from enteric fever 73 (1) from measles, 4 (1) from scarlet fever, 110 (26) from whooping-cough, 29 (7) from diphtheria, 51 (12) from diarrhœa and enteritis under two years, and 987 (128) from influenza The figures in parentheses are those for London itself The influenzal deaths for the last six weeks have thus been 326, 470, 725, 818. 759, and 990, whilst 1023 is the number notified for the week ended Feb 26th The figure for London however, has fallen to 81

ROYAL MEDICAL BENEVOLENT FUND —At the last meeting of the committee 34 cases were considered and £440 was voted to 29 applicants The following is a summary of some of the cases relieved —

Widow, aged 76, of L R C S Edin who died in 1893 Only income old age pension Lives with two sons the younger is unemployed and the elder finds it a hard struggle to keep three persons Voted £26 in 12 monthly instalments

Widow aged 63 of L R C P who died in 1917 Four children two married Eldest daughter, aged 38, is a domestic help, and comes home at night, she is *only* able to give her mother some provisions occasionally Son getting married, applicant asks for help as his money will cease Inclusive rent *7s 8d* a week Voted £18 in 12 monthly instalments

Widow aged 44, of M R C S who died in July last from septicæmia after an operation on a patient Two children boys, the elder, aged 20, earns *£65* per annum, and the younger, aged 8, is applying for an Epsom College Foundation When late husband s estate is settled estimated income will be about £110 per annum Voted *£20*

Subscriptions may be sent to the Treasurer, Sir Charters Symonds at 11, Chandos-street, Cavendish-square, London, W 1

Medical News.

UNIVERSITY OF OXFORD.—At a congregation held on Feb. 19th the following degrees were conferred:—

Doctor of Medicine.—Vincent S. Hodson.

Bachelor of Medicine.—Douglas A. Robertson, Clarence S. Broadbent, and Michael D. Bower.

SOCIETY OF APOTHECARIES OF LONDON.—At recent examinations the following candidates were approved in the undermentioned subjects:—

Surgery.—I. G. Briggs, London Hosp.; J. D. Evans, St. Mary's Hosp.; L. J. Lawrie, London Hosp.; A. W. Marsden, Birmingham; J. H. Mulvany, King's College Hosp.; W. D. Neill, London Hosp.; L. W. Rose, Guy's Hosp.; R. S. S. Smith, St. Bart.'s Hosp.; S. le R. Switzer, London Hosp.; and H. N. Walker, St. Bart.'s Hosp.

Medicine.—L. Ashkenza, Middlesex Hosp.; B. Best, Liverpool; I. G. Briggs, London Hosp.; J. De Rosa, Albany and London Hosp.; J. A. Fernandez and S. Jenkinson, St. Bart.'s Hosp.; R. Kahn, London Hosp.; J. H. Mulvany, King's College Hosp.; H. Rundstrom, St. George's Hosp.; and H. N. Walker, St. Bart.'s Hosp.

Forensic Medicine.—V. P. Bamford and I. G. Briggs, London Hosp.; J. De Rosa, Albany and London Hosp.; R. Kahn, London Hosp.; J. H. Mulvany, King's College Hosp.; and S. Wray, Manchester.

Midwifery.—I. G. Briggs, London Hosp.; J. D. Evans, St. Mary's Hosp.; K. E. Gallagher, Manchester; R. Kahn, London Hosp.; J. H. Mulvany, King's College Hosp.; S. Slotar, Guy's Hosp.; H. N. Walker and R. W. Wood, St. Bart.'s Hosp.; and S. Wray, Manchester.

The Diploma of the Society has been granted to the following candidates entitling them to practise medicine, surgery, and midwifery: B. Best, I. G. Briggs, J. H. Mulvany, L. W. Rose, H. Rundstrom, R. S. S. Smith, and S. Wray.

UNIVERSITY OF LONDON.—At a meeting of the Senate held on Feb. 23rd, the Vice-Chancellor, Sir William Beveridge, in the chair, the Cancer Hospital (Free) was admitted as a School of the University for a period of three years.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—A course of six Hunterian lectures on the Peoples of the East, Past and Present, is being given by Sir Arthur Keith, F.R.S., at the College. The remaining lectures will be delivered at 5 P.M. to-day, March 4th, and on March 7th, 9th, 11th, and 14th at the same hour.

SOCIETY OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At a council meeting of this Society the following resolution has been passed unanimously: "The Society of Members deeply deplores the great loss which it has sustained by the death of Mr. C. Edward Wallis, L.D.S., M.R.C.S. Eng., and desires to place on record its appreciation of his untiring zeal and self-sacrificing service on behalf of the Society and of all the members of the College."

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—A meeting will be held in the lecture theatre of the Society's house, 17, Bloomsbury-square, London, W.C. 1, on Tuesday, March 8th, at 8 P.M., when a lecture will be delivered on the Microscope and its Use in Research, by Mr. J. E. Barnard, F.R.S. Medical friends of members and student-associates will be welcome.

INDUSTRIAL HEALTH EDUCATION SOCIETY.—This organisation, which came into being last year, and has for its purpose the propagation among the British industrial population of information useful for the maintenance of health, held its first annual meeting in the Gould Hall, Edinburgh, yesterday afternoon. Sir William Haldane presided over a representative gathering, and the following appointments were made to the Council:—Chairman, Sir William Haldane (Edinburgh); Vice-Chairman, Dr. Charles Porter (M.O.H. Marylebone, W.); hon. secretary, Dr. G. Clark Trotter, (M.O.H. Islington, N.); hon. treasurers, Messrs. Greenhill and Clapperton (Edinburgh); and general secretary, Mr. J. Mackenzie, 89, Mibrae-road, Glasgow.

INQUESTS IN LONDON.—Last year 6934 deaths were reported to London coroners as against 6758 in 1925, and inquests were held in 5143 cases, in 80 per cent. of which post-mortem examinations were necessary. The total number of suicides was 600, as against 515 in 1925, and in two cases a verdict of felo-de-se was returned. Excessive drinking accounted for 28 deaths, and 18 were described as the result of want and exposure. Those recorded as due to lack of attention at birth increased from 36 to 57. In all 1761 people met their death by accident, as against 1607 in 1925. A verdict of death from natural causes was reported in 2117 cases and there were 10 verdicts of "Causes of death unknown." The total cost to the London County Council of the inquests held in 1926 was £25,732.

FIFTY YEARS A HOSPITAL SURGEON.—Dr. Thomas Porter Greenwood, of Stamford, Lincolnshire, has completed 50 years as honorary surgeon to the Stamford Infirmary.

Dr. K. B. Allan (senior medical officer) has been appointed by the King a Member of the Executive Council of the Gambia and an Official Member of the Legislative Council of that colony.

CHADWICK LECTURE.—On Thursday, March 10th, at 5.15 P.M., at the Barnes Hall of the Royal Society of Medicine, 1, Wimpole-street, London, W., Sir James Crichton-Browne will take the chair at the second of two Chadwick lectures by Dr. Carey F. Coombs, on Rheumatism: its Causes and Prevention. Information may be had from Mrs. Aubrey Richardson, at the offices of the Chadwick Trust, 13, Great George-street, Westminster.

MEMORIAL TO SIR PATRICK MANSON.—As we have already announced, Mr. Neville Chamberlain, Minister of Health, is to unveil a memorial tablet to the late Sir Patrick Manson in the Manson Ward of the Royal Albert Docks Hospital on Tuesday, March 15th, at 3.30 P.M. A train which leaves Fenchurch-street Station at 2.20 and arrives at Connaught-road at 2.41 P.M. will be found convenient.

ST. BARTHOLOMEW'S HOSPITAL: RETIREMENT OF THE MATRON.—At an "At Home" given by Lord Stanmore, the treasurer, last week, presentations were made to Miss McIntosh, the matron, who is retiring after more than 16 years' service. She was presented with an address and a cheque from the governors; the Guild of the hospital and the nurses gave her a diamond ring and other souvenirs.

LONDON FEVER HOSPITAL.—It was stated at the annual meeting last week that there was a large increase in the number of cases of measles in 1926, 208 patients being treated as compared with 39 in 1925. Of the 962 patients treated during the year 203 were suffering from pulmonary or other forms of tuberculosis.

CAMBRIDGE GRADUATES' MEDICAL CLUB.—The annual dinner of this club was held at the Langham Hotel, London, on Tuesday evening last, March 1st, Sir Humphry Rolleston, President of the club, in the chair. The occasion was made highly successful by the after-dinner performances of the St. Thomas's Hospital troupe who sang alone or in combination, played the ukulele, and improvised orations of an amusing character. Other members of the club added to the programme by recitations in metre, descriptive of amazing pathological occurrences.

BIRMINGHAM'S CRIPPLES.—An endeavour is being made to raise £50,000 for the extension of orthopædic work in Birmingham. Some two years ago the Royal Orthopædic Hospital in that city and the Birmingham Cripples' Union were amalgamated, and it is now the third largest curative institution in Birmingham. Yet there are still 500 cripples, more than half of them children, awaiting treatment. It is hoped to transfer all the bed cases to an open-air suburban hospital, which would give 40 more beds, and bring up the total number to 300.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—On Thursday, March 10th, at 5 P.M., Mr. R. H. Jocelyn Swan will lecture at the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, on Suppression and Retention of Urine. On Tuesday, March 8th, at 4.30 P.M., at the St. Mark's Hospital, City-road, Mr. W. B. Gabriel will give a demonstration in clinical surgery. Both lecture and demonstration are open to members of the medical profession without fee. The Brompton Hospital will hold a special week's course in diseases of the chest, starting on Monday, March 7th; there will be morning and afternoon sessions (fee £3 3s.). A special two weeks' course will be given at the Royal National Orthopædic Hospital from March 21st to April 2nd. The course will occupy the whole of each day (fee £2 2s.). From March 14th to 26th the Chelsea Hospital for Women will hold a special course in gynæcology, occupying the mornings and/or afternoons (fee £5 5s.). A late afternoon course in general medicine and surgery, primarily intended for general practitioners, will be held at the London Temperance Hospital from March 21st to April 2nd, lasting an hour and a half daily (fee £1 1s.). The Queen's Hospital for Children, Bethnal Green, will give a course in diseases of children from March 28th to April 9th from 10 A.M. to 4 or 5.30 P.M.; the wards and out-patient departments will be open continuously throughout the course (fee £3 3s.). In the afternoons for two weeks from March 28th, the Royal Eye Hospital will give a series of demonstrations on the Diagnosis and Treatment of Diseases of the Eye (fee £1 1s.). Copies of all syllabuses and of the *Post-Graduate Medical Journal* are obtainable from the Secretary of the Fellowship at 1, Wimpole-street, London, W. 1.

Dental Care of Liverpool School-children —The Liverpool Education Committee has decided to appoint two whole-time dental officers for the city at salaries of £500 per annum rising to £600 instead of the present part-time service

Walsall Maternity Home —Hitherto the County Borough of Walsall, with a population of about 100,000, has lacked a maternity home The corporation have now purchased Bloxwich Manor House, which is within the borough, and it is to be adapted for that purpose

Gift to University of Edinburgh —Mr Thomas Cowan, a retired shipowner of Leith, has given £15,000, in addition to £10,000 previously given, to enable the University to provide a residential house for male students Houses will be purchased in George-square and adapted to accommodate about 125 students

Shortage of Radium in Liverpool —At the annual meeting of the Liverpool Hospital for Cancer and Skin Diseases a proposal to provide Liverpool with a supply of radium for cancer treatment at a cost of £30,000 was put forward It was stated that the hospital at present possessed only £1000 worth of radium, indeed, the city had so little radium that patients needing this form of treatment have to be taken to the Christie Hospital in Manchester

Rebuilding Scarborough Hospital — The governors of Scarborough Hospital and Dispensary (50 beds) have abandoned their intention of enlarging the building to provide double the number of beds They find that the present form of the hospital and the present site cannot adequately meet modern needs and have therefore decided to build an entirely new hospital on a fresh site

Manchester, Baguley Sanatorium—Asst M O £350
Manchester Salford Royal Hospital—Two H S's Each at rate of £125
Middlesex Hospital, Mortimer-street, W—Asst Radiologist £100
National Hospital for Diseases of the Heart, Westmoreland-street W—Res M.O Also Out-patient M.O At rate of £150 and £125 respectively
Newcastle-upon-Tyne, Hospital for Sick Children—Sen and Jun Res. M O's At rate of £120 and £100 respectively
Nottingham City Mental Hospital—Jun Asst M O £350
Oxford Radcliffe Infirmary and County Hospital—H P and Cas H S Each at rate of £120
Plymouth South Devon and East Cornwall Hospital—Res Surg O, H S, H.P. At rate of £100 and £50 respectively Also Cas H S
Prince of Wales's General Hospital Tottenham N—Two H S's and H P At rate of £120 Also Jun. H S and Jun. H P. At rate of £90
Queen's Hospital for Children, Hackney road, Bethnal Green, E—H P At rate of £100
Richmond, Surrey Royal Hospital—Asst H S At rate of £100
Royal Free Hospital, Gray's Inn road, W C (Children's Dept)—First Asst for Infant Welfare, &c
Royal National Orthopædic Hospital, 234, Great Portland-street, W—H S At rate of £150
Royal Waterloo Hospital for Children and Women Waterloo road, S.E—Hon Surg Reg and Hon Orthopædic Surg
St John's Hospital Morden Hill, Lewisham, S E.—Res Cas O At rate of £100
St Mary's Hospital, Institute of Pathology and Research—Research Studentship £200.
St Peter's Hospital for Stone, &c, Henrietta street, Covent-garden, W C—H S At rate of £75
Samaritan Free Hospital for Women, Marylebone-road, N W—H S At rate of £100
Sheffield, Winter-street, Hospital for Tuberculosis—Res M O £350
Southampton Royal South Hants and Southampton Hospital—Jun. H.S At rate of £150
Stockton-on-Tees Stockton and Thornaby Hospital—Sen. R.M.O, Also Second R.M.O and Jun. R.M.O £175, £150 and £125 respectively
Surrey County Council—Asst. M O in Public Health Dept £600
Sydney University, New South Wales—Director of Cancer Research £2000
Wellhouse Hospital, Barnet—Asst Res M.O £250
West London Hospital, Hammersmith-road W—H P and two H S's Each at rate of £100 Also Hon Med. Reg £100
Winchester, Royal Hampshire County Hospital—Hon. Surg in Ordinary
Worcester General Infirmary—Jun. Res M O £120

The Chief Inspector of Factories announces the following vacant appointments for Certifying Factory Surgeons Aylsham (Norfolk), Tideswell (Derbyshire), and Linton (Cambridgeshire)

Births, Marriages, and Deaths.

BIRTHS

ADAMS—On Feb 18th, the wife of Dr David Rutherford Adams, Linden Lodge, Torquay, of a daughter

BRIGGS—On Feb 23rd, at Hawes Hill Farm Holyport, Berks, the wife of Percy J Briggs, M.A., M.R.C S, L.R.C.P, of a son

PANTON—On Feb 23rd at Lindisfarne-road, Newcastle-on-Tyne the wife of Major H F Panton, R.A.M.C, of a daughter

RAYNER.—On Feb 24th, at The Ledge, Hythe, Kent, the wife of Dr E C Rayner, of a daughter

THOMSON—On Feb 23rd, at Woodland House Penrith, Cumb, the wife of Douglas D C Thomson, M.R C S, L.R.C P, of a daughter

MARRIAGES

McDONALD—BRIGHT—On Feb 17th, at the Register Office of St. Giles Bloomsbury W C, Niel McDonald M.B Ch.B Vict. M.R.C S Eng, L R C P. Lond., to Hilda Gladys May Bright, B.A., A.R.C M.

DEATHS.

BEVEN—On Feb 18th, at High road, Lee, S E., Octavius Beven, M.D, B S, D.P H, aged 57

BOURKE.—On Feb 19th at Moreton-gardens, South Kensington, William Henry Bourke M.D

COOK.—On Feb 20th at Poole-hill, Bournemouth Issac Reginald Cook, M.B, B S Lond.

HILLIER.—On Feb 22nd at 396 Ecclesall road Sheffield, Robert John Hillier, M.R.C S, L.R C.P, aged 58

LE CRONIER—On Feb 19th at Queen's avenue Jersey Hardwick Le Cronier M R.C S, L.R C P in his 71st year

LONG—On Feb 23rd at The Close, Norwich Frederick Long, M R.C S, L.R.C P, formerly of Wells, Norfolk, in his 87th year

ROSS—On Feb 18th, at Norwood Invergordon N B, George Ernest Ross, M.A., M.B, Ch.B, late of Bishop Auckland.

N B—A fee of 7s 6d is charged for the insertion of Notices of Births, Marriages, and Deaths

advocates of Weismannism hold that the germ-plasm is not only "continuous" but that it is proof against such influences. I am of the opinion that there is clear evidence that such an impairment does actually occur.

Secondly the results of this impairment of the germ-cell are influenced by the condition of the cell which it fertilises or by which it is fertilised. This raises the question of the mode of hereditary transmission—namely, whether this is in accordance with Mendelian laws or whether it is by blending. Numerous attempts have been made to show that mental disease and particularly mental defect is a Mendelian unit which is transmitted according to Mendelian laws. In my opinion these attempts have completely failed and I think the evidence is strongly against the impairment being a Mendelian unit and in favour of the condition of the zygote being a blending of the developmental potentiality of the two gametes. I think therefore, that if there is a similar impairment of the combining cell the developmental potentiality *of the embryo will be still further reduced* but that if this cell is healthy the developmental impairment will tend to be lessened.

Thirdly, since inheritance is of developmental tendencies only, the environment will play a part in their realisation. Adverse factors of the environment which are in operation before the development of the brain is complete may still further embarass that development and accentuate the tendency to imperfection. Factors acting after the completion of development may render any latent defect of durability patent and may cause the mental breakdown of an individual in whom the predisposition is only slight and who might otherwise go through life apparently normal.

Impairment or Devitalisation of the Germ-cell

The view I put forward, therefore, is that (with the exception of those cases which are directly caused by the environment) the various forms of mental defect, disorder and decay are manifestations of one and the same condition—namely, an impairment or *devitalisation of the germ-cell*. This occurs in varying degrees: when severe it causes brain development to be so incomplete that the individual is mentally deficient. When less pronounced brain development may take place normally, and the temple of mind may be erected but the structure is so lacking in durability that it at once begins to crumble away and dementia precox results. When the germ impairment is of still less degree mind is completely developed and may function normally for many years: indeed, should the individual live in sheltered surroundings it may do so for the whole span of life: but exposure to mental stress or physical illness or the changes incident to the climacteric or other critical period of life will be very prone to result in a breakdown and this in many cases will be the beginning of a steadily progressive dementia.

As I have pointed out however, two other factors have to be taken into account—namely the condition of the second or combining germ-cell and the nature of the environment especially during the early and rapid stage of brain growth. If the second cell is healthy and the early surroundings entirely favourable I think that a slight degree of impairment may be entirely neutralised it may even be "bred out." On the other hand, if the second gamete is similarly impaired there will be an accentuation of the process and a tendency for the developmental potentiality and durability of the brain cells to be still further lessened. This may itself give rise to mental defect or defective development may result from the operation of some comparatively trivial environmental factor.

It is clear that combinations of these three factors—namely variations in the degree of germ impairment the condition of the combining cell and the nature of the environment will be responsible for very varying results in different individuals derived from the same stock or belonging to the same family. It is well known that these differences occur and they are a cause of much perplexity, but I think they are explicable on this view. It not infrequently happens that an individual who has inherited the neuropathic diathesis mates with one who is similarly tainted. There is then a predisposition for the mental impairment to assume a more severe form in the next generation or to occur at an early period of life a process which is called "ante-dating" and which has long been known to mental specialists. The final result of this process is pronounced mental defect with sterility and extinction and hence I have termed idiocy the logical culmination of the neuropathic diathesis. In other instances a victim of the neuropathic diathesis mates with an individual who is healthy. Their offspring although carrying the taint and probably showing some impairment of mental capacity and resistance may not actually suffer from mental disease. But the fire is only smouldering and should one of these in turn mate with a neuropath or should he or his offspring be exposed to some adverse environmental influence, it may readily be fanned into a flame and dementia insanity, or mental defect result. In this way mental disease is kept alive by "carriers" who may themselves appear to be normal or who at all events do not suffer from a degree of abnormality which would be recognised as disease.

In giving this short outline of the genesis and mode of production of mental disease I wish to make it quite clear that I am only advancing a working hypothesis. The complexity of the subject is great and there are many gaps in our knowledge, but I venture to think that the hypothesis is a logical one and that it does afford an explanation of facts which are otherwise extremely perplexing.

Mental Disease and Genius

We have now to consider the bearings of mental disease upon eugenics. At the outset *it is necessary* to allude to a prevalent misconception regarding the relationship of mental disease to genius. Since Dryden proclaimed that: "Great wits to madness nearly are allied, and thin partitions do their bounds divide," it seems to have been commonly assumed that genius is so intimately connected with insanity that we must cheerfully put up with the latter for the sake of the former, and that any attempt to diminish mental disease by restriction of propagation may have the disastrous result of robbing the world of a possible superman. Now I fully admit of course, the great benefits which have resulted to mankind from the works of men of genius; it is indeed to the existence of such men of outstanding ability in the various departments of human knowledge, thought, feeling and action that we largely owe our past progress and our present civilisation. There is also no doubt that some of these men have been of poor physical constitution and prone to ill-health, whilst others have been eccentric and possessed of delicately balanced minds. But I have searched in vain *for any* close correlation between genius and insanity, and I believe the commonly accepted view that such exists to be a completely mistaken one. On the contrary, I think it will be found that the great majority *of men and women of outstanding ability* have been particularly sane and have come of a sane and healthy stock. It is, therefore an utter fallacy to assume that the elimination of mental disease would mean the elimination of genius, and I am in complete agreement with the views on this point expressed by Major L. Darwin in his valuable work on "Eugenic Reform."

The Damage to the Race inflicted by Mental Disease

On the other hand there is clear evidence that mental disease is closely correlated with social incapacity, inefficiency, and retrogression. And serious as is the damage done by mental disease to the present generation, I believe that inflicted upon the race to be even greater. *There* can be no question that one thing which is urgently needed is the prevention of the propagation of those persons who suffer from any form of mental disease due to inheritance.

In the case of mental defectives two methods for preventing this propagation have been suggested—namely, sterilisation and segregation. This is not the place to discuss in detail their respective merits. I will merely say that after careful consideration of all the points involved such for instance as practicability cost the happiness of the defectives and the effect upon the community of the release from care of persons who are incapable of caring for themselves I have come to the conclusion that the advantages of segregation far outweigh those of sterilisation. In saying this I realise that there are *many persons suffering* from the milder grades of mental defect who are not themselves in need of institutional care and in whose case the chief danger is propagation. Even here I consider that there are abundant reasons *against* sterilisation, and I believe that if ascertainment were only properly carried out so that the whereabouts of each person was known: if every person not in an institution was placed under statutory supervision and the methods of such supervision improved so that he could be removed to an institution should circumstances arise to make this desirable, and if the marriage of mental defectives was made illegal, the risk of propagation would become practically negligible.

It is necessary to point out, however that even if, by sterilisation or segregation or supervision, we *could* absolutely prevent propagation by defectives we should by no means eliminate mental defect *or disease indeed it is very* doubtful if we should produce any considerable effect at all. For in spite of the fact that approximately 80 per cent. of such cases are due to inheritance, the proportion who are the *offspring* of a *mentally defective parent is a* very small one. The great majority of defectives are produced by parents who have either been insane, or have been carriers and have not been certifiable at all. The sterilisation or segregation of every *defective* would merely prevent the birth of that relatively small number who are the offspring of parents who are themselves defective. I think that if it were possible to apply either of these methods to the insane the effect would be considerably greater for propagation by the insane is much more extensive than by defectives, but even then we should be a long way from the eradication of mental disease In order to produce any really marked diminution in the amount of mental disease throughout the community it would be necessary to sterilise or segregate every carrier of the neuropathic diathesis, which is obviously impossible

But were it even possible to do this, we should be faced with another difficulty There is every reason to think that the causes of germ impairment are still at work, and, this being so, a fresh crop of persons suffering from the neuropathic diathesis would soon come into existence Although we have succeeded in removing some of the causes, and are in process of removing others, it seems likely that every change in social conditions and every advance in evolution brings in its train certain inimical agencies which may produce impairment of the germ-cells of those individuals who are unfit to continue the march I have little doubt that for many generations to come devitalisation of the germ-cells and the neuropathic diathesis will continue to be produced It is possible that this process may even be a salutary one and that if only such affected persons could be prevented from contaminating the healthy, it might, in the long run and from the racial point of view, be productive of good rather than harm Unfortunately nothing is done to prevent such contamination, and there is a very real danger of the dragging of sound stocks into the vortex of disease and of the diffusion of the impairment throughout the mass of the community

The Need for Education in Eugenics

What, then, is to be done? My own feeling is that there is one way, and one way only, by which we can hope to stem degeneracy and advance racial progress That way is by an educational campaign whereby the whole community shall be enlightened as to the part played by inheritance in the causation of health and disease, in other words, by developing throughout the nation the eugenic ideal By the eugenic ideal I mean not merely the intellectual recognition of the desirability of producing sound and healthy offspring, but a feeling, or an emotion, regarding this idea, a sense of shame and repugnance at the thought of bringing into the world delicate and defective children, a sense of satisfaction, of increased self-respect, and of duty well done at the thought of producing children who are healthy and capable This may sound unpractical, perhaps, to some persons even fantastic, but I do not think it is either In terms of psychology such an ideal constitutes a sentiment and the human mind has a great capacity for acquiring sentiments It has already developed the religious and the aesthetic sentiments to a very high degree, and, just as all moral and cultured persons now feel deep repugnance at the idea of committing a crime, or when confronted with a disharmony in music, colour, form, or social decency, so I believe it to be equally possible for them to develop the eugenic sentiment, or if we prefer so to call it, conscience

No doubt our knowledge is far from complete, but there is quite enough to go upon, and I think the education of the nation should be the main objective of this society It is impossible to conceive of any more important task or of one which would be attended with greater benefit For it does not admit of any question that in the last resort the very existence of a nation must depend upon the condition of its citizens, and it is extraordinary that a people which prides itself upon its sound common sense and business capacity should be content to spend millions upon the cure, care, and maintenance of persons suffering from disease, and take practically no steps to prevent it at its source

A CORRECTION.

To the Editor of THE LANCET

SIR,—In recording (THE LANCET, Feb 26th) the gratifying appointment of Colonel J G Martin to be honorary physician to the King, you say "It is understood that this is the first time this honour has been granted to a Territorial officer" Your informant must, I think, have been under a misapprehension, for in fact such appointments have been regularly made from the Territorial Army for a number of years

I am, Sir, yours faithfully,
X Y Z
March 1st, 1927

UNITED STATES MEDICAL SERVICES

THE annual reports of the Medical Directors of the United States Army, Navy, and Public Health Service are summarised in the *Military Surgeon* for February The Surgeon-General of the Public Health Service gives the death-rate in 30 States (out of the 48) as 11 7 per 1000 The case-mortality of small-pox was over 30 per cent in Washington and Minneapolis (470 cases), whilst in Indianapolis and Omaha there was no death among 1000 patients In a population of 100 millions (36 States) the death-rate from tuberculosis was about 0 82 The mortality from typhoid slightly increased, but the programme for controlling venereal disease is believed to have been a great success Numerous activities of the service are mentioned, and accounts are given of how it fought plague-infected rodents in California, and how it used aeroplanes to spread arsenical dust on lakes to control malaria by destroying the larvæ of mosquitoes Immigrants are now inspected before they leave Europe, but immigration inspection is still continued at ports in the United States, as all foreign seamen must be examined as prospective immigrants In 1925 there were 872,842 foreign seamen so examined

In the United States Army in 1925 there were 983 medical officers in charge of the health of 135,840 men This gives a ratio of 1 to 138, and the Surgeon-General thinks that the medical strength should be higher Admissions for disease amounted to 518 per 1000, whilst the total death-rate was 3 77, of which 1 71 was accounted for by disease The lowest mortality in any group was actually among the white troops in Panama, which shows what skilled sanitation can achieve The death-rates from pneumonia and tubercle were almost identical at about 0 23 per 1000, whilst suicide (0 31 per 1000) was the highest single cause of death Invaliding was 17 per 1000, but half those invalided were in their first year of service Invaliding for tubercle was 1 72, whilst for mental disease the rate was three times higher There were four cases of typhoid with two deaths Athletics occasion many admissions for injury In ten years before the establishment of a dental corps (1887-97) there were 36 cases of arthritis per 1000, but in the last five years the figure has been only 13 Thanks to the inspection of milk and meat by the Veterinary Service, 97 2 per cent of the animal food condemned was dealt with before purchase, which meant a great saving to the Government The annual physical examination of officers is said to be so generally approved that reserve officers are asking that it may be extended to them

The United States Navy had in 1925 about 113,000 men, admissions were 531 9 per 1000 from all causes; the death-rate was 3 60 (from disease 1 53) There were only four cases of typhoid and general hygienic conditions were described as good

HUNTER AND ABERNETHY.

To the Editor of THE LANCET

SIR,—Sir Berkeley Moynihan's Hunterian Lecture to the Royal College of Surgeons of England on Hunter and Abernethy was revealing with its wealth of illustration and rare vision We may well rejoice that we have as President of the College a man of liberal education whose theme is Life

But there is one point I would like to make Notwithstanding Abernethy's evidence of Hunter's "heavy delivery and unengaging," I cannot but believe that Hunter was eloquent and not unattractive "Sincerity is the foundation of expression in writing" said John Morley, and surely it must be so in speech There are different kinds of accent Livingstone was only a stuttering orator, and how gladly we would listen to the sincerity of a Livingstone or a Hunter

I am, Sir, yours faithfully,
RICHARD GILLBARD
Willesden Green, Feb 28th, 1927

The History of Harley Street—In an annotation with this title (THE LANCET, Feb 26th, p 449) we stated that Sir William Jenner was the first consultant to take up his residence in Harley-street Mr Percy Flemming, in his address at the Royal Society of Medicine, described him only as one of the earliest to go there, he was the first member of the University College Hospital staff to make the move

VOLUNTARY HOSPITAL POLICY—Speaking at the annual meeting of the General Lying-in Hospital, Lambeth, last week, Lord Onslow, Under Secretary for War, said that the Government were firm supporters of the voluntary hospital system, and expressed his belief that the grant of £500,000 towards meeting the maintenance deficits from which the hospitals were suffering after the war had not only not harmed the voluntary principle but had benefited it by setting up local committees

OPHTHALMOLOGY IN DORSET—The Society of Dorset Men in London has presented a new ophthalmic department to the Dorset County Hospital, Dorchester, in memory of the first hon secretary of the Society, the late Mr William Watkins Sir William Lister, in a speech at the opening ceremony, said that he did not believe that the sight of the nation had deteriorated, and that the contrary impression was based upon the fact that children's eyes were now for the first time being cared for

Goulstonian Lectures

ON

CARDIAC DYSPNŒA.

The First Goulstonian Lecture in 1927, delivered before the Royal College of Physicians of London on March 10th

BY FRANCIS R FRASER, B.A CAMB, M D,
F R C P. EDIN, F R C P LOND,
DIRECTOR OF THE MEDICAL PROFESSORIAL UNIT, ST BARTHOLOMEW'S HOSPITAL, PROFESSOR OF MEDICINE IN THE UNIVERSITY OF LONDON

LECTURE I

IN selecting the subject of the lectures I have chosen cardiac dyspnœa, a symptom present in many diseased persons, because a number of observations bearing on this subject have been made in the last few years in the department under my direction by several members of the staff.

In considering the disturbances of respiration that result from disease, the respiratory apparatus may be regarded as consisting of the following structures (*a*) the respiratory centre situated in the medulla oblongata; (*b*) the lungs, respiratory passages, walls of the thoracic cavity, and the muscles of respiration forming the respiratory mechanism, and (*c*) the blood and the circulatory apparatus

The respiratory centre sends impulses to the muscles of respiration, which so alter the size of the thoracic cavity that the lungs expand and contract alternately, and the air sacs within the lungs are kept supplied with air from the external atmosphere through the respiratory passages By this means the blood circulating through the lungs continually takes up oxygen from the air sacs, and being then distributed to the tissues of the body supplies these with the necessary oxygen for their needs, and taking up carbon dioxide from the tissues carries it to the lungs, where it passes into the air sacs and so into the external atmosphere.

That the necessary amount of oxygen may be economically supplied to the tissues of the body under the varying conditions of normal life, and the carbon dioxide efficiently removed, a close coördination between the respiratory centre and the blood-flow is essential Increased activity of the body requires increased oxygen-supply, and results in increased blood-flow and increased ventilation of the air sacs This increased ventilation is the result of increased activity of the respiratory centre The variations in pulmonary ventilation that necessarily are taking place all the time in normal life are not noticed by the individual They do not give rise to consciousness of their occurrence Extreme degrees of increased respiratory activity, however, in healthy individuals give rise to unpleasant sensations called breathlessness or dyspnœa In diseased states dyspnœa may occur much more readily than in health In diseased states subjective distress will result from an increase in activity of the body that in health would cause no change of which the individual is conscious, though in health an increase of respiratory activity and an increase in ventilation have occurred As Means[1] has pointed out, it is only when the respiratory mechanism cannot perform the task demanded of it that the movements enter the field of consciousness He states "Dyspnœa will occur whenever the respiratory mechanism cannot with ease functionate to the extent that bodily processes require" Increased respiratory activity without distress or consciousness of effort may be termed hyperpnœa, and this is present at some stage previous to the development of dyspnœa—at any rate, in health In disease, however, there may be dyspnœa without actual increased ventilation—for example, in the presence of lesions of the respiratory mechanism that mechanically prevent increased ventilation By adopting this conception of dyspnœa, an analysis of the causes of dyspnœa involves, as Meakins and Davies[2] have pointed out, the consideration of: (1) factors causing increased pulmonary ventilation or hyperpnœa, and (2) factors causing inability of the respiratory mechanism to meet the demands for increased pulmonary ventilation, and so distress

INCREASED VENTILATION.

In his book on "Respiration" J. S. Haldane[3] has discussed very fully the factors that may affect the respiratory centre to cause increased respiration. These factors may be divided into chemical and nervous The chemical factors that are known to influence the activity of the respiratory centre are. (1) the pressure of oxygen; (2) the pressure of carbon dioxide, and (3) the H-ion concentration in the blood supplied to the centre

It may be assumed that in healthy individuals the partial pressures of the gases in the arterial blood are almost equal to the pressures of these gases in the alveolar air, and the pressures in the alveolar air can be varied by varying the composition of the inspired air Lowering of the pressure of oxygen in the inspired air, as occurs gradually in balloon ascents, &c, is not accompanied by altered respiration, but a rapid lowering of the oxygen in the *inspired* air results in *immediate and severe* hyperpnœa. Haldane and Poulton[4] showed that the failure of a gradual reduction of oxygen to cause noticeable hyperpnœa is due to the gradual lowering of the carbon dioxide pressure that results from the slight increase in ventilation that takes place, and that this lowering of carbon dioxide pressure has not time to occur in the rapidly produced lowering of the oxygen tension. They concluded that the effect of reduced oxygen pressure in the arterial blood is to lower the threshold of the centre for carbon dioxide, so that it is stimulated by lower carbon dioxide pressures when oxygen deficiency is present Haldane, Meakins, and Priestley[5] investigated the respiratory response to lowered oxygen pressures and concluded that "the respiratory response to oxygen-want is in three stages (*a*) increased depth of respiration and increased ventilation per minute, owing to lowered carbon dioxide threshold; (*b*) periodic breathing, unless the oxygen-want is considerable; and (*c*) frequent and correspondingly shallow breathing" These conclusions, based on observations involving the reduction of the oxygen pressure in the arterial blood, may be accepted as the effect of oxygen-want on the respiratory centre no matter how produced. In any condition in which the supply of oxygen to the tissues of the centre is not sufficient for the needs of the centre these effects may be expected.

Haldane and Priestley[6] showed that changes in the carbon dioxide pressure in the alveolar air cause pronounced changes in ventilation. An increase of carbon dioxide pressure of 1 5 mm over the normal 40 mm. of Hg doubles the pulmonary ventilation, and a fall of the same extent causes apnœa This action is independent of afferent nervous stimuli to the centre, and is due to the changes in the carbon dioxide pressure in the arterial blood supplied to the centre There is still much doubt as to whether this action is a specific one due to carbon dioxide or whether it is an action common to all acids

Beddard, Pembrey, and Spriggs[7] showed that excessive breathing is characteristic of the state of acidosis, and this led to the appreciation of the fact that a rise of hydrogen-ion concentration in the arterial blood due to any acid acts as a stimulant to the respiratory centre The addition of a fixed acid, such as occurs in the ketosis of diabetic coma, results in a combination of the acid with base, so that less base is available for the carriage of carbon dioxide Thus will cause a rise in the ratio of dissolved carbon dioxide to combined carbon dioxide Hasselbalch[8] showed that this relationship—the ratio $H_2CO_3/NaHCO_3$—is the most important indication of the hydrogen-ion concentration in the blood. A lowering of the denominator due to the abstraction of base to combine with an increase of some fixed acid will result in an increase in the value of the ratio and an increase of hydrogen-ion concentration until the carbon dioxide pressure, and therefore the volume of dissolved carbon dioxide—the numerator in the ratio—can be lowered by increased respiratory activity Lowered carbon dioxide pressure in the alveolar air will thus be produced, with lowered pressure and lowered volume of carbon dioxide in the arterial blood, until the ratio returns to its original value

In this way it seemed possible to regard the effect of carbon dioxide on the centre as an effect of change in hydrogen-ion concentration rather than a specific effect of carbon dioxide Hooker, Wilson, and Connett,[9] however, showed that blood at a given hydrogen-ion concentration with a high carbon dioxide pressure caused a stronger stimulation of the respiratory centre than blood at the same hydrogen-ion concentration with a low carbon dioxide pressure This suggested a specific action from carbon dioxide, and Scott [10] and Collip [11] came to similar conclusions The work of Jacobs [12] allows of a reconciliation between these opposing views He demonstrated that dissolved carbon dioxide has a greater power of penetrating cell membranes than combined carbon dioxide has This fact would account for the apparent greater influence of carbon dioxide compared with other acids, and permits the conclusion that the real stimulus is the hydrogen-ion concentration within the tissues of the respiratory centre itself In health the hydrogen-ion concentration at the centre will no doubt be mainly regulated by the condition of the arterial blood, but it is the condition in the centre itself that determines its activity

Whether increased breathing is the result of increased carbon dioxide in the arterial blood, or of an increase of fixed acids, or of oxygen-lack, may be determined by an examination of the arterial blood In the first case there will be an increase in the content of the carbon dioxide in the blood and a high carbon dioxide pressure When the stimulation is due to an increase of fixed acids, there will be diminished carbon dioxide content and a lowered carbon dioxide pressure through increased ventilation In both cases the stimulus to the centre will be a raised hydrogen-ion concentration and the arterial blood will be saturated with oxygen to the normal extent When hyperpnœa is due to oxygen-lack in the arterial blood, and the resultant lowering of the threshold of the centre to carbon dioxide pressure and to hydrogen-ion concentration, the arterial blood will show a lowered carbon dioxide content and pressure from increased ventilation and a lowered hydrogen-ion concentration, and will be saturated with oxygen to an extent less than normal If, however, there is increased breathing due to some stimulus at the centre other than an abnormality in the quality of the blood supplied to it the examination of the arterial blood will show normal saturation with oxygen, low carbon dioxide content and pressure, and low hydrogen-ion concentration These differences are shown in Table I

Table I

Cause of hyperpnœa	Changes in arterial blood			
	O_2 saturation	CO_2 volume	CO_2 pressure	H-ion concentration
O_2 lack in arterial blood	Low	Low	Low	Low
CO_2 excess in arterial blood	Normal	High	High	High
Fixed acids in excess	"	Low	Low	"
Stimulus at centre independent of quality of arterial blood	"	"	"	Low

On the examination of the arterial blood in cases of hyperpnœa single observations give results that occasionally indicate one of these conditions to be present As a rule, however, this is not so, since the body cannot be considered as a respiratory system only Changes in the reactions of the tissues generally and of the renal organs especially, take place at the same time as the respiratory functions are disturbed or as a result of the disturbance Henderson an Haggard [13] showed that in the presence of an altered carbon dioxide pressure in the blood a readjustmen of base takes place between the tissues and the blood, so that the amount of alkali available for th carbon dioxide is altered The alteration is in such a direction that changes in the hydrogen-ion concentration are prevented or are minimal In the diseased states in which hyperpnœa occurs more than one of the type conditions may be present—for example, in pulmonary lesions both oxygen-lack and raised carbon dioxide pressure may be present—and kidney disturbances with faulty excretion of acid bodies may be present at the same time as pulmonary or circulatory abnormalities

There is evidence pointing to influences on the respiratory centre by afferent nervous impulses The reflex of Hering and Breuer [14] acts through the vagus, and consists of afferent impulses consequent on the act of inspiration whereby inspiration is checked and expiration occurs The stimulus for these impulses is unknown, but the stretching of the lung substance has usually been regarded as the effective agent The removal of these afferent impulses by section or freezing of the vagi results in slower and deeper breathing

Laqueur and Magnus [15] demonstrated that rapid breathing results in animals from the inhalation of phosgene gas Dunn[16] showed that rapid breathing resulted when a fine emulsion of potato starch was introduced into the pulmonary circulation and produced obstruction of capillaries or of the finer arterioles This rapid breathing was independent of oxygen-want, and was abolished by section of the vagi Binger, Brow, and Branch[17] repeated Dunn's experiments and confirmed his observations They showed that section of the vagi converted also the increased breathing that resulted from oxygen-want or carbon dioxide excess into a slow deep rhythm, and give reasons for doubting that the rapid breathing is due to afferent stimuli of the centre. In their opinion structural changes in the lung substance limited the variations in lung volume on inspiration and expiration and produced shallow breathing, and that the shallow breathing led to rapid breathing through the Hering-Breuer reflex It is doubtful whether such rapid breathing, due to mechanical limitation to inflation and deflation, results necessarily in hyperpnœa in the sense of increased alveolar ventilation, but it is probable that it can be a factor in the production of subjective discomfort or dyspnœa

The higher centres can also affect the respiratory centre The voluntary control of respiratory movements is evidence of this, and it is probable that the tachypnœa seen in hysteria and in emotional states is of a similar nature In addition to the afferent stimuli from the lungs there may well be influences on the centre through the nervous system from other parts of the body The immediate cessation of the respiratory movements on plunging into cold water is suggestive of a reflex from the skin, but there is no clear evidence of the paths of these reflexes if they do exist

In the last few years a considerable number of observations have been made in various countries in an endeavour to elucidate the mechanism of the dyspnœas seen in cases of heart failure With the help of my colleagues, G Graham, C F Harris, D'Arcy Prendergast, R Hilton, and G C Linder, a number of observations have been made on patients with cardiac disease in the past three or four years and I propose next to discuss these results, to compare them with the results of other observers, and to discuss their bearing on the solution of the problem of cardiac dyspnœas These observations have a bearing on the causes of hyperpnœa, and consist of examinations of arterial blood For work of this nature, involving the quantitative estimation of blood gases and of blood reactions, several observers, working as a team, are necessary The persons constituting the team have had unavoidably to be changed from time to time, but the work of the team has been consecutive, and I have the permission of my colleagues to utilise the results in this discussion

A group of cases of heart failure accompanying mitral stenosis and auricular fibrillation were investigated because such cases show marked dyspnœa as a rule, and because this condition is seen in younger patients, so that it is possible to obtain a state of heart failure uncomplicated by lung disease, such as chronic bronchitis and emphysema, or by the vascular and renal changes so common in older patients In addition groups of cases of heart failure with high blood pressure and arterial disease, and with asthma or chronic bronchitis and emphysema, have been studied

Oxygen Saturation of Arterial Blood

The group of cases with mitral stenosis and auricular fibrillation consisted of eight patients, all of whom had severe dyspnœa on admission The observations were frequently not made until a few days after admission, when some degree of recovery had occurred, but all had marked dyspnœa and orthopnœa at the time All but one had râles at the bases of the lungs and some œdema there, though slight In some cases second or third observations were made during recovery, and in two instances observations were made on second admissions for recurrence of heart failure The blood was obtained by puncture of the femoral artery, and the oxygen capacities and saturations were estimated by the Haldane apparatus for blood-gas analysis

The results are shown in Table II The saturation of the arterial blood with oxygen in health should not be lower than about 95 per cent One case only had a value clearly lower than this, No 5 It is of interest, further, to note that at the second observation on this patient, at a time when he seemed somewhat improved in general condition, the oxygen saturation was still lower than on the first occasion The dyspnœa, cyanosis, and œdema were not more marked in this patient than in several of the others, but he was peculiar in that there was *friction* at both bases on admission, and that on the occasion of the second observation he was complaining of acute pain in the right side of the chest, where fine friction was audible It is probable, therefore, that in addition to heart failure this patient had an inflammatory lesion in the lungs, or possibly an infarct All the others showed normal saturation, both during the stage of severe failure and, in the cases where second observations were made, in the stage of recovery or improvement. Case 2 is of special interest, because the attack of heart failure was acute and of short duration and because the second observation was made after the auricular fibrillation had ceased and normal cardiac mechanism been restored by the use of quinidine The observations on Case 3 are peculiarly valuable, because they extend over a period of two years and because of the extreme degree of failure and of dyspnœa at the time of the fourth observation. At the time of the first observation on Case 4 a severe degree of digitalis intoxication was present and was the cause of the increased failure that necessitated admission to hospital

Sl = Slight

The group of cases with high blood pressure and arterial disease consists of six patients There was no evidence of endocarditis in any of them They were on the whole considerably older than those of the first group Cyanosis was not so obvious, and the dyspnœa tended to occur in attacks, but dyspnœa and orthopnœa were present in all at the time of the arterial puncture In two instances the Cheyne-Stokes type of periodic breathing was seen The results are shown in Table III In this group also the absence of unsaturation of the arterial blood is the striking feature Case 9 had œdema of the legs and ascites, a right bundle-branch lesion, and numerous ventricular extrasystoles The systolic blood pressure was 166 mm of Hg and the diastolic 120 mm The condition had commenced to improve at the time of the first observation The second observation was made during a paroxysmal attack of dyspnœa, and the oxygen saturation was the same as before There was a striking fall in the oxygen capacity and hæmoglobin content of the blood, but this was probably due to the onset of erysipelas that became manifest next day, and from which he died nine days later Case 10 was very similar, but had Cheyne-Stokes breathing a day or two before the first observation At the time of the second observation he was much worse and was unconscious. There was then distinct cyanosis, and an oxygen saturation of only 91 per cent He died a few hours later Case 11 had chronic gout, a right bundle-branch lesion, and blood pressure of 174 mm systolic and 116 mm diastolic There was no œdema, but orthopnœa was constant This patient was liable to attacks of severe nocturnal dyspnœa, when cyanosis appeared with diffuse râles in the lungs and blood-stained sputum. Case 12 had a blood pressure of 291 mm systolic and 170 diastolic There was some œdema of the legs and albuminuric retinitis The blood-urea was only 0 055 per cent At the time of the first observation there was pronounced Cheyne-Stokes breathing, and the arterial blood was drawn during a period of hyperpnœa At the second observation the condition had improved, there was till a periodicity in the respiratory rhythm, but there were no

definite apnœic pauses. At the third observation the condition was greatly improved, the breathing had lost all periodicity, but orthopnœa was still present. Case 13 is important, as it showed marked oxygen unsaturation. This was the only case in the group that showed cyanosis comparable in degree with that of the cases of mitral stenosis and auricular fibrillation in the first group. The cyanosis was of a more leaden hue than in the cases of the first group The blood pressure was 234 mm systolic and 150 mm diastolic Generalised œdema was pronounced, and there was ascites and fluid in the pleural cavities At the time of the first observation improvement had commenced and was well marked by the time of the second observation. When the third observation was made the patient had commenced to get up; there was no obvious œdema nor ascites. There were still some râles at the bases of the lungs It is of importance to note that at the second observation, when the patient's general condition was greatly improved and the dyspnœa, œdema, and cyanosis were less, the oxygen saturation of the arterial blood had not increased Case 14, who also showed a definite oxygen unsaturation, had œdema of the legs and râles at the bases of the lungs There was marked orthopnœa and definite cyanosis The blood pressure was 262 mm systolic and 152 mm diastolic Severe exacerbations of dyspnœa occurred from time to time, and six weeks after the arterial blood was examined the patient died in uræmia Autopsy showed chronic interstitial nephritis At the time of the observation on the arteria blood the blood-urea was 0 060 per cent, and the patient's condition was essentially one of heart failure.

The third group comprises three cases in which definite pulmonary disease was present in addition to heart failure The results of the estimation of the oxygen content of the arterial blood are shown in the first part of Table IV. Case 15 had aortic regurgitation and a greatly hypertrophied and dilated heart There was a history of bronchial asthma extending over many years, and pronounced emphysema was present The observations extend over two periods of admission to hospital On both occasions at the first observation on the arterial blood severe orthopnœa was present There was œdema of legs and back and râles at the bases of the lungs On all occasions the oxygen saturation of the arterial blood was within normal limits Case 16 had a long history of bronchitis and of bronchial asthma The blood pressure was 180 mm systolic and 92 mm diastolic, and the heart was hypertrophied and the arteries hard Orthopnœa was present and there were râles at the bases of the lungs and rhonchi all over There was slight cyanosis and œdema of the back and legs The patient was commencing to improve when the arterial blood was examined, and the oxygen saturation was at the lower limit of the normal. Case 17 was that of a man, aged 35, with severe chronic bronchitis and emphysema The right side of the heart was enlarged and the fingers clubbed Cyanosis and orthopnœa were marked The lower thorax was sucked in with each inspiration, and râles and rhonchi were numerous over both lungs In this case the oxygen saturation was definitely low.

TABLE IV

Oxygen saturation of arterial blood in three cases of chronic pulmonary disease with heart failure, and in two cases of heart failure not included in other groups All had dyspnœa and orthopnœa

A p = Angina pectoris

In Table IV. are included two cases that do not fall into any of the above groups Case 18 had aortitis and aortic regurgitation, probably syphilitic in origin, and suffered from attacks of angina pectoris The arterial blood was taken during an attack when there was orthopnœa, a clammy sweat, and distinct cyanosis There were râles at the bases of the lungs, and the respiratory movements were irregular, apparently from involuntary interference The oxygen saturation was normal Case 19 was that of a frail woman, with carcinoma of the uterus and considerable emaciation There were numerous ventricular extrasystoles, a few râles at the bases of the lungs, and slight orthopnœa There was no apparent cyanosis and the oxygen saturation was definitely reduced.

These results point to the absence of a consistently low oxygen saturation in the dyspnœa of heart failure In general the saturation is within normal limits, and it would appear that it is in exceptional cases only that a low saturation is seen The cases in this series in which a low saturation was found are of interest Cases 5 and 17 had evidence of pulmonary disease in addition to heart failure Case 19 had carcinoma of the uterus, and the patient was in a feeble dying condition At the time of the second observation on Case 10 the patient was unconscious and died a few hours later Case 13 recovered, but on admission was in an extremely critical condition, with severe congestive failure and a considerable amount of fluid in the pleural cavities Case 14 did not appear so seriously ill on admission as Case 13, but did not respond to treatment, and died in uræmia of chronic interstitial nephritis a few weeks later

The results of other observers are in general agreement with these observations Harrop,[18] Barach and Woodwell,[19] Campbell, Hunt, and Poulton,[20] Peters and Barr,[21] and Meakins, Dautrebande, and Fetter [22] have published their observations and these have been collected and discussed by Meakins and Davies [2] They conclude that unless there are obvious pulmonary disturbances present as a result of the heart failure the oxygen saturation of the arterial blood is within normal limits The results in this series hardly justify such a conclusion, but any criticism must depend on the meaning of the word "obvious." We endeavoured, when possible, to select cases that had little evidence of pulmonary involvement, but all had obvious respiratory distress when at rest in bed, and with few exceptions there were râles at the bases of the lungs at the time of observation Of the cases with mitral stenosis and auricular fibrillation Case 6 alone was without pulmonary râles In the second group Cases 9, 11, and 12 were free of basal râles The results recorded by Eppinger, Papp, and Schwarz [23] are in agreement with the observations in this series, and it would appear that some notice must be taken of the cardiac lesion accompanying the heart failure In cases of mitral stenosis a degree of œdema of the bases of the lungs that can be recognised clinically may be present without oxygen deficiency in the arterial blood, but in heart failure due to myocardial degeneration, pulmonary congestion, and œdema are usually accompanied by oxygen deficiency.

Cyanosis —Lundsgaard and Van Slyke [24] have discussed the factors responsible for cyanosis, and have pointed out that two factors may be present in heart failure—peripheral stasis and deficient oxygenation of the blood in the lungs They suggest also that distension of capillaries and an increase in the number of open capillaries may be contributing factors They point out that in mitral valve disease cyanosis may appear at an earlier stage of failure than in other types of heart disease A comparison of the results shown in Tables II and III shows agreement with this, and justifies the conclusion that while cyanosis is pronounced in cases of mitral stenosis, even when there is no deficient oxygenation of the arterial blood, in cases of myocardial degeneration cyanosis is only pronounced when failure is advanced, lung involvement severe, and deficient oxygenation of the arterial blood present Case 2 is exceptional in that only slight cyanosis was noted, even when dyspnœa was severe It is possible that a definite aortic regurgitation, which was present in addition to mitral stenosis, may account for the peculiarity in this instance.

It is justifiable to conclude, therefore, that oxygen deficiency in the arterial blood or deficient oxygenation of the blood in the lungs is not present with any consistency in cases of cardiac dyspnœa It is found when (*a*) pulmonary disease is present in addition to heart failure, (*b*) in the presence of gross congestion and œdema of the lungs, and (*c*) in feeble or dying patients

It is conceivable that the normal oxygen saturations are the result of increased ventilation, and that the increased ventilation is primarily due to a deficiency in the oxygenation of the arterial blood If a deficiency were primarily causal the percentage saturations in the presence of severe dyspnœa would be at best about the lower limits of the normal But this is not so In most instances the figures are well within the normal limits Further, it is difficult to support the view that arterial oxygen deficiency is a cause of the dyspnœa in Case 13 in which a lower saturation was found at the second observation when the patient was greatly improved in general condition and the dyspnœa was markedly less than at the time of the first observation That it is only because of the hyperpnœa that the oxygen saturations are maintained within normal limits is probable Morphia, 1/8 gr, was administered hypodermically in Case 15, and an examination of the arterial blood drawn half an hour later showed a drop in the oxygen saturation from 100 to 80 per cent, accompanied by a cessation of the distress and of the exaggerated respiratory movements

If, then, there is a cause of the hyperpnœa and dyspnœa of heart failure common to all cases, it cannot be deficient oxygenation of the blood in the lungs

Lettsomian Lecture

ON THE

SURGERY OF THE SPINAL CORD AND ITS MEMBRANES.

Being the Second Lettsomian Lecture in 1927, delivered before the Medical Society of London on March 9th, 1927,*

BY DONALD ARMOUR, C M G, M B TORONTO,
F R C S ENG, M R C.P. LOND,
SENIOR SURGEON TO THE WEST LONDON HOSPITAL AND SURGEON TO THE NATIONAL HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM

IN 1908 Spiller read a paper before the College of Physicians of Philadelphia entitled Circumscribed Serous Spinal Meningitis, a Little Recognised Condition Amenable to Surgical Treatment In 1903 a case had been reported by Spiller, Musser, and Martin, in which an exploration for a tumour had revealed only a cystic condition— a delicate pial cyst"— of the meninges Beyond doubting its possible parasitic origin, no suggestion was made as to its ætiology or pathogenesis

In his paper Spiller said .—

> "Almost nothing is known as to the origin of apparently idiopathic collections of fluid within the pia-arachnoid The fluid may be from the blood-vessels of the pia, and the mesh-like structure of the leptomeninges may predispose to adhesions, but why these cysts occur in any given case, especially where there are no evidences of inflammation, we do not know The symptoms are those of circumscribed compression of the spinal cord, and the condition cannot be distinguished clinically from tumour of the cord"

Since then an increasing interest has been shown in this condition, under many different designations, all descriptive of the local condition usually found, but none attempting to explain its ætiology or pathogeny "Serous spinal meningitis" (Oppenheim), "localised hydrops of the meninges" (Schlesinger), "arachnitis adhæsiva circumscripta" (Krause), "chronic spinal meningitis" (Horsley), "arachnoïdite cloisonnée" (Bouché) "meningitis serosa und serofibrosa" (Gerstmann)—such are the various names used for a condition associated pathologically with the presence of adhesions between the spinal theca and the arachnoid, with consequent damming up under pressure or with localised cyst formation, of the cerebro-spinal fluid, and evidenced clinically by the symptom-complex of a medullary compression

MENINGITIS SEROSA CIRCUMSCRIPTA

Although the earliest description of this condition is attributed usually to Schlesinger, who, in 1898, described the post-mortem findings of a case of cord compression due to a localised hydrops of the meninges, it had been doubtless recognised long before this date For there was published in Bonn in 1840 a thesis by one P Schmitz entitled "De meningitide spinali quam vocant circumscriptam" I regret that a search of the libraries of London, Edinburgh, and Cambridge has been unproductive, and therefore, I cannot give you further details of his article. But the title clearly indicates that his subject must have borne a close relationship to the one I am now presenting.

I think it will simplify matters if I exclude at once certain conditions, which, while often associated with a circumscribed serous meningitis, do not form any part of my subject

1 —*Extradural processes* —(1) Infective or inflammatory disease of the vertebral column—e g, Pott's disease, acute or chronic osteomyelitis, syphilis, typhoid spine, actinomycosis (2) Extradural tumours

2 *Intradural processes* —(1) Intradural extramedullary tumours (2) Intramedullary tumours

The condition I am dealing with is characterised clinically by the progressive evolution of a compression paraplegia, and pathologically by meningeal adhesions, varying from fine discrete strands of translucent membrane, arising from the arachnoid and passing across the space between the dura and the cord, to adherent processes more or less completely surrounding the cord, either fixing the latter or dragging it laterally, and matting the roots The cerebro-spinal fluid may be held up by a transverse partition formed by these processes, or retained in cyst formations of varying size. While the circumscribed location of the lesion gives to it its characteristic clinical picture, the adhesions and proliferation of the arachnoid are more or less diffuse, both above and below the neurological level, but the process remains harmless unless it produces compression of the cord

Reference should be made to a similar pathological condition affecting the posterior fossa of the skull not as yet commonly recognised While some cases are undoubtedly due to an infective process arising from otitis media, many others have an obscure ætiological origin These cases may simulate cerebellar or cervico-medullary tumour. Horrax describes this condition as "cisternal arachnoiditis" The localisation of this process to the posterior fossa may even account for cases of hydrocephalus of obscure origin.

---

* The first Lettsomian Lecture appeared in THE LANCET of Feb 26th, 1927.

The Spinal Arachnoid Membrane

Let me here recall a few points in the anatomy of the spinal arachnoid membrane The arachnoid is a thin delicate non-vascular areolar tissue membrane lying outside the pia and connected with it by slender filaments of trabecular connective tissue Above, it is continuous with the cerebral arachnoid, and on either side it is continued on the various spinal nerves to form a sheath for them The outer surface of the arachnoid is in contact with the inner surface of the dura, both of which are lined by a layer of endothelial cells The interval between them, merely a potential space, constitutes the subdural space and contains a small amount of fluid of the nature of lymph The subdural and subarachnoid spaces nowhere connect with one another The inner surface of the arachnoid is separated from the pia by a considerable interval, which is called the subarachnoid space This space is largest at the lowest part of the spinal canal where it encloses the nerves forming the cauda equina

Superiorly, it is continuous with the cranial subarachnoid space, and is brought into communication with the general ventricular cavity of the brain by means of the openings in the pia mater in the roof of the fourth ventricle The spinal subarachnoid space is filled by cerebro-spinal fluid sufficient in amount to expand the arachnoid membrane, so as to completely fill up the whole of the space included in the dura mater The subarachnoid space is occupied by subarachnoid tissue, trabeculæ of delicate connective tissue, connecting the pia mater with the arachnoid, and, in addition, is partially subdivided by a longitudinal membranous partition, the septum posticum, which connects the pia and arachnoid opposite the posterior median fissure This partition is incomplete and cribriform in structure, formed by interlacing bundles of white fibrous tissue The space is also partially divided on either side into an anterior and posterior compartment by the ligamenta denticulata

In structure the arachnoid membrane consists of distinct riband-like bundles of fine fibrous tissue, interlaced into one another, for the most part running in a longitudinal direction Several layers of this tissue, arranged in a complex way, constitute the arachnoid membrane proper The subarachnoid trabeculæ consist of fine fibrillar tissue, each of which is surrounded by a delicate nucleated sheath The whole constitutes a typical areolar connective tissue, interrupted at numerous points and covered by a continuous layer of endothelial cells The subarachnoid space contains numerous blood-vessels some of which are free and others attached to the arachnoid Their adventitia is covered by endothelium, hence the subarachnoid space would seem to assume the character of a perivascular space

Reactions of Membranes to Injury.

Let us now consider what are the reactions to injury, mechanical or chemical, of the membranes of the cord, as throwing light upon the formation of the adhesions so characteristic of the condition of meningitis serosa circumscripta Very valuable and suggestive experimental work has been done on this subject by Sayad, Lear, and Harvey working together They first investigated the reaction of the dura to injury with an uninjured arachnoid, and, secondly, the reaction of the injured arachnoid with an uninjured dura. The former experiment consisted in removing a circular piece of the dura through a trephine opening in the temporal region, every care being taken to avoid injuring the pia arachnoid lying beneath it They found that the operative defect is filled at once by blood-clot, which on its inner face is lightly adherent to the arachnoid and on its outer intimately adherent to the exposed temporal muscle The process of organisation of the clot begins at once and takes place in much the same way as elsewhere in the body There is an immediate invasion of phagocytes, followed almost at once by wandering and polyblastic cells and then in time by fibroblasts These all appear to come in large part from the overlying temporal muscle and to be evenly distributed throughout the clot Those reaching the inner surface adjacent to the arachnoid membrane become arranged in a plane tangential to that surface and very soon there is a distinct skeletal arrangement of the cells corresponding to the architecture of the dura A little later certain of these cells are arranging themselves along the inner face of the blood-clot in contact with the arachnoid, forming a limiting membrane resembling the endothelial lining of the normal dura Sayad and Harvey think that it is highly probable that the endothelial or endothelial-like lining seen at this early period is derived from cells coming from the muscle side of the clot and not by an ingrowth of endothelium from the cut edge of the dura This surface becomes complete at the end of a week and at this time the clot loses its fibrinous adhesions to the arachnoid From this time on the process is largely one of growth and condensation of connective tissue behind the lining cells

It is apparent, therefore, that healing of the dural defect takes place without the ingrowth of any fibroblasts into the arachnoid, so essential for the formation of adhesions This impregnability of the arachnoid surface to the reaction of repair in the dura prevents the formation of adhesions, and acts as a mould for the reconstruction of the dura.

As a corollary, it is of interest to see what happens in the healing of an injury to the arachnoid when the site of its injury is covered by normal dura Lear and Harvey investigated this problem in a series of experiments A dural flap was turned down with strict precautions against injuring the inner surface of the dura and the arachnoid The pia arachnoid, well away from the line of dural incision, was subjected to a small sharply localised area of injury As a result, it was found that where there was an injury to the pia-arachnoid, even though the overlying dura was uninjured, dense adhesions between all three layers of the meninges were formed These adhesions formed early, became denser with time, and persisted In order to exclude the possibility of the dural reaction being due to blood between it and the arachnoid, experiments were conducted in which blood was left between the dura and uninjured arachnoid As might be expected, no adhesions were formed In other words, blood in the presence of an intact arachnoid does not produce adhesions Hence, a necessary premise to the formation of adhesions between the dura and arachnoid is injury to the latter, and the essential point would appear to be an injury to the outer cells of the arachnoid Over the spinal cord, where the pia and arachnoid are widely separated from each other, such injury would probably not involve the pia, which might well act as another limiting membrane Over the cerebral cortex, on the other hand, any reparative process in the arachnoid will probably stimulate a similar reaction in the pia, and, if sufficiently severe, in the cortex itself

Why do the dura and arachnoid react in such different fashions when healing? Lear and Harvey suggest as an explanation, and they receive support from Clarke and from Lewis, that the dura is not lined with true endothelium, but rather by cells which have undergone a certain metaplasia from mesoblatic elements, in order to serve the same purpose The lining cells of the dura, therefore, are less stable and enter readily into any adjacent inflammatory reaction The lining cells of the arachnoid, however, are more highly differentiated than those of the dura and are, therefore, more stable in character Thus it is that the inner surface of the dura does not act as a limiting membrane in the presence of an attempted repair in the underlying arachnoid, but, on the contrary, enters intimately into the process, with the result that the arachnoid, when injured, becomes adherent to the dura, and healing takes place with adhesions between them

We may, I think, conclude from the foregoing findings, that in order to have adhesions it is not necessary to have any injury to the dura whatever, but that damage to the lining cells of the arachnoid alone will result in the formation of adhesions Moreover, the work of Esseck indicates that a relatively minor injury is sufficient to induce a cellular reaction in the interstices of the arachnoid Ayer has shown, too, that, if such reaction is intensified, the actual destruction of lining cells may take place both within the interstices and on the surface of the arachnoid sufficient to lead to cicatrisation and the formation of adhesions The application of what has gone before to our subject under discussion—viz, the pathogeny of meningitis serosa circumscripta, is this that injuries, sometimes exceedingly slight, minimal birth injuries, mild attacks of serous meningitis, even the meningeal reactions that occur at the onset of many infectious diseases, may of themselves be sufficient to cause enough damage to the arachnoid to lead to adhesions, which later in life may be of clinical importance

ÆTIOLOGY. MENINGITIS SEROSA CIRCUMSCRIPTA

I think there can be no question that previous infections of the meninges, either primary or secondary, may be followed by a serous meningitis Such undoubtedly occurs, as already mentioned, in the posterior fossa *secondary to otitis media* This would explain the diffuseness of the condition so often found in the cord. Nor is it difficult to imagine that, in a more or less mild diffuse condition, the brunt of the reaction may have fallen upon one particular section of the arachnoid more than another, giving rise to a circumscribed lesion, more severe than elsewhere and the only one to make its presence known clinically It may be remarked here that the majority of cases show a lower cervical or upper dorsal localisation. There is a patient now in the National Hospital in the service of Dr Walshe, and upon whom I have operated, whose symptoms followed five months after an attack of epidemic cerebro-spinal meningitis Oppenheim also refers to this as a cause Bouché reports a case following upon an attack of typhoid three years previously, during which the patient had had symptoms of a meningitis Horrax states with regard to serous meningitis localised in the posterior fossa that influenza and encephalitis are possible causes, there being evidence in favour of the latter Flatau, Jacobsohn, and Minor regard meningitis serosa circumscripta as a "chronic inflammatory condition," but do not commit themselves further. Horsley invoked syphilis and gonorrhœa as the chief ætiological factor I had the privilege of assisting him or of seeing the majority of his cases, and that they were not all cases of meningitis serosa circumscripta, as we now understand it, is clear from his own description. He describes a "shrunken cord, the seat of a sclerogliosis," and refers only in passing to meningeal adhesions Sachs and Glaser have classified their experiences of cases showing symptoms of a compression paraplegia with a definite sensory level, which were operated upon, as follows —

1 Those with normal looking cord and meninges
2 Those with normal cord but with pathological changes in the meninges.
3 Those with pathological cord and normal meninges
4 Those with pathological cord and meninges.

They describe the appearances of the cord in Group 3 as "small and white, with the vessels small and diminished in number," the so-called "cadaveric cord" Such was the condition in many of Horsley's cases Oppenheim thought too that at least in some of these cases, there is a combination of intramedullary lesion with the serous meningitis Bruns was strongly of the opinion that an idiopathic condition exists, apart from any disease of the spine, meninges, or cord itself

Traumatic Conditions.

The most important contributions concerning the ætiology of this disease in recent years refer to trauma as an ætiological factor The importance of this, especially from a medico-legal point of view, cannot be exaggerated. Although cases had been reported by Krause, Weisenberg, and Muller, Bruns and others, in which a history of trauma had been obtained, it was not considered of any importance as a causative factor, and Horsley rejected it altogether Muller, of Marburg, refers also to the operative trauma incident to the successful removal of spinal tumours as a cause of meningitis serosa circumscripta coming on slowly but progressively some years afterwards

When one considers head injuries, in which so often localised adhesions of the meninges occur as an after-result, it is not difficult to conceive a like result occurring in the spinal canal following upon trauma Gerstmann, in reporting six cases and describing them fully, rejects infection and primary disease of the spinal cord as ætiological factors, and regards trauma as the most common one He maintains that a torsion or jarring of the vertebral column may cause a slight damage to the meninges, with resulting adhesions, which tend to be progressive in character Probably the most important contribution to the subject is that of Mauss and Kruger They found in 54 laminectomies for war wounds, 23 cases of meningitis serosa *circumscripta* In all the origin was undoubtedly traumatic In 14 there was direct injury to the spine, but in the remaining nine the injury was remote from the spine. In these cases they are of opinion that a commotion of the spinal column with its protected spinal cord, whether due to direct impact upon the spine or transmitted thereto through other parts of the skeleton is *the* ætiological factor. They suggest also that a mere traction of the plexuses may be a sufficient cause They are of opinion that in the majority of cases the intradural process is not inflammatory, as such histological investigations as were carried out showed no evidence of such a process in the strands of arachnoid They suggest, however, that the process begins as a pachymeningitis or peripachymeningitis following upon a peridural hæmorrhage If we are to accept the conclusions formulated by Sayad, Lear, and Harvey, this alone would be insufficient and we most postulate damage to the cells of the arachnoid as well However produced, we must, I think, regard trauma as a very important ætiological factor in the production of the disease

Although offering no new evidence as to the ætiology of the condition, Stookey would explain the mechanism causing the disturbances in the cord as follows With each respiratory excursion there is a dorsoventral movement of the spinal cord *throughout* its length of approximately 5 mm in each direction, greater in the cervical and upper dorsal regions If adherent bands are present, the cord is fixed at the points of attachment, while above and below it moves normally. Thus with each respiration angulation at the fixed segment occurs, which when constant and continued over a long period of time induces disturbances in cord conduction He extends this theory to explain the more frequent occurrence of the localising lesion in the cervical and upper dorsal regions, where the respiratory excursions of the cord are greatest He suggests also that, owing to the interference with the normal mobility of the cord by meningitis serosa circumscripta, slight injuries may be productive of a greater degree of traumatism to it than would have otherwise been the case This is a very fascinating theory but one which is obviously open to severe criticism

Age and Duration

Meningitis serosa circumscripta occurs most frequently in the fifth and sixth decades of life, but as Bruns had a case 16 years of age and my oldest was a man of 70 it obviously may occur at any age in *adult life*

Though Stookey lays great stress upon the duration of the disease as a factor in differential diagnosis—50 per cent of his cases having had a course of more than nine years—it is possible. however, to attach too much importance to the time element Three of my own cases were of four, six, and nine months respectively, though another was of nine years' duration It may be said in general terms that the onset of the disease is usually slow and its development protracted.

SYMPTOMATOLOGY

In general terms it may be said that the symptoms of meningitis serosa circumscripta are those of an extramedullary spinal tumour. But there are certain differences which make it possible to suspect or even to diagnose the former condition One of these is the variability of the symptoms observed on examination at short intervals, which is the most characteristic feature of the clinical picture. This concerns pain, motor, sensory and sympathetic irritation phenomena, and the reflexes

Unilaterality of symptoms marks the disease in its early stages On the sensory side subjective symptoms predominate Pains, paræsthesiæ, and hyperæsthesia are prominent symptoms Pain is widespread, diffuse, and indeterminate in distribution, not localised, and referred to distant skin areas Hyperæsthesia is generally extended to a whole limb, with "band" sensations at ankle, knee, abdomen, or neck A uniradicular zone of hyperæsthesia at the upper level of the lesion is very rare The pain and hyperæsthesia may be very intense and disabling apart from any loss of power Sensory loss is often not complete and may present variable limits from day to day It affects all modes of cutaneous sensibility equally in degree and extent Stookey found marked involvement of vibratory and muscle, joint and tendon sense, with dissociation at times of these two varieties A Brown-Séquard syndrome is frequently seen in this condition, and is characterised by slowness of progression and its almost daily variability. Further, also, by the fact that the sensory changes in the upper zones are more profound than those in distal zones For example, one may find a complete loss over the trunk, while in the lower limbs only a partial loss may be present This is a point that Collier has frequently emphasised.

On examination motor disturbances are more marked in most instances than sensory. Weakness of limbs at first limited to one side, then later involving the other, followed by paraplegia, or even quadraplegia Irritative motor phenomena, multiradicular in type, may be present In Mauss and Kruger's cases many showed a tendency to spontaneous or readily elicited reflex movements, a source of great discomfort to the patients, especially at night Widespread twitching and fibrillation of muscles within the affected area also occurred. Contrary to Horsley and other observers, they found vasomotor, secretory, and trophic disturbances fairly common These included hypothermia, cyanosis, redness, swelling, hyperidrosis, hyperkeratosis, and anomalies of the nails Disturbances of bladder and rectum are either absent or occur rather late in the evolution of the disease. Dysuria and urgency of micturition are more characteristic than incontinence, which, when present, tends to be transient

Mauss and Kruger report in cervical lesions, the sudden appearance of bulbar symptoms, dyspnœa, nystagmus, facial palsy, and limitation of head movements, all of which they regard as the strongest indications for operation, and which were permanently abolished thereby Vertebral tenderness has been found in some cases, but when present bore no definite relation to the level of the lesion

The Cerebro-spinal Fluid.

The cerebro-spinal fluid in meningitis serosa circumscripta varies as it does in spinal tumour, depending upon the completeness of the block The absence of any increase in the protein content and of xanthochromia cannot be invoked, as Stookey claims, to differentiate this condition from spinal tumour He says. "A prolonged history, a positive cerebro-spinal fluid manometer result, and a normal total protein content are the most important points in the differential diagnosis from spinal cord tumour" Analysis of the cases reported in the literature show that many had an increased protein content, varying from "slight" to "marked"

Cases of my own vary from a normal protein content to 0 15 per cent, and two had xanthochromia and one showed coagulation. My colleague, Sargent, has had cases showing a variation from normal to 0·2 per cent, two with xanthochromia, and one showed a coagulum. Sicard and Laplante report an increase of protein even as high as 0 55 per cent, while Bouché speaks of a "marked" increase in one of his cases.

Differential Diagnosis

The conditions from which it is most difficult to diagnose meningitis serosa circumscripta are syringomyelia and intra- and extra-medullary tumour Syringomyelia may be excluded by the presence of a true dissociated anæsthesia, joint affections, and vertebral deformities Intramedullary tumours show a difference in levels for temperature and pain, and tend to show an upward progression of the sensory level Also the saddle area—i e, that supplied by the lower sacral segments—frequently shows a relatively slight sensory disturbance An extramedullary or root tumour is characterised by the localised severe root pain associated with complete loss over that segment and a stationary upper level In circumscribed meningitis the profoundness and character of the sensory disturbance at the upper level are more widespread than in spinal tumour Further, the pain frequently affects more than one root and may be bilateral, thus giving the diffuse character to the pain referred to so often by various observers Cases may show a broad band of hypoæsthesia over the trunk, while in the legs no sensory disturbance is to be made out Yet a change in the reflex activity points to interference with the spinal tracts The condition may be differentiated from plexus lesions by the fact that the symptomatology in the latter condition can be explained by a purely extraspinal lesion—in other words, there is a complete absence of pyramidal tract involvement and bladder disturbance

In general terms it may be said that the most outstanding features in meningitis serosa circumscripta are the variability of the symptoms, the diffuseness of the pain, and the preponderance of subjective sensory over motor phenomena in the initial stage of the disease, while at a later stage the motor disturbances are more easily demonstrated than the sensory As previously shown, examination of the cerebro-spinal fluid gives no assistance in diagnosis owing to the variability of the findings

TREATMENT.

The treatment of meningitis serosa circumscripta is purely surgical The aim of the operation is the division and removal of the proliferated and adherent arachnoid, the freeing of the roots and the cord within the theca, and the re-establishment of a free cerebro-spinal fluid circulation The more definitely localised the lesion the more easily and the more completely can these results be attained Failure to secure complete success is due probably to the widespread nature of the condition One is not dealing therefore with a meningitis serosa circumscripta but with a meningitis serosa diffusa Unfortunately, there is no means of differentiating between these two types prior to operation.

The indications for operation are the same as for spinal tumour—viz, stationary symptoms not improved by other treatment, or progressive symptoms, in either case where a definite level has been established An immediate operation may be called for in cervical cases with the onset of bulbar symptoms The operative findings are always the same within the fairly wide limits of the pathological process The theca is distended and shows no pulsation The cerebro-spinal fluid is always under tension and on opening the dura either it escapes in a strong stream or its egress is interrupted by the *œdematous* arachnoid protruding into the incision in the form of a violet-grey shiny cyst On the escape of the fluid pulsation usually returns, and this must be regarded as strong presumptive evidence of the absence of a tumour. On widely opening the arachnoid localised cyst formation may be found with evidence of pressure on the cord, the roots may be encased in thickened arachnoid dragging upon and distorting the cord laterally, or the subarachnoid space may be completely obliterated at the site of the lesion.

Contrary to my own experience Mauss and Krüger describe a remarkable vascularity of the membranous processes. I have frequently seen tortuosity and engorgement of the veins and pallor of the cord, both suggestive of venous obstruction and interference with the vascular supply of the cord. The freeing of the cord and removal of the adherent processes produce at once a return to more normal vascular appearances, with disappearance of the venous distension and reappearance of the normal colour. Whatever the condition, it is dealt with *secundum artem* throughout the length of the operative exposure. It is well not to suture the dura on closing the wound with a view to preventing the formation of new adhesions. The muscles are closed in layers by interrupted catgut sutures.

The results of operations are in some cases brilliantly successful. The more localised the condition and the earlier the stage of the proliferative process the better chance of this result. Symptoms, even in cases primarily cured, may return in after years from a progression of the process at or about the same level or at one remote from it. Such has been my experience in one case. The widely diffuse process, involving the greater part of the cord or the cord at different and remote levels, is beyond the reach of operative approach.

CARBOHYDRATE TOLERANCE IN OVER-WEIGHT AND OBESITY.

By R. S ALLISON, M.D. Belf., M.R C P. Lond,
PHYSICIAN, RUTHIN CASTLE.

THE following observations are based on a survey of 121 cases of overweight and obesity collected from the records of Duff House, Banff, and Ruthin Castle. In ascertaining the degree of overweight of a subject, reference has been made to tables[1] giving the average weights for all ages and heights. It is admitted that there must be considerable latitude of opinion as to what constitutes an average weight, and, whereas reliance has been more or less arbitrarily placed on these tables, yet no case which was only slightly above the average was included, but only those which were distinct, and who themselves, knowing what their average weight was, had admitted their obese condition and presented themselves for treatment for this cause alone, or on account of the glycosuria which in a few cases accompanied it. In this series the degree of overweight varied from 14 lb. to as much as 130 lb. above the average.

In the use of the terms overweight and obesity no difference other than one of degree is intended. Strouse and Dye,[2] however, draw a distinction between the terms, reserving overweight for those cases which result from overfeeding and sedentary habits. Obesity, though often the sequel of the same causes, in their view, may also arise in some instances without any excessive food intake or lessened expenditure of energy.

The cases in this series were all adults, 80 being within the age period of 40–60. In childhood and adolescence obesity is often associated with dysfunction of the endocrine glands, particularly the pituitary, and the same may be true to a lesser extent in adult life, when obesity is more frequently the result of extrinsic causes, such as overeating, combined with lack of adequate exercise. The scope of this paper is directed towards this class, so far as possible, cases of pituitary disease being excluded by clinical and laboratory means and by X ray examination of the skull. It is, of course, recognised that in many cases it is difficult to separate the exogenous types of obesity from the endogenous.

Occurrence of Glycosuria.—Sugar was present in the urine of 17 cases out of the 121, the amount varying from a trace to 22 g in the 24 hours. Acidosis, as judged by the presence of acetone and diacetic acid in the urine, was absent in almost all, and when present was found in traces only. These cases were regarded clinically as mild diabetics. The remaining 104 showed no outward sign of a diabetic tendency.

Sugar-tolerance Tests.

The majority were treated before the blood-sugar curve was introduced as a means of testing carbohydrate tolerance. In 20 recent cases, however, such tests have been carried out. The technique employed was as follows: 60 g. of powdered cane sugar were given by the mouth at 9 A.M. on a fasting stomach, the last meal being about 7.30 on the preceding night. 0.2 c.cm. of blood was obtained by pricking the finger, before taking the sugar and at frequent intervals for three hours after. The bladder was emptied before the test and again at one, two, and three hours after. For the blood-sugar estimations the method of MacLean was used.

Before proceeding to the consideration of abnormal results, it would be well to enunciate what normal, or standard, they are to be compared with MacLean and de Wesselow[3, 4] place the maximum rise of blood-sugar in health, after the ingestion of 50 g. of glucose, at 0 16–0 18 per cent, and require it to have returned to normal in one and a half hours In infancy and up to the age of 3 years as shown by Spence,[5] the blood-sugar rises but slightly after a dose of sugar, and there is evidence to show that sugar tolerance decreases with advance of years R Hale-White and W W. Payne[6] conclude that the fasting blood-sugar level lies below 0 12 per cent for all ages They point out that over the age of 70 the maximum rise in health may be up to 0 22 per cent, and suggest that for subjects under 30 the time taken to regain the fasting level should be extended *to two hours and for those over 30 to three* hours C D. Shapland,[7] using 60 g of cane sugar, has found, in considering sugar-tolerance tests from ten healthy adults aged 20–40, that starting from a fasting level of 0 12 per cent a maximum of 0 16–0 20 per cent was obtained, a fair average being 0 17 per cent, and thereafter the resting level was regained in one and a *half hours* *In ten healthy adults aged* 50–60 he found the average fasting level to be 0 13 per cent, the maximum blood-sugar 0 21 per cent, and the fall to resting level delayed to two hours

For the purposes of this paper, a maximum rise of blood-sugar to 0 18 per cent will be taken to represent the normal In the accompanying diagrams of the results of sugar-tolerance tests on obese subjects, blood-sugar figures above this are shaded in black, to indicate clearly the area of hyperglycæmia in each case and to serve in comparing them with each other The main features of the 20 cases are summarised in the tables shown. They are divided into two groups, group A, consisting of 12 cases of simple obesity whose daily urine was normal, and group B, consisting of 8 cases of obesity complicated by glycosuria—i.e, mild diabetics

GROUP A —*12 Cases Simple Obesity*

Case	Sex and age	Duration of obesity	Degree of over-weight	Daily urine	After ingestion 60 g sugar			
					Fasting blood-sugar	Max rise of B S	Return to fasting level in	Urine during test
		yrs	lbs		%	%	hrs	
a	F 35	4	+62	N	0 11	0 16	1½	N
b	M 65	8	+75	"	0 11	0 18	1½	"

t	F 43	20	+36	22 g sug in 24 hrs	0 22	0 36	Over 3	"

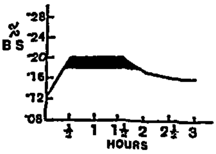
Sugar Tolerance —Cases *a* to *e*, normal, *f*, *g*, slightly decreased, *h* to *n*, moderately decreased, *o* to *t*, much decreased. N, normal Tr sug, trace sugar

Features of Sugar-tolerance Tests in Groups A and B

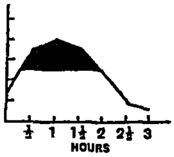
(A) *Simple Obesity* —Sugar was found in the urine of three cases only of the 12 during the test The fasting blood-sugar level was above 0 12 per cent in nine cases, the maximum height above 0 20 per cent in six, and the return to fasting level delayed to two and a half hours or more in seven

Five of the cases showed a normal sugar tolerance, whereas of the remaining seven, two displayed a slight departure from the normal and five a moderate hyperglycæmia, evidence of decreased sugar tolerance This is graphically represented in the diagrams Figs 1, 2, 3, 4, 5, the shaded areas indicating the extent of the hyperglycæmia

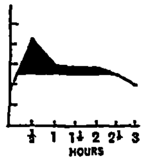
1

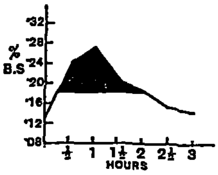


2

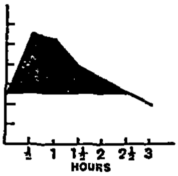


3

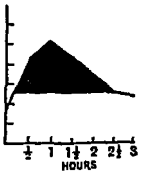




4



5



6

(B) *Obesity and Glycosuria* —Abundant sugar occurred in the urine of all subjects during the test From the table again, the fasting blood-sugar is seen to be above 0 12 per cent in six cases, the maximum height above 0 20 per cent in all eight, and the return to fasting level delayed to over three hours in six out of eight There is less discrepancy between the individual members of this group than in the previous group A Here not a proportion but all display a definite diabetic type Fig 6, representing a composite curve of the eight cases, is of the diabetic type, as shown by the extensive shaded area of hyperglycæmia provoked by the dose of sugar

These results may now be summarised —

Type	Fasting level of blood-sugar	Maximum rise after 60 g sugar	Return to fasting level in	Urine during test
Normal	0 09–0 12 %	0 17–0 20 %	2 hr	Normal
Obesity (Group A) (12 cases)	Above 0 12 % in 9 out of 12	Above 0 20 % in 6 out of 12	Delayed to 2½ hr or more in *7 out of 12*	Contained sugar in 3 out of 12
Obese *diabetic* (Group B) (8 cases)	Above 0 12 % *in 6 out* of 8	Above 0 20 % *in all*	Delayed to *2½ hr or* more in all	Contained *sugar in* all

Bearing of Results on Relation of Obesity to Diabetes

The association *of obesity and* diabetes is well known Diabetics frequently give a *history of over*-weight preceding the onset of the disease. In an *analysis of 1063 cases of* diabetes, Joslin[8] states that obesity preceded the onset in 40 per cent Root and Miles[9] place the percentage lower, at 20 per cent In this series, examination of the urine showed glycosuria in but 14 per cent *or 17 out of 121 cases* The position in relation *to* diabetes of the remaining 104 remains in doubt until sugar-tolerance tests are applied.

Sugar tolerance in adolescent cases of pituitary disease displaying obesity has been studied by Gardiner-Hill, Jones, and *Forest-Smith*[10] These workers found in the early stage *of the condition* a decrease of carbohydrate *tolerance*, in the later an increase The variety of obesity under discussion here—i e, that of adult life arising from extrinsic causes—is very worthy of consideration, as it is undoubtedly this type which is associated with the development of diabetes It is only, therefore, what might be expected, when in many cases sugar-tolerance tests reveal a well marked diabetic tendency or decreased ability to deal with carbohydrate. No hard-and-fast rule need be drawn between what is a normal and what is an abnormal curve If the 20 cases on which sugar tolerance tests were performed, are placed in the order of the degree of hyperglycæmia, they are seen to pass by gradual stages from the undoubtedly normal to the as surely diabetic type Labbé and Boulin[11], giving 50 g of glucose to obese subjects, have demonstrated similar results and supported the view long held that a certain proportion of the obese are in danger of becoming diabetic

From a survey of the varying results obtained by examination of the 20 cases, it is obvious that the diabetic tendency is not present in every case, and varies in degree when it is present It is likely, therefore, that there are factors at work which render one case more likely to develop diabetes than another These may now be discussed

Possible Factors Disposing to a Diabetic Tendency in the Obese

1 *Effect of Reduction of Weight on Sugar Tolerance* —It is a general observation that in diabetic subjects who are over weight, reduction of weight, even if only of a few pounds, leads to improvement of sugar tolerance. This is, of course, the foundation of the fasting treatment of diabetes, the reduction of food sparing the pancreas If the decreased sugar tolerance shown by many of the above cases is in any way connected with their obesity, a similar result should follow reduction of their weight In Case *h* (Fig 7), whose weight was 17 st 2 lb in 1925, a sugar-tolerance test gave a curve tending to the diabetic type Under dietetic treatment weight was reduced to 13 st 13 lb (loss of 3 st approximately) A sugar-tolerance test was again performed nine months later under the same conditions and by the same observers, and gave a normal type of curve (Figs 7 and 8) This could not be due to immediate effects of the diet, and it would seem that, in this case, permanent reduction of weight had benefited sugar tolerance In another case seen since, and not included in the above, reduction of weight resulted in improved tolerance It seems reasonable to suppose, therefore, that the obesity is directly connected with the decreased sugar tolerance shown by many of these cases

2 *Degree of Overweight* —Joslin[8] has said that diabetes is the penalty of obesity, and that the greater the obesity the more likely is nature to enforce it It seems indeed likely that the greater the degree of overweight the more would the sugar-tolerance test show a departure from the normal The experience in this series is not, however, in agreement with this view. There appears to be no relationship between the extent of the obesity and diabetic tendency If the sugar-tolerance curves of the 20 cases are placed in their ascending order of overweight, no corresponding uniform decrease in sugar tolerance is seen One case, 110 lb over average weight, showed only a slight departure from the normal, whereas another, 55 lb over the average (Case *k*, Fig 3), shows a diabetic type of curve

3 *Age* —The effect of age on sugar tolerance has already been referred to, and on this ground it might well be argued that the type of curve seen in the obesity of middle life may not be due to the obesity, but to the age of the patient Figs 1, 2, 3, 4, 5 are curves which cannot be explained on grounds of age alone Furthermore, the workers above mentioned[6] have not stated whether their subjects were over weight or not, but merely that they were healthy individuals

4 *Hypertension and Hyperglycæmia* —Mohler[12] describes cases in middle life showing the syndrome of hypertension, hyperglycæmia, obesity, and arteriosclerosis, obesity being said to favour the development of arterio-sclerosis and high blood pressure In only three of the 20 cases was the systolic blood pressure above 160 mm. of mercury, so that the question whether high blood pressure and not obesity has to do with decreased sugar tolerance does not arise in this series.

5 *Duration of Obesity.*—Referring back to the tables, groups A and B, the duration of the obesity is stated for each case In nine it is under 10 years and in 11 cases of 10 years' duration or more It is interesting to compare the results of sugar-tolerance tests for these two periods of time —

Sugar tolerance	Under ten years' duration (9 cases)	Ten years' duration or over (11 cases)
Normal	4	1
Slightly decreased	1	1
Moderately decreased	4	9

The periods of time stated are, of course, approximate only, and the total number of cases small to draw conclusions from, but the relatively large number of diabetic curves obtained from cases of obesity of long-standing is noteworthy

More evidence is found in Case *m* (Fig 6). This patient was first admitted to Duff House in 1916 His weight then was 16 st, height 6 ft There was a trace of sugar in the urine In 1921 a sugar-tolerance test gave the result shown in Fig. 9 He was then passing 2 g sugar in the 24 hours No serious effort was made on the part of the patient to reduce weight which fluctuated between 16 and 17 st, until readmission in 1926, when he was found to be passing 58 g. of sugar in the 24 hours on the same diet as in 1921. A sugar-tolerance test was repeated and gave the results shown in Fig. 10 It is obvious that a considerable further decrease in sugar tolerance has taken place since 1921, and this cannot be attributed entirely to his increase of age from 54 to 60 It would seem reasonable to suppose, therefore, that it is the length of time the obesity has continued unchecked which influences the tendency to diabetes It is of interest to note that the French observers already mentioned favour this view.

Ætiology of Decreased Sugar Tolerance in Obesity

If we admit that many cases of obesity, particularly those of long standing, display a decreased carbohydrate tolerance, it remains to discuss the possible genesis of the condition In the normal adult, the body-weight undergoes but slight fluctuation; the process of anabolism, resulting from the intake of foodstuffs more or less balancing catabolism from the expenditure of energy.

In the type of obese subject under consideration, conditions favouring excessive anabolism and interference with this balance are present The simplest example is that of the person who lives too well and takes inadequate exercise This process once begun will continue, for the more abundant and rich the food the less will be the desire for physical exercise Further, the stouter and more spherical the subject, the less food per kilogramme is required for body purposes A time will come when the individual limit of storage is reached, and then, or in all probability before then, the storage mechanism will default, giving rise to excessive accumulation of sugar in the blood, with leakage into the urine This stage is represented by the "fat" diabetes class The quantity of sugar in the urine of these cases was never great, and urine rarely showed indications of the incomplete combustion of fat in the presence of acetone bodies It would, therefore, seem likely that the internal pancreatic secretion of these cases was not greatly affected

During the years of gradual increase of weight the pancreas has been called upon to deal with excessive amounts of carbohydrate As shown by Allen,[13] a condition of hyperglycæmia is detrimental to the internal secretory tissue of the pancreas As a result some deterioration of the insulin secretion might be expected Individual susceptibility may explain why a few cases proceed to a further stage with rapid wasting and signs of severe diabetes The majority of obese subjects, however, apparently remain at this stage, revealing their diabetic tendency only when examined by sugar-tolerance tests A small number pass to the "fat" diabetes type and a few only to severe diabetes

Summary

1 The above observations are based on a survey of 121 cases of obesity, occurring in adult life and arising from extrinsic causes, such as overeating, lack of adequate exercise, or a combination of both. So far as possible cases of endocrine disturbance have been excluded

2 An attempt has been made to study carbohydrate tolerance in this type of obesity and to inquire into the relationship which is known to exist between obesity and diabetes

3. Glycosuria was present in 17 cases only, or in 14 per cent The remaining 104 were sugar free, and showed no outward sign of a diabetic tendency.

4 Sugar-tolerance tests were performed in 20 instances, including eight of those who were known to have glycosuria From a review of these it would appear that, though some individuals much over weight have a normal sugar tolerance, many display a partial inability to deal with carbohydrate, and especially those who are known to have glycosuria

5 In those who show decreased sugar tolerance, an improvement in tolerance, or even a return to normal, may take place if weight is reduced

6 There is evidence to prove that the decreased carbohydrate tolerance is dependent on the length of time the obesity has existed unchecked

In conclusion I desire to express my sincere thanks to Dr E I Spriggs for much valuable help and criticism and to my colleagues, A J. Leigh, J S Jeffery, and T J. Dobie, by whom the blood-sugar estimations were carried out in the Ruthin Castle laboratories

REMOVAL OF THE METATARSAL HEAD

FOR HALLUX VALGUS AND HALLUX RIGIDUS *

BY GEORGE PERKINS, M CH OXF, F R C S ENG,
ASSISTANT SURGEON TO THE ROYAL NATIONAL ORTHOPÆDIC HOSPITAL, ORTHOPÆDIC REGISTRAR, ST THOMAS'S HOSPITAL

I HAVE recently examined more than 50 patients operated upon for hallux valgus or hallux rigidus in the orthopædic department at St Thomas's Hospital during the five-year period 1921 to 1925

The operation is a standard one A straight dorsal skin incision is used The head of the metatarsal is excised at the level of the neck, thus removing half an inch or more of the bone A plain vertical surface of raw bone is left; protruding spikes of bone are removed, and the edges are bevelled The phalanx is not touched. The sesamoids are left intact, and no tendons are interfered with As a rule the bursa is not dissected out and removed No material is interposed between the raw end of the matatarsal and the phalanx No splint is used afterwards Ten days after the operation the stitches are taken out, and the patient gets up in a large sized shoe He is treated daily for a week or so with faradic foot baths, and is fitted either with an anterior arch support, or else with a platform made of felt or sponge rubber, running from the heel to just behind the heads of the metatarsals

Results

From the patient's point of view—The results of this operation, as of many surgical procedures, are judged differently by the patient and by the surgeon. The vast majority of patients are immensely pleased Only two out of the 50 were doubtful whether they had derived any benefit Most of the patients before the operation were prevented from working owing to pain All of them are now at work of varying kinds, as shopmen, policemen, porters, domestic servants, gardeners, &c They one and all declared that there was no longer any pain in the big toe joint. Some, however, complained of pain in the other toes and under the outer side of the forepart of the foot A few remarked that they could not get the big toe on the ground, although they did not complain about it

From the surgeon's point of view the results are as follows · In every patient the severe valgus deformity had disappeared, the big toe might deviate slightly towards the other toes but in most cases it was straight The big toe was usually shorter than the second toe after the operation and possibly this was a factor in retaining the big toe in its straight position. The bunion always disappeared as a result of the operation, and this happened in spite of the fact that the bursa was rarely ever touched at the time of the operation. As regards the position of the big toe, in 75 per cent. of patients there was a slight amount of permanent dorsiflexion so that the big toe did not come down on to the ground The average range of movement was 15 degrees Although there was no relationship between the amount of power in the big toe and the amount of movement, the arc of movement did seem to influence, if the big toe was permanently dorsiflexed the power was feeble, while if the big toe touched the ground there was always considerable power My impression is that the best arc of movement is from 5 degrees of plantar flexion to 10 degrees of dorsiflexion, 10 degrees of dorsiflexion seemed ample for every purpose of/the big toe Our custom has been to bandage the big toe into dorsiflexion after operation to ensure that it should be dorsiflexed, in my opinion it would be better to aim for a straight position The range of movement, whether small or large, was invariably painless

* A paper read before the British Orthopædic Association.

Cause and Relief of Metatarsalgia

A certain number of patients complained of pain in the other toes or under the heads of the metatarsals Unfortunately, owing to insufficient data, I do not know how many of these patients were suffering from metatarsalgia prior to the operation Judging from observations on recent cases not included in this review, I should estimate the number at 50 per cent

Although metatarsalgia is popularly supposed to be due to a dropping of the anterior arch, I find myself in sympathy with those surgeons who attach little importance to the anterior arch Certain it is that a flat anterior arch may be symptomless In my opinion, metatarsalgia and a flat anterior arch are associated, because with a flat anterior arch there often is a fixed dorsiflexion of the metatarso-phalangeal joints of the toes, and it is the limitation of plantar flexion at these joints that causes the metatarsalgia A brief explanation will make this clear When a person takes a step forward, his leg muscles have to lift the body off the ground and propel it forward This can be done in two ways If the ankle, tarsal, and metatarso-phalangeal joints are held stiff, the calf muscles (particularly the toe flexors) supply the power and the fulcrum is formed by the toes pressing down on the ground If the metatarso-phalangeal joints cannot be held stiff or are dorsiflexed, the toes can no longer act as the fulcrum of the movement and the fulcrum is shifted back to the heads of the metatarsals The heads of the metatarsals are not intended by nature to act as a fulcrum for the propulsion of the body, and if they are so used, there results the formation of callosities on the skin under the heads of the metatarsals and an irritative arthritis of the metatarso-phalangeal joints—the syndrome known as metatarsalgia By the term "metatarsalgia" I do not refer to the pathological condition associated with the name of Morton I employ it as a useful, indefinite term, in the literal sense—viz, pain in the neighbourhood of the metatarsals

The essence of the treatment of metatarsalgia consists in restoring the fulcrum from the heads of the metatarsals to the toes, and hence one's aim is to increase the range of passive plantar flexion at the metatarso-phalangeal joints by manipulations and to improve the power of active plantar flexion by strengthening the plantar flexors On this hypothesis the metatarsalgia existing prior to the operation is due to lack of toe plantar flexion, and the operation renders the condition worse because it often abolishes the power of plantar flexion of the big toe-joint

The review of the results of the operation for hallux valgus supports this hypothesis In patients with toes that were either clawed or rigid, metatarsalgia was the rule, in some of these the wearing of an anterior arch support, a concealed metatarsal bar, or a felt platform relieves the symptoms In patients with straight and mobile toes the support could be, and often was, dispensed with The less the big toe was dorsiflexed, the greater was the power in the big toe and the less frequent was the metatarsalgia

Considering that metatarsalgia is often present with hallux valgus or rigidus, it would seem advisable to treat the condition at the same time as the valgus; and I would suggest that as a routine before the patient leaves the operating table the inter-phalangeal joints should be forcibly straightened, and the metatarso-phalangeal joints should be forcibly plantar flexed—after tenotomy of the extensor tendons if necessary—and maintained in that position by means of a slab of plaster-of-Paris which could be removed on the tenth day when the stitches are taken out Then the masseuse will take care to preserve the power of plantar flexion at the metatarso-phalangeal joints and to strengthen the interossei muscles by faradism and exercises

Age in Relation to Operation

The age of the patients operated upon varied between 16 and 71 The most successful operations were those done on patients below the age of 20 Six patients under that age were operated on; one plays tennis and walks any distance, the second walks 20 miles a day, one is a domestic servant on her feet all day long, another is a salesman in a shop from 8 A M to 6 P M, and the sixth goes in for sprint races and has won prizes for long distance running This is contrary to the usual belief that operations during the growing period are inadvisable, and certainly for this reason these patients would not have been operated upon unless their symptoms had been severe and resistant to palliative measures Five suffered from hallux valgus and one from hallux rigidus Whether the operation is done for rigidus or for valgus does not seem to affect prognosis

Summary

To sum up, the operation of excision of the head of the metatarsal can be relied on always and completely to cure symptoms due to hallux valgus and to hallux rigidus It does not relieve metatarsalgia—in fact, it often makes it worse And it is suggested that the existing metatarsalgia should be treated at the time of the operation by straightening the toes and plantar-flexing the metatarso-phalangeal joints, and that further metatarsalgia be avoided by ensuring that the arc of movement of the big toe after the operation is the ideal one—i e, from 5 degrees of plantar flexion to 10 degrees of dorsiflexion

FOUR CASES OF SPONTANEOUS SUBARACHNOID HÆMORRHAGE.

By HUGH BARBER, M D, M R C P LOND,
HONORARY PHYSICIAN, DERBYSHIRE ROYAL INFIRMARY,
AND
H. C. C TAYLOR, M.B, B S LOND,
HOUSE PHYSICIAN TO THE INFIRMARY

IT is difficult sometimes to decide whether a disease is occurring more frequently or whether it is being recognised more commonly During six months four cases of spontaneous subarachnoid hæmorrhage were admitted to the Derbyshire Royal Infirmary. The publication of several recent papers has encouraged us to put this series on record

The Clinical Picture

The signs and symptoms on admission have conformed to a typical text-book description[1] The clinical picture has been that of cerebral compression and meningeal irritation combined, sometimes the one and sometimes the other preponderating, very similar to a case of meningitis where drowsiness, tending towards coma, is associated with irritability on examination. The symptoms of headache, vomiting, *stiffness of the neck*, and some rigidity of the limbs have been present in every case. But the temperature has been *normal in the first day* or two and the onset quite sudden, as one would expect in a vascular lesion Case 1 was in bed with headache and stiff neck 15 days before admission, but developed a sudden collapse with loss of consciousness after getting out of bed The others were prostrated as rapidly as a case of apoplexy No cranial nerve palsies were observed, but some degree of retinal change was present in two cases, the most striking one showed very definite hæmorrhages Lumbar puncture in all four cases revealed cerebro-spinal fluid under pressure which was deeply coloured with blood When allowed to settle there was some coloration in the *upper part* of the fluid, showing that the blood was not an accidental contamination No organisms *could be obtained* When coma was pronounced lumbar puncture relieved the condition, and all four patients made steady but variable progress towards recovery After a further rest in bed they were discharged without any *serious* symptoms remaining Glycosuria was not present;

but the two elderly patients had albuminuria, which cleared up eventually Herpes zoster has been described in this condition,[2] but was not present in our cases.

Diagnosis.

The diagnosis is suggested by the sudden onset of the symptoms of cerebral compression associated with irritability on examination and other signs of meningeal irritation such as headache and neck rigidity. In one of our patients (Case 1) there would appear to have been some oozing, leading to neck rigidity, some days before free hæmorrhage occurred. The blood-stained cerebro-spinal fluid is quite characteristic, showing after standing a tinted supernatant fluid. In all our cases it was obvious and quite typical when taken immediately or a few days after the onset of the symptoms. Cerebro-spinal fluid withdrawn later on showed excess of leucocytes without red cells, which might have suggested meningitis if the earlier lumbar puncture had been omitted. Collier[4] points out that this is explained by the fact that the red cells have disintegrated and the leucocytes have remained, he states that a differential count will demonstrate that the cells are in the same proportion as in a count of the blood Some pyrexia may be present as in all cases of hæmorrhage into a serous cavity, but it develops after the onset in contrast to meningitis

Although herpes facialis is common in meningitis, herpes zoster does not occur, and Adie regards this latter, if present, as a valuable aid in the diagnosis of subarachnoid hæmorrhage [2] A large and rapidly fatal subarachnoid hæmorrhage is indistinguishable from a cerebral hæmorrhage which has ruptured into the ventricles; but this type of case is of pathological rather than clinical interest

Prognosis

From our own cases, all of whom recovered, and others recently recorded, the immediate prognosis would appear to be fairly favourable Six months after the illness three of our patients have resumed their normal life, with occasional headache in the two elder ones Case 4 did not have so long a rest in bed, and although getting about has not progressed so well Symonds says the attacks tend to recur, and quotes a case of recovery in which two previous attacks had been diagnosed as meningitis [1] The recording and following up of such cases as ours should furnish knowledge from this point of view

Ætiology

Hæmorrhage into the subarachnoid space in such conditions as diseases of the blood and infective endocarditis does not concern us In spontaneous cases, two underlying pathological conditions have been found Hæmorrhage may occur as the result of atheroma of the cerebral arteries, but in many cases it comes from the rupture of a congenital aneurysm which is not easy to demonstrate but is not uncommon around the circle of Willis [1] Our own cases, judged by their age, would suggest that two were due to congenital aneurysm and two to atheroma Symonds says syphilis is not a common cause Three of our patients were tested with negative Wassermann result The exciting cause of an attack might come up for discussion in a case of compensation, but it would not appear that any severe effort or injury is needed when the underlying pathological condition is present One of our cases was attributed by the patient's wife to a vigorous blowing of the nose

Treatment

Rest in bed, prolonged for some weeks after symptoms have subsided, is the main indication We did not use any drugs in our cases Lumbar puncture is indicated for increasing signs of compression and relieves the symptoms and danger On the contrary, where cerebral irritation is severe, it is difficult to perform and might do harm; moreover, some amount of increased pressure may tend to stop the bleeding.

Notes of the Cases.

Case 1 —L W., female, aged 52 years Nov 13th, 1925. Sudden severe frontal headache with stiffness of neck—patient was dazed and her speech thick—symptoms improved in bed and she got up on the 25th. Headache returned on the 28th, and patient collapsed in lavatory, she was picked up unconscious

On admission to Derbyshire Royal Infirmary she was comatose Temperature 97° F, pulse 47, very collapsed, two hours later she was drowsy, very irritable, with rigidity of neck, and vomiting frequently, pupils equal, regular, and reacted sluggishly to light, no paralyses, slight optic neuritis with several large hæmorrhages on the fundus, heart and lungs normal, blood pressure (systolic) 150 mm Hg, urine contained albumin, no sugar Vomiting was frequent for 24 hours as consciousness gradually returned. Nov 30th. Perfectly intelligent, headache and neck rigidity still present Lumbar puncture yielded 25 c cm of fluid, which contained much blood but no micro-organisms From then onwards recovery appeared complete On Dec 7th the cerebro-spinal fluid contained 35 cells per c mm, which were mixed polymorphs and lymphocytes On Dec 21st it contained eight lymphocytes per c mm The Wassermann reaction was negative in blood and cerebro-spinal fluid

Sept 11th, 1926. Patient active and well, but complains of headache when she is overtired Mental condition is perfect

Case 2 —S B, female, aged 59 years March 17th, 1926. Sudden frontal headache with gradual loss of consciousness.

On admission to the infirmary ten hours later she was comatose, with neck rigidity and Kernig's sign positive on both sides Temperature 97° F, pulse 80 The pupils were equal, regular, and reacted sluggishly to light, the plantar reflexes were both flexor Heart and lungs normal, urine contained albumin, optic discs normal March 19th Drowsy, irritable, and complained of frontal headache; neck still rigid and occasional vomiting On lumbar puncture 30 c cm of deeply blood-stained fluid was withdrawn, containing no micro-organisms April 10th Full consciousness and muscular power returned gradually, neck rigidity being the last sign to disappear

Sept 9th Patient well and getting about, still has occasional lapses of memory and frontal headache

Case 3 —E S, male, aged 13 years Jan 3rd, 1926 Sudden occipital headache while walking in street, walked 100 yards home and lay down He never lost consciousness, headache was severe and continuous, and vomiting frequent for 36 hours

On admission to the infirmary on Jan 6th patient was drowsy and irritable and complained of violent pain in the back of his head Temperature 99 4° F, pulse 60, neck rigid and head retracted, Kernig's sign positive on both sides, no other signs in nervous system Heart and lungs, optic discs, and urine normal On lumbar puncture 35 c.cm of blood-stained fluid were withdrawn, with temporary relief of headache Examination of the fluid for organisms was negative To relieve the headache, which was very severe, lumbar puncture was repeated daily for five days, and thereafter less frequently The blood gradually disappeared from the cerebro-spinal fluid, and on the 30th normal fluid was obtained with a cell count of four lymphocytes per c mm Recovery appeared complete, the headache lasting for some days after the neck rigidity had cleared up

Sept 9th. Patient feels perfectly fit, is doing light work, and has had no return of headache Mental condition normal, no physical signs in heart, chest, or nervous system; optic discs normal Systolic blood pressure 130 mm Hg, blood Wassermann reaction negative

Case 4 —A S, male, aged 33 years May 16th, 1926 Complained of sudden slight pain in neck while taking a meal, half an hour later, on blowing his nose, fell unconscious He recovered consciousness partly in a few hours, and remained drowsy, vomiting frequently, and shouting with pain in his forehead for three days

On admission to the infirmary on May 20th patient was drowsy and irritable, and complained of frontal headache Temperature 99 4° F, pulse 76 Neck rigid, Kernig's sign positive, and extensor plantar responses on both sides; pupils normal; no signs in chest and heart, urine normal slight optic neuritis Lumbar puncture yielded 8 c cm of blood-stained fluid not under pressure, examination of the fluid for organisms was negative Full consciousness returned gradually without further vomiting May 22nd. Headache still severe On lumbar puncture 25 c cm of blood-stained fluid were withdrawn under pressure Headache relieved and did not return Recovery apparently complete, the neck rigidity disappearing last Blood Wassermann reaction negative

Sept 9th Patient still has occipital headache brought on by exertion, and has not returned to work No physical signs in heart, lungs, or nervous system; optic discs normal systolic blood pressure 185 mm. Hg.

We are indebted to Dr. A. D. Hunt for permission to publish Case 8.

Clinical and Laboratory Notes.

A CASE OF MUMPS ENCEPHALITIS.

BY HARRY BEDINGFIELD, D.S.O., M.B., CH.B. EDIN., M.R.C.P. LOND.

REPORTS of mumps encephalitis are sufficiently rare to justify the publication of the following case.

On Dec. 23rd, 1925, a previously healthy boy, aged 5 years, while Christmas shopping with his mother, complained of the sudden onset of pain in his legs sufficiently severe to prevent him from walking and necessitating his immediate return home by taxi-cab. He was seen by me an hour later and found to have a temperature 104° F, pulse-rate 80, and respirations 25. His right knee was slightly swollen, and both knees and tibiæ painful and tender. There were no other physical signs to be detected. On the 24th temperature was normal, and the swelling of the knee had disappeared but he complained of tenderness of the extensor thigh muscles. No further physical signs had appeared, yet the child looked ill, was somewhat dull mentally, and refused food. In the evening, with a rise in temperature, all pain disappeared. On Christmas Day his condition was the same until the afternoon when I was hurriedly called to see him as he was said to have "collapsed." I found him with a barely perceptible pulse, feeble respiration, and semi-comatose, only answering after repeated questioning. Two hours later this state had completely passed. On the 26th his condition remained the same, "collapsing" each afternoon and rallying in the evening. From the onset of his illness he was obstinately constipated, refused all food, and vomited any nourishment that was forced upon him. A blood-count revealed a leucocytosis of 12,000 with polymorphonuclears 85 per cent. On the morning of the 28th he was so severely collapsed that the parents believed him to be dead, but he rallied in about an hour. He then complained of pain and tenderness in the epigastrium. For the first time a few rhonchi and scattered crepitations appeared in both lower lobes of his lungs. In the afternoon I found him presenting a most striking picture. Propped up in bed as if intensely dyspnœic, he had an area of intense pallor around his nose and mouth, with a deeply flushed face and neck. The epigastrium was firmly retracted and there were no respiratory movements of his lower ribs. Examination of his chest revealed a definite early broncho-pneumonia of the left lower lobe with respirations 40. The whole appearance of the child was that of being in intense pain although complaining of none. Dr. C. W. Vining saw the boy in consultation with me and neither of us could suggest an explanation of his condition. It was decided to give him a hypodermic injection of morphine (gr. 1/12) and await events. Three hours later the child was quite unconscious, lying on his side, head retracted, both arms rigidly extended at the shoulders, pronated and flexed at the wrists and fingers, both lower limbs were hyperextended, and his feet plantar flexed. Two hours later Dr. Vining saw him again with me when the rigidity had passed off sufficiently to perform a lumbar puncture. There was no increase in the pressure of cerebro-spinal fluid which was perfectly clear. The child appeared to be so seriously ill that we concurred in giving the gravest prognosis. He was given a full dose of anti-pneumococcal serum in the belief that he was suffering from a pneumococcal septicæmia. On the 29th the child was still alive. Extensor spasm had completely passed and he lay curled up as if in a state of cerebral irritation with a relaxed open mouth and widely dilated pupils which still reacted to a strong light. Ophthalmoscopic examination showed dilatation of the retinal veins, no tendon reflexes could be elicited, and there was a positive Babinski. The abdomen was protuberant and reflexes absent. There was incontinence of urine and fæces. Notwithstanding skilled nursing, reddening of pressure points appeared with extreme rapidity, and the skin round the lumbar puncture began to slough. Unfortunately, the pathologist reported that the cerebro-spinal fluid had been contaminated by blood but he was of opinion that there was an intense lymphocytosis present. A blood-count, however, showed the polymorphonuclear leucocytosis was still present. On the 30th his condition was much the same, except for paresis of his right external rectus and the development of a distressingly frequent cerebral cry. On the 31st he suddenly regained consciousness at 7 A.M. and feebly asked for something to eat. However he immediately relapsed and did not regain consciousness again until 11 A.M. I saw him shortly after and he was then lying on his back with a Parkinsonian face and a pronounced external paresis of his eye muscle. I concluded he was suffering from encephalitis lethargica. He regained control of his bowel but had passed no urine since the night before, and his bladder was empty. On Jan. 1st, 1926, he still had anuria. Myoclonic movements appeared in his neck, extensor thigh, and abdominal muscles. On the 2nd he took some food and passed urine for the first time for 72 hours. In the evening both parotids became swollen, and a septic parotitis was diagnosed. On the 3rd myoclonus and paresis of his rectus had passed away, but the child now seemed to be gravely ill with broncho-pneumonia. On the 4th I was called to see a neighbour's boy whom I found to be suffering from mumps. I was then informed that the child had been in contact with no other child but my patient a fortnight previously. I now suspected that the case I am reporting was one of mumps with cerebral symptoms appearing before the parotid swelling. From the 2nd to 10th his chest condition slowly improved. On the 11th parotids began to subside and by the 16th the chest was clear. The child was well except for the extreme weakness of having passed through a severe illness. He has been seen by me at intervals. Over a year has now elapsed without the development of any sequelæ. The boy is a healthy robust child, normal in all respects both mentally and physically, which seems to rule out any possibility of his attack being one of encephalitis lethargica.

Although the first recorded case of cerebral manifestations in mumps is said to have been reported in England by Hamilton, there has been little attention paid to this aspect of the disease in English medical literature. Maximovitch, who reported the first post-mortem examination of a case dying from cerebral manifestations, found œdema of the brain surface, the sulci filled with a semi-fibrinous exudate, and hyperæmia of the pons and spinal cord. Lannois and Lemoine were the first to suggest that the cerebral manifestations were due to a true meningo-encephalitis. Acker, in 1913, was able to collect 30 fatal cases up to that time and reported two of his own in both of which he found a meningo-encephalitis at the base of the brain. During the war numerous reported cases were published by Haden, Casparis, Howard, and Larkin from the American armies, and by Michelean, Fiessinger, de Massary, and Sainton from the French. In all these reported cases the cerebral manifestations appeared after the parotitis. I can only find one case in the literature where they appeared before—namely, that reported by Colomb and Mercier of a soldier who was found comatose in his barrack-room with dilated pupils, stiff neck, and a positive Kernig sign. He remained in coma for three days, after which his temperature and pulse-rate fell and a double parotitis appeared. In the other cases where cerebral symptoms have been reported prior to the parotitis, these symptoms have been so slight or of such short duration that they could be well explained by the pyrexia. In none of them did they last longer than a few hours.

but the two elderly patients had albuminuria, which cleared up eventually Herpes zoster has been described in this condition,[2] but was not present in our cases.

Diagnosis.

The diagnosis is suggested by the sudden onset of the symptoms of cerebral compression associated with irritability on examination and other signs of meningeal irritation such as headache and neck rigidity. In one of our patients (Case 1) there would appear to have been some oozing, leading to neck rigidity, some days before free hæmorrhage occurred The blood-stained cerebro-spinal fluid is quite characteristic, showing after standing a tinted supernatant fluid In all our cases it was obvious and quite typical when taken immediately or a few days after the onset of the symptoms. Cerebro-spinal fluid withdrawn later on showed excess of leucocytes without red cells, which might have suggested meningitis if the earlier lumbar puncture had been omitted Collier[4] points out that this is explained by the fact that the red cells have disintegrated and the leucocytes have remained, he states that a differential count will demonstrate that the cells are in the same proportion as in a count of the blood Some pyrexia may be present as in all cases of hæmorrhage into a serous cavity, but it develops after the onset in contrast to meningitis

Although herpes facialis is common in meningitis, herpes zoster does not occur, and Adie regards this latter, if present, as a valuable aid in the diagnosis of subarachnoid hæmorrhage[2] A large and rapidly fatal subarachnoid hæmorrhage is indistinguishable from a cerebral hæmorrhage which has ruptured into the ventricles; but this type of case is of pathological rather than clinical interest

Prognosis

From our own cases, all of whom recovered, and others recently recorded, the immediate prognosis would appear to be fairly favourable Six months after the illness three of our patients have resumed their normal life, with occasional headache in the two elder ones Case 4 did not have so long a rest in bed, and although getting about has not progressed so well Symonds says the attacks tend to recur, and quotes a case of recovery in which two previous attacks had been diagnosed as meningitis[1] The recording and following up of such cases as ours should furnish knowledge from this point of view

Ætiology

Hæmorrhage into the subarachnoid space in such conditions as diseases of the blood and infective endocarditis does not concern us In spontaneous cases, two underlying pathological conditions have been found Hæmorrhage may occur as the result of atheroma of the cerebral arteries, but in many cases it comes from the rupture of a congenital aneurysm which is not easy to demonstrate but is not uncommon around the circle of Willis[1] Our own cases, judged by their age, would suggest that two were due to congenital aneurysm and two to atheroma Symonds says syphilis is not a common cause Three of our patients were tested with negative Wassermann result The exciting cause of an attack might come up for discussion in a case of compensation, but it would not appear that any severe effort or injury is needed when the underlying pathological condition is present One of our cases was attributed by the patient's wife to a vigorous blowing of the nose

Treatment

Rest in bed, prolonged for some weeks after symptoms have subsided, is the main indication We did not use any drugs in our cases Lumbar puncture is indicated for increasing signs of compression and relieves the symptoms and danger. On the contrary, where cerebral irritation is severe, it is difficult to perform and might do harm, moreover, some amount of increased pressure may tend to stop the bleeding.

Notes of the Cases.

CASE 1—L W, female, aged 52 years Nov 13th, 1925. Sudden severe frontal headache with stiffness of neck—patient was dazed and her speech thick—symptoms improved in bed and she got up on the 25th Headache returned on the 28th, and patient collapsed in lavatory, she was picked up unconscious

On admission to Derbyshire Royal Infirmary she was comatose Temperature 97° F, pulse 47, very collapsed, two hours later she was drowsy, very irritable, with rigidity of neck, and vomiting frequently, pupils equal, regular, and reacted sluggishly to light, no paralyses, slight optic neuritis with several large hæmorrhages on the fundus, heart and lungs normal, blood pressure (systolic) 150 mm Hg, urine contained albumin, no sugar Vomiting was frequent for 24 hours as consciousness gradually returned Nov 30th· Perfectly intelligent, headache and neck rigidity still present. Lumbar puncture yielded 25 c cm of fluid, which contained much blood but no micro-organisms From then onwards recovery appeared complete On Dec 7th the cerebro-spinal fluid contained 35 cells per c mm, which were mixed polymorphs and lymphocytes On Dec 21st it contained eight lymphocytes per c mm The Wassermann reaction was negative in blood and cerebro-spinal fluid

Sept 11th, 1926· Patient active and well, but complains of headache when she is overtired Mental condition is perfect

CASE 2—S B, female, aged 59 years March 17th, 1926 Sudden frontal headache with gradual loss of consciousness

On admission to the infirmary ten hours later she was comatose, with neck rigidity and Kernig's sign positive on both sides Temperature 97° F, pulse 80 The pupils were equal, regular, and reacted sluggishly to light, the plantar reflexes were both flexor Heart and lungs normal, urine contained albumin, optic discs normal March 19th Drowsy, irritable, and complained of frontal headache, neck still rigid and occasional vomiting On lumbar puncture 30 c cm of deeply blood-stained fluid was withdrawn, containing no micro-organisms April 10th Full consciousness and muscular power returned gradually, neck rigidity being the last sign to disappear

Sept. 9th Patient well and getting about, still has occasional lapses of memory and frontal headache

CASE 3—E S, male, aged 13 years Jan 3rd, 1926 Sudden occipital headache while walking in street, walked 100 yards home and lay down He never lost consciousness, headache was severe and continuous, and vomiting frequent for 36 hours

On admission to the infirmary on Jan 6th patient was drowsy and irritable and complained of violent pain in the back of his head Temperature 99 4° F, pulse 60, neck rigid and head retracted, Kernig's sign positive on both sides, no other signs in nervous system Heart and lungs, optic discs, and urine normal On lumbar puncture 35 c.cm. of blood-stained fluid were withdrawn, with temporary relief of headache Examination of the fluid for organisms was negative To relieve the headache, which was very severe, lumbar puncture was repeated daily for five days, and thereafter less frequently The blood gradually disappeared from the cerebro-spinal fluid, and on the 30th normal fluid was obtained with a cell count of four lymphocytes per c mm. Recovery appeared complete, the headache lasting for some days after the neck rigidity had cleared up

Sept 9th. Patient feels perfectly fit, is doing light work, and has had no return of headache Mental condition normal, no physical signs in heart, chest, or nervous system; optic discs normal Systolic blood pressure 130 mm Hg, blood Wassermann reaction negative

CASE 4—A S, male, aged 33 years May 16th, 1926 Complained of sudden slight pain in neck while taking a meal; half an hour later, on blowing his nose, fell unconscious He recovered consciousness partly in a few hours, and remained drowsy, vomiting frequently, and shouting with pain in his forehead for three days

On admission to the infirmary on May 20th patient was drowsy and irritable, and complained of frontal headache Temperature 99 4° F, pulse 76 Neck rigid, Kernig's sign positive, and extensor plantar responses on both sides, pupils normal; no signs in chest and heart, urine normal slight optic neuritis Lumbar puncture yielded 8 c cm of blood-stained fluid not under pressure, examination of the fluid for organisms was negative Full consciousness returned gradually without further vomiting May 22nd· Headache still severe On lumbar puncture 25 c cm of blood-stained fluid were withdrawn under pressure Headache relieved and did not return Recovery apparently complete, the neck rigidity disappearing last Blood Wassermann reaction negative

Sept 9th Patient still has occipital headache brought on by exertion, and has not returned to work No physical was made by Dr Peter Milligan, to whom we are indebted for careful observations

Post-mortem examination —The salient feature of this examination was early leptomeningitis at the base of the brain without any cerebral tumour (A detailed description of the right eye follows) In the thorax was found a large mediastinal growth extending far into the roots of both lungs, but deeper into the left Small metastases were scattered throughout both lungs Similar deposits were found also in the liver and in glands around the abdominal aorta

The right eye displayed invasion of the sclerotic on the nasal side of the eyeball, from optic nerve to margin of cornea, by growth averaging 4 mm in thickness One boss of growth was found external to the sclerotic The choroid on the nasal side of the eye was deeply invaded and to a lesser extent on the opposite side The retina was detached and pushed forwards all round the periphery of the eye except at one small area internal to the optic disc Sections of this eye showed carcinomatous growth of the same nature as that found in the left eye and in the mediastinal tumour, but of more vigorous mode of growth and with tendency to fusion of the carcinoma cells into syncytial masses

Microscopic examination of the mediastinal growth showed a slow-growing malignant tumour, the malignant cells very polymorphic, characterised by low proportion of cytoplasm and with distinctly acinar arrangement In a few areas the malignant cells were of "oat-cell" type, in other areas their appearance was highly suggestive of a bronchial origin, the columnar type of cell being evident Throughout the tumour there was much fibrous tissue formation and large areas showed necrosis of the carcinomatous elements

Pathological Condition

Carcinoma of the choroid rarely reaches the stage of being other than flat , here in both eyes the tumour had become quite large, filling up an important proportion of the vitreous space This had led to a condition of glaucoma, which is described as very uncommon in intra-ocular carcinoma C A Clapp [1] has found reports of 118 cases of metastatic carcinoma of the choroid and describes carcinoma of the lung as the second commonest prime focus for such metastases According to this author carcinoma occurs bilaterally in one-third of the cases, and more frequently in the left eye than the right The route of invasion of the eye is thought to be along lymph channels to the posterior part of the eyeball and then forwards by infiltration Our case appears to have conformed essentially to general experience

Examination of the left eye, removed during life, showed that the eyeball and surrounding tissues contained a solid growth which enclosed the optic nerve externally to the eyeball, forming a mass nearly 2 cm in diameter Within the eyeball the choroid was deeply and symmetrically invaded over the whole of the posterior part of its extent, the retina being correspondingly detached In this orbit the greater part of the growth lay external to the eyeball Sections of the growth showed a carcinoma described at first view as spheroidal-celled and highly malignant The prime focus of the carcinoma at this period was not clear, and a pancreatic origin was suggested purely on histological grounds The true origin was only determined after death

It may be said that the growth was increasingly malignant as it progressed from lung to left eye and then to right eye, but in all these structures a common origin could be traced The identity of the so-called "oat-celled sarcoma" of the mediastinum with carcinoma of bronchial origin has been recently discussed by W G Barnard [2] In his series of 19 cases of mediastinal tumour the age-incidence tended to be relatively low—27 years in one instance The age of our patient was 39 In mediastinal carcinomata this author has found great variation in the form of the constituent cells, and our experience with the metastatic growths in these eyes also exemplifies the pronounced differentiation of carcinoma cells whose prime origin was in bronchial columnar epithelium Barnard's series does not include any orbital metastases

Medical Societies.

ROYAL SOCIETY OF MEDICINE

SECTION OF ORTHOPÆDICS

A meeting of this Section was held on March 1st, Dr W T Gordon Pugh, the President, occupying the chair.

Mr A Rocyn-Jones read a paper on

The Treatment of Pes Cavus

He said that pes cavus (hollow foot) was the name given to a foot with an unusually high longitudinal arch Great variation in the relative heights of the arch was possible within normal limits, and often hollow foot of mild degree caused no trouble Cavus, however, was frequently associated with some other deformity Mr Rocyn-Jones dealt mainly with true or essential cavus

Ætiology.—Often the ætiology was not very clear, as the disability was not manifest until long after the exciting cause had disappeared But there were distinct contributory causes, which could be classified as follows (1) Postural, due to (*a*) faulty footwear, or (*b*) habit gait, compensatory for a short limb. (2) Paralytic, due to (*a*) acute specific fevers, including slight paralysis following rheumatism, scarlet fever, measles, and diphtheria , (*b*) infantile paralysis ; (*c*) chronic nervous disease, such as Friedreich's ataxy and progressive muscular atrophy , (*d*) congenital spinal cord lesions ; (*e*) external popliteal nerve injury. (3) Traumatic (*a*) foot injury, (*b*) racial custom—e g , Chinese foot

Mechanism of Deformity —The maintenance of the long arch of the foot, said Mr Rocyn-Jones, depended primarily upon the tone of the muscles Paralysis of the tendo Achillis would cause the heel to be drawn towards the toes by the plantar muscles, thus producing a cavus deformity, and the opposing dorsiflexors would tilt the foot upwards, but when these dorsiflexors were paralysed, an equinocavus deformity resulted Duchenne attributed pes cavus and the associated clawing of the toes to paralysis of the interossei and lumbrical muscles, this allowing the long and short extensors of the toes to overact by hyper-extending the first phalanges and flexing the two distal phalanges C A. Parker, of Chicago, believed that the deformity was due to the perversion of the normal reciprocal action between the flexors and extensors of the toes

Clinical Types —There were two main clinical varieties talipes arcuatus and talipes plantaris. In the former the heel and ball of the foot were in the same horizontal plane, whilst if the ball assumed a lower level than the heel, the condition was termed talipes plantaris Patients with pes cavus usually sought advice because of continued fatigue and pain in walking, due to the limited treading surface of the sole and excessive pressure on the heads of the metatarsals

Treatment —In slight pes cavus with a tendency to contraction of the toes the mother of the child should be taught to manipulate the toes and encourage the child to flex and extend them, a slotted metal splint being worn at night The boots must be long enough and roomy enough to give the toes due play Where the deformity was of moderate degree, with painful metatarsal callosities, a transverse leather bar should be added to the sole of the boot, behind the position of the corns If these measures did not give enough relief, an attempt should be made to flatten the arch by operation Formerly, Mr. Rocyn-Jones had tried to do this either by osteoclasis, by simple tenotomy of the plantar fascia with wrenching, or by excision of the plantar fascia He had now, however given up these procedures in favour of the Steindler operation Still, to that operation there were two serious drawbacks—namely, that sloughing of the wound edges occasionally

A CASE OF GONOCOCCAL ARTHRITIS,

WITH PATHOLOGICAL DISLOCATION OF THE HIP-JOINT

By E H Schwab, M D , B S Lond ,
ASSISTANT MEDICAL OFFICER, FEMALE V D DEPARTMENT,
GUY'S HOSPITAL

The following case of pathological dislocation seems to deserve record

A B , a single girl, aged 19, was admitted to Guy's Hospital on Sept 3rd, 1924, with a history of three to four months' vaginal discharge, for which she had received no treatment She had suffered from pain in the left hip for two months, and had been treated by rest in bed, and the application of a splint There was no history of injury to the hip The hip had become gradually worse, the least movement causing intense pain. The discharge had persisted, but was not very profuse

Condition on Admission —The patient showed signs of a typical upward dislocation of the left hip Her general condition was not good The temperature varied between 99° and 100° F , and her pulse averaged 110 On examination of the vulva, marked urethritis with inflammation of the Skene's and para-urethral ducts was discovered The cervix was found to be comparatively healthy, and it seemed that the chief site of infection was in the urethra and the ducts No gonococci were found in the first set of films taken from the urethra and cervix Cultures from the urethra grew *Staphylococcus albus* and *aureus* No pus cells nor gonococci were found in a catheter specimen of urine A skiagram of the left hip showed dislocation upwards and much erosion of the head of the femur

An anæsthetic was administered and a Thomas hip splint with overhead extension was applied to the left hip Local treatment for the discharge and urethritis was begun immediately.

After a few days the patient complained of pain in the right knee, which was found to be considerably swollen, with much limitation of movement The X ray report was as follows "Irregular rarefaction of articular extremities suggestive of infective arthritis No erosion of articular surface nor (apparently) of the cartilage" A week later the patient complained of pain and tenderness in the right loin She appeared extremely ill There was vomiting and hæmaturia She seemed collapsed after passing blood in the urine , temp 102 8°, pulse 120 Much blood was present in the urine , some specimens apparently consisting of almost pure blood This condition persisted for three days, when the urine was again free from albumin and blood Pathological report on the urine Two specimens were examined The clear specimen showed a few red cells, and pus also and some indefinite renal casts Albumin, say 0 5 per cent The hæmaturic specimen contained much blood and albumin in excess of the blood No pus or casts were seen

Films from the urethra now showed the presence of gonococci Cultures again grew *Staphylococcus albus* The urine examined later contained pus, *Staphylococcus albus*, and *Streptococcus brevis*, but no gonococci A month after the application of the extension apparatus the X ray report was "No dislocation now Infective arthritis with extensive erosion of the articular cartilage and of the underlying bone"

There was gradual improvement in the condition of the hip, and by the end of the year the patient was able to walk well with crutches The Thomas's splint had been replaced by a walking calliper with boot The signs of arthritis in the right knee had completely disappeared The vulvo-vaginal condition was much improved , only a slight mucoid discharge from the cervix and the para-urethral ducts persisting Films showed a few pus cells but no gonococci The patient was discharged from the ward and able to attend the out-patient clinic for treatment at the end of January, 1925

Treatment —On admission, local applications of protargol bougies to the urethra and protargol pessaries to the vagina twice daily also a daily intramuscular injection of 1 c cm of collosal manganese was given—about 15 doses in all. Later these were replaced by collosal iodine, 10 c cm every third day A mixture containing sandal oil and tincture of hyoscyamus was given by the mouth One dose of gonococcal vaccine (½ million) was given, but not repeated, because it was thought that perhaps the vaccine was the cause of the sudden exacerbation in the kidney

Whilst attending as an out-patient the cervix and urethra were swabbed at intervals with protargol and glycerine The patient had regular massage and was soon able to get about without a splint The hip became ankylosed and the left knee was stiff from disuse Manipulations of the left hip and knee were carried out under anæsthesia on two occasions The X ray report on the condition in December, 1925, was · "Hip old infective arthritis of hip-joint Bony ankylosis No evidence of activity Knee No evidence of disease Some degree of atrophy probably due to disuse"

The patient attended occasionally during 1926, reporting herself well each time Films taken from the cervix and urethra at each visit were free from gonococci In September, 1926, she was discharged as cured The local condition appeared normal She walked extremely well with her ankylosed hip, and the knee could be flexed to almost a right angle. Since then she has married, and is keeping perfectly well She can walk nearly a mile without feeling tired

My thanks are extended to Dr Morna Rawlins and Mr V Lloyd, and to Mr W. H Trethowan for kind permission to publish this case

A CASE OF
METASTATIC CARCINOMA OF THE CHOROID.

By Roy Thomas, M B , F R C S Edin ,
D O M S Lond ,
ASSISTANT OPHTHALMIC SURGEON TO THE SWANSEA GENERAL AND EYE HOSPITAL ,
AND
A F Sladden, D M Oxf ,
PATHOLOGIST TO THE HOSPITAL.

Carcinoma of the choroid is, perhaps, uncommon enough to justify the recording of the following case of bilateral metastatic carcinoma of the eyes involving the choroid The nature of the primary growth is of special interest

Clinical History

A man, aged 39, a congenital deaf-mute, was sent by his doctor to the Swansea General and Eye Hospital on Jan 11th, 1926 It was stated that a blow received on the left eye three months previously had been followed by gradual failure of the sight in that eye It was difficult to elicit accurate details, but the absence even of perception of light by the affected eye was evident The right eye had vision of 6/5 The left pupil reactions were absent There was no pain whatever Under homatropine both fundi were examined, the right being found apparently normal. The left disc was very swollen, but the rest of the fundus showed no abnormalities, even the vessels being of normal size

The man was admitted for observation but only remained three days owing to the restrictions placed on him His physical state appeared normal, as also his blood pressure and his urine Wassermann reaction negative , X ray examination did not help

A month later he appeared again The right fundus was still normal, but the left showed a totally different picture. The disc was now white and atrophic, and in the lower temporal area of the retina was seen a large flat detachment To its nasal side and apparently quite separate from it there was a smaller flat attachment Transillumination was very unsatisfactory

The patient refused admission but attended the hospital weekly for observation The detachment gradually spread over the whole fundus , there was still no pain Transillumination now definitely showed something solid beneath the retina The man refused to entertain the idea of enucleation of the left eye and avoided the department for three weeks At the end of that time he returned to complain of the right eye , examination revealed a small flat detachment on the upper nasal area of the retina, the disc was normal, central vision 6/7

After further irregular attendance he came to us a month later transferred from the Poor-law infirmary, now quite blind and very emaciated Severe hæmoptysis soon followed, physical signs of tumour in the chest were noticeable, and tenderness over the liver Two months later, having returned after a sojourn at home he came to us again, complaining of acute pain in the left eye A yellowish mass could now plainly be seen and the eye was acutely glaucomatous In the right eye the detached retina was plainly visible without an ophthalmoscope, but the tension was normal The left eye was enucleated and the diagnosis of carcinoma definitely established The patient died five weeks later (August 11th) and a post mortem examination from an abscess in the lung, although up to this time there had been no pyrexia at any time and no expectoration

Dr **C L McDonagh** showed radiograms demonstrating the pleural effusion and, after aspiration, the lung abscess and tumour

Dr **J Lait** described the post-mortem appearances

The right lung contained a large abscess and a tumour was found involving the root of the lung The pericardium was adherent and thickened and contained numerous pea-shaped metastases, which did not involve the heart muscle The tumour at the root of the lung surrounded and practically occluded the superior vena cava where it entered the right auricle The left innominate vein was thrombosed The spleen contained a small secondary deposit in its anterior border There were many retroperitoneal glands involved by the tumour spread, which had also invaded both suprarenals No metastases were found in the bones All the other organs and viscera were found free of any tumour

Microscopical examination of the primary tumour in the lung and its metastases showed a carcinoma composed of solid masses of spheroidal cells, supported by a fairly dense but variable stroma Many of the cells showed vacuolation —apparently an attempt at secretion In places there was an appearance of glandular formation

In an advanced malignant tumour of this sort, said Dr Lait, it was almost impossible to discover whether the cancer originated from bronchial or alveolar epithelium Microscopically he had identified the tumour growing in the lining of the bronchi, though the bronchi contained no tumour visible to the naked eye The localisation of the neoplasm to the hilus of the lung, with but little diffuse invasion of the lung parenchyma, suggested a bronchial carcinoma He thought that it had its origin in the mucous glands of the bronchus Discussing the tendency to classify all mediastinal tumours and lung tumours as either sarcoma or endothelioma, he referred to the recent investigation made by J B Duguid of Manchester, who had reinvestigated many mediastinal and lung tumours, and had found that many labelled as sarcoma or endothelioma were really carcinoma

Dr **William Boxwell** showed a specimen from a case of

Aortic Disease

The patient was a man aged 37 who had been admitted to hospital about a year previously in an acute stage of cardiac failure He had only been ill for four days, and stated that the condition had come on quite suddenly after an unusually hard day's work He was a coal-heaver, and said that he shifted 17½ tons of coal daily from a dump on to a lorry His heart was very much enlarged, and he had double aortic disease He recovered comparatively quickly from the acute failure, and in five weeks was able to walk about

Later, however, he returned to hospital with symptoms of cardiac failure, and on this occasion did not respond to any kind of treatment, and died rather suddenly

Dr Boxwell said that he had expected to find that the condition was of syphilitic origin and the patient said he had had syphilis many years previously The Wassermann reaction was positive But it seemed extraordinary that a man who had a syphilitic lesion could have done so much work, and could have had such a finely compensated heart From the naked-eye appearance or even from the microscopical appearance, it was impossible to know what the heart muscle was able to do

Dr **A R Parsons** described

An Unusual Case of Appendicitis

The patient was a man who had almost recovered from an attack of influenza. A week after the attack he became jaundiced, and wandered in his mind. The urine was dark in colour, and contained bile pigment. The patient did not complain of any definite pain. The knee-jerks were absent, there was no history of syphilis On admission to hospital his temperature was 99° F, his pulse was fairly rapid, and he was slightly delirious He became extremely restless, and the next day his urine contained bile pigment and a little albumin, and the ammonium salts were greatly increased

He was very violent during the afternoon, said Dr Parsons, and in the night he became collapsed, and died at 10 o'clock the next morning, two days after admission He had only been ill for ten days Throughout the illness there was no vomiting, and Dr Parsons had considered that the diagnosis lay between uræmia and acute yellow atrophy

Prof **J T. Wigham**, in demonstrating the specimens said that the patient had died of appendicitis There was fluid on the left side of the abdomen and apparently a subphrenic abscess It was interesting to note that the pus in the abdomen was on the left side, and the abscess was on the right side There was no abscess in the kidneys or spleen He was not quite certain of the cause of the jaundice, but thought it was probably due to an almost complete necrosis of the kidney, somewhat similar to that found in acute yellow atrophy

The **President** read a paper by himself and **C R Boland**, and **R A Q O'Meara** on

Variant Colonies of Staphylococcus aureus

He described how, by growing a typical *Staphylococcus aureus* (purified by six successive platings) in broth, and plating the broth culture at intervals a number of variant colonies could be produced The departures from the normal were in respect of · (1) Colour, some colonies were quite white ("*albus*") (2) Texture, some colonies were rough (R), in distinction to the normal smooth (S). (3) Cohesion, some colonies were viscid (V) In ordinary broth a large number of "*albus*" colonies were found after six days incubation, "*aur*, R, VV" colonies were plentiful after 33 days In glycerol-broth, in which the staphylococcus produced an acid reaction, "*albus*" colonies appeared as in ordinary broth but "*aur*, R, VVV" colonies at a much earlier period On agar, variants were produced but only in colour and viscidity; rough colonies were never found Similar results to these had been found with other staphylococci The variants, while they showed a considerable tendency to breed true, did revert, under certain conditions, to the normal type

A number of other communications were made

SECTION OF OBSTETRICS

At a meeting of this Section, held on Feb 4th (partly reported in THE LANCET last week), Dr. **Bethel Solomons** read notes on

Epistaxis as a Symptom of Toxæmia of Pregnancy

Having mentioned engorgement of the cavernous tissue of the nose was a symptom of pregnancy, and the rarity of epistaxis as a symptom of toxæmia he reported in conjunction with Dr T G Wilson, the following case

A primigravida, 26 weeks pregnant, came to the Rotunda Hospital with all the symptoms of toxæmia, these cleared to some extent, but three weeks later she returned with such intense epistaxis that it was necessary to plug anterior and posterior nares The urine was loaded with albumin and the blood pressure was 240

The patient was in imminent danger of death, and labour had to be induced After consideration of the various possible methods it was decided to do abdominal hysterotomy under spinal anæsthesia The preliminary morphine and scopolamine were so effective that stovaine was unnecessary, and the operation was performed without difficulty The nasal plugs were removed the following day She got on well on water diet, but unfortunately was given turkey and pudding on Christmas Day; this caused marked disturbance of vision, and the oculist, Dr F C Crawley, reported that she had retrobulbar paralysis She was kept first on water, then on light milk diet, and was finally transferred to a general hospital where she had improved considerably

Epistaxis, said Dr Solomons, might be regarded in the same light as toxæmic accidental hæmorrhage and the intra-abdominal and other bleeding seen in many severe types of toxæmia; but it was very rare

Dr **T G Wilson** said that it was seldom necessary to plug the posterior nares, but in this case it had been absolutely necessary in order to stop the bleeding, though he thought that if the patient had not been followed, and that there was a delay in the after-treatment. Steindler himself now operated through an incision on the inner side of the foot, extending from the back of the heel to a point in front of the anterior end of the os calcis Three weeks after the operation the patient commenced to walk in soft shoes, and he was also taught toe exercises.

In pes cavus of severe degree with gross bony deformity, every step by the patient was painful, and an attack on the soft parts alone was unlikely to bring relief In such cases, he thought, the Steindler operation should first be performed, followed later by bone-resection He favoured cuneiform tarsectomy at the point of maximum convexity of the arch In cases where the bony deformity was not very great but there was much dropping of the head of the first metatarsal, a good deal of improvement could be brought about by the following method which Mr. A. H Tubby had shown him A few weeks after the sole had been stretched by Steindler's operation an osteotomy of the first metatarsal was performed at the junction of the anterior third and posterior two-thirds The corrected foot was encased in plaster for six weeks, and then treated by massage and exercises. Sometimes, in combination with an operation on the plantar fascia, it was necessary to cut the extensor longus hallucis and re-attach it to the first metatarsal, the distal end being joined to the extensor brevis hallucis The result, however, was sometimes disappointing There was little scope for arthrodesis in essential cavus, said the speaker, but it was very effective in flexion of the great toe with a painful dorsal corn In conclusion, he pointed out that pure cavus deformity was not very common, but cavus was frequent in association with other deformities Symptoms usually developed during adolescence, though the exciting cause might have been an illness at a remote date There was a dropping of the foot due to weakness or paralysis with resulting secondary contracture of the plantar fascia, forcing the bony arch to expand upwards during growth The form of treatment called for depended on the degree of the cavus Proper after-care, in the way of splinting, exercises, electrical treatment, and footwear, was important.

Discussion.

The PRESIDENT thought that the profession insufficiently appreciated the fact that mild pes cavus was apt to follow an acute illness Children who had been kept in bed for a long time often suffered afterwards from mild pes cavus, and those kept in bed for more than a few days should have the weight of the bed-clothes taken off the feet by means of a low cradle They should also have daily ankle and toe exercises.

Mr. NAUGHTON DUNN said that it was common to see a cavus deformity in which there was no shortening of the tendo Achillis, and that, he thought, was the true pes cavus It often resulted from a weakness of the dorsiflexors of the ankle; the extensors of the toes, in their effort to dorsiflex the foot, caused dropping of the metatarsals and shortening of the structures of the sole of the foot This type was usually well treated by division of the plantar fascia and the structures attached to the os calcis, by Steindler's or some other simple operation, the important point being that there should be complete over-correction of the deformity after the cutting part of the operation The type of cavus deformity which caused most difficulty, and in which he was most interested, was that which occurred in children of 5 to 7 years of age, and was of insidious onset It was progressive, and he did not know what the cause was By division of the plantar fascia and the structures attached to the os calcis good correction of the foot could be obtained by wrenching and complete over-correction The result appeared to be good, but there was a great tendency to relapse This could be prevented by dividing the tibialis posticus tendon

Mr. R. OLLERENSHAW spoke in advocacy of the operation of transplanting five tendons Within four years he had done 33 operations of that kind on 27 patients During the same period he had had only three cases of pes cavus which required a bone operation

Mr WHITCHURCH HOWELL thought that division of the plantar fascia should be done less and less, and in a mild case only if a metatarsal bar was not sufficient The transference of the extensor longus pollicis through the neck of the metatarsal bone should be condemned, for it was anatomically unsound During the last five years he had used a modified Steindler's incision; instead of the horse-shoe incision he made two short incisions, one on each side of the os calcis.

Mr. H A. T. FAIRBANK said that for some years he had been in the habit of making an incision on the inner side of the foot to divide the ligaments which the Steindler operation did not enable the surgeon to reach. It was advisable to divide the ligaments between the internal cuneiform and the metatarsal, it made it possible to correct a bad case Sometimes after the Steindler operation he had seen nasty lumps in the sole of the foot, and Steindler himself was careful not to do a subperiosteal operation at the tuberosity of the os calcis; he cut just superficially to the periosteum. In order to prevent relapses, Mr Fairbank had, in a number of cases, transplanted the extensor tendons into the heads and necks of the metatarsal bones, and had been pleased with the results

Mr. P J VERRALL spoke highly of the method of tendon transplantation He had done it about 15 times, and had been very pleased with it In the Steindler operation he employed an inch incision on the inner side, using the knife and cutting above the tuberosity of the os calcis, separating the lower part of the heel from the sole with the knife, and then using the periosteal elevator above the incision

Mr C LAMBRINUDI said that Mr W H Trethowan had been advocating the Steindler operation combined with scaphoidectomy, which had the advantage of a wedge incision and of leaving two cartilage-covered surfaces opposed to each other. Mr Trethowan and he had operated on a fair number of cases in that way, and it enabled them to flatten out the arch very well With regard to the toes, he had recently treated a case by arthrodesing every one of the interphalangeal joints, so as to get over the occurrence of clawing of the toes That converted the flexor longus digitorum into interossei, whose action was the one thing which was lacking in claw toes

Mr. ROCYN-JONES, in his reply, said that he believed in bone operations only for very severe deformity In some cases he did not see how the cavus could have been got over except by a drastic operation, either a bone operation or one like Mr Dunn's In severe cavus the bugbear was inversion of the heel.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

A MEETING of this Section was held on Feb 11th, Prof J. W BIGGER, the President, in the chair

SIR JAMES CRAIG reported on a case of

Primary Carcinoma of the Lung

A man, aged 51, was admitted to hospital on Nov 1st, 1926 His doctor said that he had a pleural effusion, and that about a pint of blood-stained fluid had been drawn off

On examination the face and ears were cyanosed, the upper thoracic region was œdematous with distended venules, and the arms and hands swollen from œdema. There was no enlargement of liver, no ascites, and no œdema of feet or legs There was a right pleural effusion The patient had a dry cough, but no accompanying expectoration

On Nov 14th the chest was tapped and 15 oz of blood-stained fluid withdrawn Later dyspnœa increased and the patient died on Nov 21st. Two days before his death he coughed up a quantity of foul smelling pus, evidently as neurosis, chronic parenchymatous nephritis, utero-ovarian disorders, and adenoids. Arterio-sclerosis is not mentioned in the list of causes of this symptom, nor is there any hint that the practitioner should take the blood pressure of patients complaining of occipital headache. The list of the chief signs of chronic parenchymatous nephritis is also misleading; these include œdema beginning in the face, increased arterial tension, diminished urine output, and high blood-urea The method of attempting to give causes in order of importance also leads to the presentation of a long list of diseases which would be clearer if classified on some definite plan. This is particularly obvious in the section on dyspnœa (p 391) where 32 common causes are set out in heavy type and a large number of less common causes in smaller type. There does not seem to be anything to account for the order in which any of these causes appear Such a book is hardly likely to help even that practitioner who finds "that his memory is defective and that he has perhaps forgotten or never knew many of the causes of that symptom." It is, indeed, questionable whether a book deliberately planned to make medical diagnosis merely a turning up of symptoms and finding the highest common factor of a number of causes has any value. Unlike treatment, diagnosis can never be satisfactorily tabulated; it surely comprises the whole of medicine

Ultra-violet Rays in General Practice

By W. ANNANDALE TROUP, *M.C*, M.B St Andrews London: H. K. Lewis and Co, Ltd 1926 Pp 59 *4s. 6d*

THE author of this small book pretends to no life-long acquaintance with the subject on which he writes for he tells us in his preface that it gives "the experience of the author in ultra-violet ray treatment in his general practice during the last year." He hopes that it may stimulate others to utilise "this beneficial form of treatment" Those in whom enthusiasm is tempered by caution will probably consider that a longer experience of any form of therapy is necessary before conclusions of value can be drawn from it

The first 30 pages of the book are devoted to a brief historical and scientific sketch of the subject and the technique of the therapy. Then follow 24 pages on the actual therapeutic applications and 5 pages of index, which seems a little out of proportion to the length or weight of the letterpress The value of the book lies in the fact that it may induce readers to seek more information, while as far as it goes it is sound.

Transfusion of Blood

By HENRY M FEINBLATT M D, Assistant Clinical Professor of Medicine, Long Island College Hospital Brooklyn, N.Y. The Macmillan Company. 1926 Pp xiv. + 137. *12s. 6d*

THIS monograph gives in a compact form the main facts concerning the history, theory, and practice of blood transfusion. The information is up to date, and the author adopts a judicial attitude towards the much-discussed question of citrated versus whole blood He regards both methods as of great value, and admits that there is no evidence that citrated blood is really injurious. His own preference, however, is for whole blood and he describes at length a method depending upon the use of a syringe apparatus of his own design This, in common with most whole blood methods of transfusion necessitates the presence of the donor by the side of the recipient, so that it is unsuitable as an adjunct to a surgical operation Dr Feinblatt regards the classification of blood groups as being at present in a state of flux, owing to the discovery of other factors in addition to those present in the four Moss-Jansky groups The author, however, has evidently found that in practice the usual four-group classification is a satisfactory working hypothesis

The Essential Oils.

By HORACE FINNEMORE, B Sc Lond, F.I.C. London. Ernest Benn, Limited 1926 Pp 880. *70s*

THE essential oils are of great technical and commercial importance being used not only in medicine but in the manufacture of foodstuffs and perfumery. The quantities imported into, and re-exported from, the United Kingdom every year are immense. Many of the essential oils are complex mixtures containing a number of different constituents; others are comparatively simple substances Their chemical constitution shows a wide range of variation from compounds of low molecular weight to those intricate substances, the terpenes, which are characterised by a number and variety of closely related substances Although many of the constituents of essential oils can be produced artificially, the oils are still obtained mainly from the plant world. The British Empire, with its varied climates and soils, should provide many of them, and Mr. Finnemore emphasises the comparative neglect of potential sources within the Empire

The arrangement adopted is that of the natural orders of which 76 are dealt with, including lichens and liverwort, and 2000 oils are described. It is claimed that the book gives for each oil its botanical source, cultivation, commercial production, chemical composition, physical characters, methods of analysis, and uses in industry, but actually this ideal is impossible of achievement in reasonable space; the descriptions of the oils of turpentine and eucalyptus alone occupy 46 and 70 pages respectively. The labour entailed in compiling such a work must have been considerable, and could only have been undertaken by one possessing first-hand technical experience. Most of the recent advances have been embodied in the text so that the information is up to date; where the chemistry of the substances is particularly complicated the formulæ of the various compounds are set forth in tabular form, showing their inter-relations Some parts are rather scrappy or obscure and the botanical sources of oils described are not always clearly stated; but the book will be welcomed as a valuable source of information as to the nature, origin, and uses of the essential oils

Pædiatrics.

Common Procedures in the Practice of Pædiatrics. By ALAN BROWN, M B, and FREDERICK F. TISDALL, M D, Physicians Toronto Hospital for Sick Children Toronto: McClelland and Stewart. 1926 Pp 260. $4.

THE object of this book is to bring within the reach of students and practitioners the methods employed in the children's hospital at Toronto. The authors have adopted the plan of describing a selected number of procedures in sufficient detail to enable the practitioner to carry them out without further information. The chapter on artificial feeding of infants has the merit of being simple; a clear account is given of the use of diluted cow's milk with added carbohydrate, which is presented as the method of choice for thriving infants who cannot be breast-fed. Considerable attention is paid to the diets of older children, and many valuable hints are given about their general management The technique of a number of therapeutic and diagnostic procedures, such as the parenteral administration of fluids and of chemical and biological reactions is lucidly described, but the encouragement to use the superior longitudinal sinus for the introduction of fluids will not meet with universal approval. A useful chapter on difficulties in diagnosis prepares the reader for some of the pitfalls with which he may be beset in the examination of sick children

This book should be of considerable use as a supplement to a text-book, both to the student and to the practitioner pregnant the loss of blood would have probably done her good, as it would have brought down her blood pressure, which was very high. The condition appeared to be rare Referring to treatment by X raying the spleen, he said that if this case had not been so urgent this method of treatment would probably have been successful, as it would have brought down the high blood pressure, which he regarded as the cause of the epistaxis

The CHAIRMAN was scarcely inclined to regard this case as one of toxæmia of pregnancy, he thought it more probably a case of severe nephritis supervening on pregnancy In the vast majority of stillbirths the cause was underlying bad health of the mother In this case the condition must have been present for some time, as it seemed to him unlikely that retrobulbar neuritis would come on 24 hours after the taking of solid food Ocular symptoms such as optic neuritis, of course made the prognosis in these cases much more gloomy

Prof A H DAVIDSON, referring to the termination of pregnancy in this case, asked if it would not have been less of a shock and less danger to the patient if labour had been induced by means of a stomach-tube instead of by opening the abdomen Labour in these cases of albuminuria and toxæmia was usually very easy.

Dr D J CANNON said that whilst, from the point of view of reducing shock, it was best to employ spinal anæsthesia, he thought that it was supposed to be bad in cases of high blood pressure, and the patient in this case had had a high blood pressure He agreed with Dr Cassidy that the case appeared to be more one of nephritic toxæmia than of toxæmia of pregnancy Sometimes ocular symptoms occurred in pregnancy, but cleared up immediately afterwards He thought that Dr Solomons had been quite right to empty the uterus in this case In nephritic toxæmia the great danger was severe deterioration of the kidney.

Dr G. TIERNEY asked if Dr. Solomons had found in the literature any case of epistaxis as serious as the two cases which he had reported He himself had had a case of epistaxis recently in a woman five months pregnant, but the epistaxis was checked by the administration of calcium lactate She, however, had not had albumin in her urine

Dr SOLOMONS, in reply, said that he thought it was a true case of toxæmia, many women dated their troubles from a supposed chill or trauma, and little attention need be paid to them The urine had been normal before pregnancy It was a fallacy that the toxæmias of pregnancy occurred only in the later months; he had seen many examples in the fourth, fifth, and sixth months, and they were most difficult to treat Abdominal hysterotomy was the method chosen because it was quick, and speed was necessary X ray treatment of the spleen would not have been suitable for the same reason He did not fear the possibility of sudden diminution in the blood pressure with spinal anæsthesia He agreed it was difficult sometimes to differentiate between a true nephritis and toxæmia The literature on the subject of epistaxis in pregnancy was meagre

---

ROYAL MEDICAL BENEVOLENT FUND —The following are some additional cases relieved at the last meeting —

Widow, aged 55, of M B who died in 1923 No children Supplements her income of £35 per annum by taking paying guests Lives in her own house rates amount to £25 per annum There has been no paying guests for the past three months so the applicant asks for a little help Voted £18 in 12 monthly instalments

L R C P, aged 70 Owing to age is unable to obtain work, and about three weeks ago had a stroke He is now in a home and is dependent upon charity, as his savings are exhausted Previous help given by the Fund amounts to £68 A further sum of £15 was voted

Subscriptions may be sent to the Treasurer, Sir Charters Symonds, at 11, Chandos-street, Cavendish-square, London, W.1.

Reviews and Notices of Books.

TREATMENT OF CHRONIC ARTHRITIS AND RHEUMATISM

By H WARREN CROWE, D M, B Ch Oxf., M R C S, L R C P London · Humphrey Milford, Oxford University Press 1926 Pp 196. 8s 6d

Dr. Crowe here offers to the clinician and general practitioner his matured views on the causation and treatment of rheumatic disease This volume is only the first half of a work to be completed by another section devoted to theoretical argument and a description of experimental technique for the benefit of the bacteriologist and specialist It is, however, complete in itself Dr Crowe believes that chronic arthritis is a disease caused by bacteria, and has evolved a form of vaccine therapy for which he claims not only better results than from any other treatment, but the power of stamping out, if applied in the early stages, practically all forms of arthritis The two conditions of rheumatoid arthritis and osteo-arthritis have each, according to him, their own causal organism ; the latter disease is attributable to a non-hæmolytic streptococcus, while the former he believes to be caused by a certain group of white staphylococci, described by him in 1912 and named *Micrococcus deformans* Both organisms are alleged to be present in either condition, but as primary and secondary infections respectively Since their toxicity is low, he believes that the system does not generate immunity against them, and that the way to cure them is to raise the resistance of the body. The author admits that observers of the calibre of Prof Stockman and Dr S Boorstein have either ignored or condemned vaccine therapy of chronic rheumatism, but, in his view, the fault has hitherto lain in the method and not the theory Those who have tried and failed have, he says, not sufficiently realised and allowed for three important factors—the variability of the bacterial flora, the magnitude of the diseased area, and the frequent intolerance of patients to vaccines These obstacles he claims to overcome by the use of sufficiently polyvalent vaccines, by very careful dosage according to Wright's law that the dose should be inversely proportional to the amount of the disease, and by careful allowance for sensitivity, which may be essential to the cure

Dr Crowe is an enthusiast who writes in an interesting and persuasive manner The trial of his methods by impartial practitioners is certainly desirable

SYMPTOM DIAGNOSIS

Regional and General By WILFRED M BARTON, A M, M D, F A C P, Associate Professor of Medicine, Medical Department of Georgetown University, and WALLACE M YATES, A B, M D, Fellow in Medicine, Mayo Foundation, Rochester London and New York D Appleton and Company. 1927 Pp 851 £2 2s

THIS book is designed "for quick reference while the patient is being prepared for examination or while he is dressing after the examination" Granted that such a sort of book is desirable, then the authors may be congratulated upon having produced a remarkable, complete, and concise volume It consists first of all of regional symptoms, considered under such headings as "the jaw," "the larynx" "the lower extremity," and so on, then follows a section of nearly 200 pages on general symptoms, containing very complete articles on such subjects as insomnia, obesity, diarrhœa, and dwarfism This part of the book contains little which can be criticised unfavourably Elsewhere it is more vulnerable, since the main scheme, to arrange the causes of various symptoms "in order of importance," is not very successful in practice For example, the first four causes of occipital headache (p 7) are given

I THE LANCET.

NDON: SATURDAY, MARCH 12, 1927

THE PATENTING QUESTION.

application made by G F and G H Dick atent in respect of what are labelled "improve- in scarlet fever toxin and antitoxin and ls for producing same" will cause considerable ension A specification has been deposited Patent Office in respect to the discovery of a of isolating hæmolytic streptococci specific et fever, growing them in a suitable medium aining therefrom toxin and antitoxin specific et fever Patents in this respect, it appears, ng *obtained both in England and America* tent specification includes the processes for ng the antitoxin, the method of using the kin for tests, and other connected processes em of monopoly is allowed to pervade medical what is to be the end of it ? What is revent the monopolist from stifling research, g the manufacture of vital remedies, or from 40 rices so high that the poor patient will have ct of competing for them against the rich ? nts and Designs Acts contain provisions Government departments can intervene processes in special cases *In naval and* atters monopolies are not allowed to prevent from equipping itself with the necessary *self-protection* Is it not time to apply inciples to the fight against disease ?

s of great importance are raised by this ndency to use the methods of commercialism duction and protection of medical remedies ars *ago*, when E von Behring patented heria antitoxin, professional opinion in and elsewhere was naturally hostile to the f personal fortunes *from* biological patents ; was everywhere ignored, and no effective s made by the patentee. Since then the o use the machinery of patent laws for fit of the discoverer of a drug or pro- ve been chiefly concerned with new drugs, of which salvarsan is an *example* years, however, another invasion of com- n into the marketing of biological products manifest Insulin was patented by *the* y of Toronto presumably in order that eeds might be used to further research ate, no selfish use has been made of the This result was doubtless the outcome licious intervention of the Medical Research whose immediate action prevented the rom being flooded by imitation products, ed a safe and cheap supply as quickly as in this country. In other hands such a patent might easily have been abused. As a general rule, however judiciously money derived from the sale of patent remedies is expended, the exclusion of free competition in manufacture and the payment of royalties may keep up prices, and so prevent the full benefit of a new remedy or a diagnostic test from reaching the largest possible public A further possibility of abuse occurs when the business firm to which a new product is entrusted by the patentee is unable or unwilling to provide a potent preparation on a commercial scale, while other firms are not allowed to attempt to do so We called attention more than a year ago to the double confirmation of the work of E Herrmann and S Fränkel (1915), *who prepared* an active extract of the ovarian hormone by a method patented by them on Feb 13th, 1918 (E P 113, 311) We still await the large scale production of a standardised active extract of this hormone. None of the commercial material which has reached this country appears to fulfil *the biological test of* producing œstrus when injected subcutaneously into a female rat As a pleasant contrast, manufacturers were left free to produce for commercial purposes a parathyroid extract prepared by Collip's method, and we have already been able to publish accounts of the valuable clinical results obtained by its use

So long as protection by patent was confined to what are known as patent medicines, the matter was not overwhelmingly serious There were objections to the system which invests the pill and the cough mixture with magic qualities in excess of their merits, but the general improvement in public knowledge has mitigated these evils ; medical men may think hardly of the situation, but the Exchequer will remember that a not inconsiderable revenue is derived from the stamp duties on proprietary medicines Selfishness is not a vice of which its worst critics have hitherto been able to accuse the medical profession or the research worker in this country Medical ethics reject monopoly What is to be the effect upon research if the Patent Acts are invoked to protect each stage in scientific progress ? Rewards will be claimed for the man who gives some finishing touch, perhaps almost accidentally, *to work* done by men in many countries and for many years without reward Indeed, if we glance again at the naval and military parallel, it is notorious that the special machinery for remunerating inventors in respect of devices used in the Great War has been open to much criticism, both on general principles and in the matter of particular awards Medical research, *conducted in the public interest*, is as incompatible with secrecy and shut doors as with legal injunctions or heavy royalties Present tendencies are disquieting and indeed alarming Public opinion needs to be aroused and action taken The medical profession will unhesitatingly repudiate the commercial exploitation of scientific discoveries which relieve pain and cure or prevent disease In this condemnation it should be sure of the support of public opinion, having successfully combated the evils of monopolies three hundred years ago, this country is not likely to tolerate them to day in the sphere of medical treatment

PHILOSOPHY

The Meaning of Disease. By WILLIAM A. WHITE, A M, M.D. London. Baillière, Tindall and Cox, Baltimore: Williams and Wilkins Company 1926 Pp 220 13s 6*d*

THE author is concerned to urge upon medical men that they should take a more philosophic view of the subject of their study. In the rush for the discovery of new facts by the analytic method and in the constant refinement of technique there is too much neglect of that laboratory in which the equipment is ideas and intuitions, the procedures being processes of thought The part of man which needs more attention is the psyche, and his social relations, which equally constitute an essential part of him, are also not considered as much as they should be. Dr White writes in an interesting way and he certainly preaches from some striking texts; we may quote three. "Nature must be considered as a whole if she is to be understood in detail" (Bunge), "A fit organism inhabits a fit environment" (L J Henderson); "The last thing to be discovered in any science is what the science is really about" (Whitehead) It is good for us to be reminded of such sayings as these, they are worth thinking about. The book is nicely produced, but it is somewhat costly

---

THE DANCE OF CIVA.

Life's Unity and Rhythm By COLLUM London Kegan Paul, Trench, Trubner and Co Pp 94. 2s 6*d*

THE conviction that seeming diversities and differences are but passing and rhythmically varying phases of a fundamental unity led the philosophers of the East to symbolise Life and Death as the continuously flowing Dance of Civa in which construction and destruction are pulsating patterns This conception is designed to teach us that many of the phantom barriers and conventional categories which we erect have no real existence It may be so But to common mortals barriers and categories are a necessity for any mental process which may reasonably be called thought, and it is perhaps because he is so sure that they ought to be neglected that Collum has written such a nebulous and unconvincing essay

New Inventions.

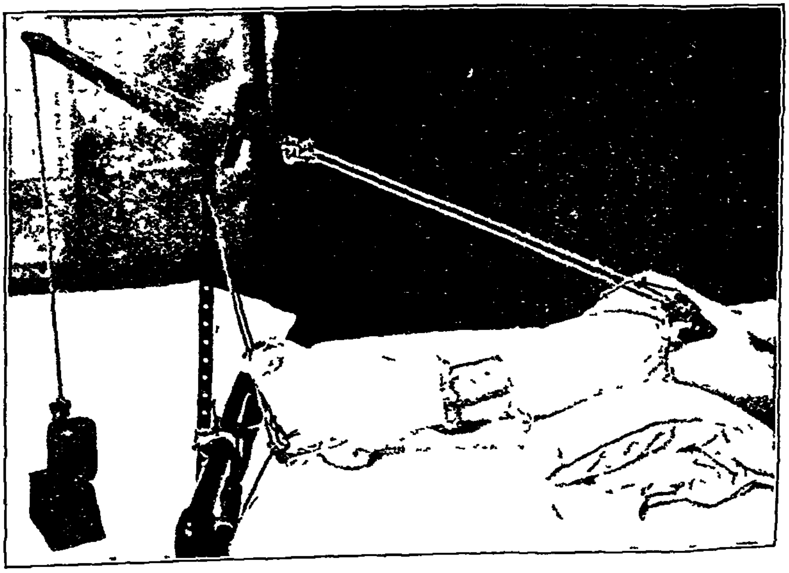
AN INTERRUPTED PLASTER FOR FRACTURES OF THE LEG

THE accompanying photograph illustrates the application of a simple and generally available form of splint for use in the treatment of fractures of the bones of the leg in the middle third, a common type of injury, especially from "run-over" accidents Plaster bandages and the knee-flexion piece of a Thomas splint are the only requirements for fixation

The method of application is briefly as follows:—

The patient is anæsthetised, and the leg cleaned, rubbed with spirit, and powdered, appropriate treatment being carried out for a wound, if such exists, and a dressing applied Before any covering is placed upon the foot or knee, a line is drawn with a skin pencil from the inner border of the patella, vertically upwards on the thigh, in order to indicate the proper alignment—i e, the relation of the great toe to the inner border of the patella, when the knee is covered up Lint, padding, and a few turns of plaster bandage are then applied to the foot and to the region of the knee, which is slightly flexed, a space of 3 inches being left at the site of fracture The flexion piece of the Thomas splint is placed in position and the plaster application continued, loops being made round the limbs of the splint in order to prevent slipping The joints above and below the fracture are thus fully immobilised, and the fragments of the long bones are held in position to within a short distance of the actual site of fracture When the leg alone is affected, a considerable *amount* of wool and a reinforced plaster are applied over the *sole* of the foot, so that the metal cross piece is entirely covered in, and with this form of ambulant splint the patient can be *allowed* out of bed, with the use of crutches, in two or three days For purposes of massage, the plaster can be readily bi-valved by cutting behind the metal side bars

Where the femur and leg bones on the same side are involved, extension is usually a matter of difficulty, but the method described here has been found serviceable in two cases of this type In the first, the leg splint was applied in the manner described, a Thomas splint was then placed in position, with underslinging bandages to the thigh The upper ends of the flexion pieces were rested upon the side bars of the Thomas splint in the usual way, but not clamped, so that traction upon them was effective in extending the femur



The case illustrated is that of a lad of 16 years, who sustained a simple comminuted fracture of the tibia and fibula, and a transverse subperiosteal fracture of the femoral shaft, *while* stopping a run away horse A pillow *under* the thigh was found to give sufficient support at this level, as the extension pull on the upper ends of the metal side pieces preserved the essential *for*ward curve of the femoral shaft, the knee being plastered in flexion

In addition to having led to satisfactory local results, the method has these advantages In compound fractures, local wound treatment does not interfere with fixation Swelling at the level of fracture is not followed by painful pressure and so the plaster can be applied upon the first occasion when reduction is effected The box-splint stage is thus eliminated, and the use of Sinclair's *skate or other* form of traction on the foot has seldom been found necessary The *condition* of the soft parts can be observed throughout, and radiographic inspection is better than in the full plaster Extension to the femoral shaft is simplified incases in which fractures exist above and *below* the knee in the same limb

J. J M SHAW, M D, F R C S Edin,
Surgeon, Leith General Hospital Assistant Surgeon, Royal Infirmary, Edinburgh

The petition to be addressed to Parliament by the National Canine Defence League, with which the Royal Society for the Prevention of Cruelty to Animals is not associated, expresses the opinion that "the dog has of late years been specially selected by vivisectors for extensive and peculiarly revolting and painful experimentation." The same petition speaks of "demonstrations of a prolonged and agonising nature before classes of students." Sir THEODORE COOK, in a letter in the *Times* of March 7th, recalls the fact that on the back of the entry forms of Cruft's Dog Show was printed an imaginary picture representing an operation performed in France about 100 years ago by a man who died in 1855; beneath the picture was displayed the following sentence: "209,014 experiments on living animals were performed during 1925, many of these being upon dogs." Obviously, as Sir THEODORE COOK observes, the uninstructed reader is intended to infer that operations of the kind illustrated in the picture are constantly happening in England to-day. He asks whether Lord BANBURY or Sir ROBERT GOWER knew of any instances of dogs suffering severe pain after recovery from anæsthetics which were not put to death as humanely as the 28,565 dogs destroyed in the Battersea Dogs' Home during the same year. We look in vain in all the mass of antivivisectionist propaganda for any fair admission of the extent to which dogs are protected by the existing law, or of the measures taken (under strict Home Office regulation and inspection) to prevent the infliction of pain. Nothing is said of the elaborate precautions which govern the licensing of the research worker, of the substantial safeguard which insists that his application for a licence shall be signed and countersigned by responsible authorities, of the special certificate which is required if feeding experiments or inoculations are to be done, or of the fact that 95 per cent. of the total number of so called vivisections come within the class covered by this special certificate. Nothing is said of the fundamental restrictions imposed by the Cruelty to Animals Act of 1876, or of the further restrictions made by the Home Office thereafter. Nothing is said either of the additional safeguards (under Section 5 of the Act) whereby experiments on a dog or a cat are even more stringently regulated. Nothing, finally, is said of the profound benefits to the human race which have resulted from the carefully restricted and officially supervised employment of experiments upon animals in the alleviation of human pain and the cure and prevention of human disease. Information in this respect has been issued in publications more accessible to the medical profession than to the general public. Of the technical details of that information the supporters of the Bill may naturally be ignorant, but there is one aspect of experiments upon animals of which every dog-lover should know. The study of distemper may not only help us to understand and repel certain obscure diseases from which mankind suffers, it also holds out the reasonable prospect that, sooner or later, a great menace may be removed from the canine species. The so called Dogs (Protection) Bill will bar the advance of science towards the finding of a remedy. It may not unfairly be given the title of the Dogs (Continuance of Distemper) Bill.

Distemper is but one of many problems for the research worker, but what is the attitude of the supporters of the Bill towards it? Their avowed purpose is the total prohibition of all experiments which may promote the cure and prevention of this disease. Sir THEODORE COOK quotes the chairman of an antivivisectionist meeting held last January as having said that the Field Distemper Council had spent three years "in torturing dogs in the most abominable manner." If this were so, why did not the Royal Society for the Prevention of Cruelty to Animals, which seems itself to be concentrating upon a merely antivivisectionist policy, prosecute the offenders to conviction? In the debate on Lord Banbury's Bill in 1925 Lord LAMBOURNE, who supported the Bill, found it necessary to concede that the Bill might be amended so as to make an exception in favour of distemper experiments. Logic we have learned not to expect in the discussion of this subject, but, if distemper experiments are admitted to be unobjectionable, what becomes of the principle of the Bill?

Annotations.

"Ne quid nimis."

THE LISTER DOCUMENTS

DURING the forthcoming Lister centenary celebrations the cabinet containing Lord Lister's instruments, manuscripts, diplomas, and other papers, which occupies a position of honour in Room I. of the Museum of the Royal College of Surgeons of England will be a centre of peculiar interest. A noble piece of furniture, the cabinet was the late Sir Rickman Godlee's tribute to the memory of his illustrious uncle. In it behind glass are displayed Lister's instruments and the same collection is continued in another case against the neighbouring wall, which forms a companion collection to the relics of John Hunter in a similar museum case close by. Lister's documents, however, are only partially visible to the public eye, and a number of them, beautifully bound and cared for by his nephew, are locked up in the cabinet drawers. Very interesting among the latter are a number of diagrams of bacteria and general pathology, and also the rolls of common paper, some half-dozen in number, on which over 40 years ago Lister caused a horse, a dog, and a rabbit to place on record the relative pressures of blood in systole and diastole. The elaborate conclusions which he then reached are fully set out in Vol. III. of his "Common Place Book," a work in four volumes here preserved behind a glass door. These books contain the record of the successive experiments in which the great surgeon engaged. They are largely in the handwriting of Lady Lister, who laboured with devotion in her husband's behalf till death cut her off, sadly and suddenly, when the pair were on their travels in March, 1893. Sir Rickman Godlee, in his biography of Lister, has painted a vivid picture of the manner in which these manuscripts were written, often long after midnight, owing to Lister's unwillingness that anything should be set on record till he himself felt sure of it. The illustrations, almost all by the investigator, are fine examples of delicate draughtsmanship, and many who see them will be surprised to learn that he was an anatomical artist of such a high order. The most important volume in the collection under discussion is without doubt the slim folio labelled by Godlee "Notes and Drawings Suppuration Lister *1851-1907*." This is the very scripture of Listerism, a treasure beyond price.

Of the other MSS. in the collection there may be mentioned also five letters from Pasteur, in one of which the famous Frenchman speaks of having heard dimly during many years of his English colleague's special investigations and testifies to his own interest in them. He writes as a sick man, his head hanging painfully in sympathy with his semi-paralysed side. The originals of Lister's principal courses of lectures in Glasgow, Edinburgh, and King's College are also

THE RHEUMATIC HEART.

THE failure of even a rigid system of rest to stem the progress of rheumatic carditis once it has manifested itself is a disappointing fact to which attention was last year drawn by Prof J A NIXON[1] after careful study of children warded in the Southmead Hospital at Bristol They do not dispute the observation made by FRANCIS SIBSON in 1877 that cases of rheumatic fever are less often attacked by rheumatic carditis when kept strictly at rest This dictum is now regarded as definitely proven, and indeed forms the basis of the modern treatment of acute rheumatism ; but enthusiasts have hoped that where rest has preceded as well as followed signs of a pathological state of the heart, complete restoration of function might ultimately ensue Dr CAREY COOMBS in a Chadwick lecture, which we print on another page, quotes hopefully evidence of " a surprising number of apparent recoveries, even among children whose hearts have undoubtedly been damaged " The observations made at Southmead do not encourage this optimism Even if the patient is actually in a hospital bed when the earliest signs of cardiac involvement are detected, Dr NIXON and his co-workers do not now believe that its progress can be arrested or that however long the child is kept at rest a really sound heart will result

If further experience confirms this distressing prophecy, it is the more urgent to seek means to prevent the primary disease Dr NIXON points out that in a sense this is being achieved, relatively at least, by means of some unknown factor in the life of the upper classes, since rheumatism hardly exists in our great public schools In an introduction to a report on Social Conditions and Acute Rheumatism, which we summarise on p 562, Dr G F STILL confirms the rarity of this condition among well-to-do patients ; indeed, this well-recognised class-incidence of rheumatic fever, as one of the few things certainly known about the disease, gave hope to the investigators working in London and Glasgow under the auspices of the Medical Research Council that even in the absence of any secure knowledge of its causation, a careful study of environment might indicate means for prevention or at least reduction But when the hospital patients under investigation were divided into three classes it was found, contrary to expectation, that a comparatively small proportion of the rheumatic cases came from families belonging to the lowest class, where the children have insufficient and unsuitable food, clothing, accommodation, and outlet, and suffer also from lack of discipline, regular meals, and sleep Nor did inquiry into heredity yield much clearer results In 260 out of the 721 rheumatic families examined—or 31 per cent —there were, it is true, one or more persons in addition to the rheumatic patient suffering from rheumatism The general picture presented by these family histories, however, is that of rheumatism attacking several members of one generation rather than of the disease being handed down from one generation to another, though diagrams of some 300 family trees set out on pages 23 to 30 of the report suggest that there is some hereditary predisposition to attack in rheumatic families The infrequency of rheumatism in the four Poor-law residential schools studied—1 per cent against some published statistics of 3 6 per cent in elementary schools—lends no support to a theory of heredity, while it does confirm the idea that a high standard of food, clothing, housing, and general care has some influence in preventing the disease Dr STILL does not ignore the possibility, however, that the comparatively sequestered life of these children in a community which has little contact with the outside world may involve less exposure to infection This view would imply that rheumatism may be conveyed by infection, which assumption is difficult either to accept or to reject The incidence of rheumatism among those in close contact with a known sufferer was high enough to suggest to Dr STILL and his co-workers the possibility of transmission of the disease, though no conclusive evidence of contagion from case to case has been obtained Of 382 persons sleeping in the same room as 192 rheumatic children, 59, or 15 per cent, were rheumatic In the light of these findings the cautious family doctor may consider it his duty to advise, at least, some degree of isolation, thereby laying himself open to unanswerable questions about periods of infectivity and incubation, and possibly even to reproach for previous negligence The results of this careful survey of rheumatic disease will thus bring little practical help in the solution of the problems involved If some doubt has been thrown on the evil portent of such well-established bogeys as tonsillitis and damp houses, a new source of anxiety has been raised It would be unsafe to belittle the value of even slight indications of a way to prevent a disease whose sequelæ may be so severe, but the evidence is happily not sufficient at present to impose the boredom of quarantine on the patient during the long recumbent period which modern treatment exacts

The ingenuity and tact shown by the group of workers conducting this investigation in devising and carrying out inquiries as to family incidence, association with sore-throat, and with various social and housing conditions deserved a more dramatic outcome The inquiry has given provisional answers to many interesting questions, even if it has failed to give any clear view of the lines on which prevention should be sought We must reluctantly agree with the statement made by the Medical Research Council in a preface to the report—that it seems improbable that much further progress can be made until the causative agent of acute rheumatism is identified

MEDICAL RESEARCH IN DANGER

THE Dogs (Protection) Bill, now in print and awaiting its chance of discussion in the House of Commons. is framed in language identical with that of Lord Banbury's Bill rejected in 1925 It proposes that it shall be " unlawful to perform any experiment of a nature calculated to give pain or disease to any dog for any purpose whatsoever, either with or without anæsthetics," and that no such experiments shall be licensed If these proposals were to become law, they would place an insuperable and permanent barrier across some of the chief paths of medical and veterinary research Evidently support for the Bill is being canvassed by means of the old prejudices, and is based upon the old misunderstandings and distortions of the truth It is therefore necessary to repeat once again what has been said before in opposition Many supporters of the Bill undoubtedly think of vivisection as the dissection of a living animal while it is fully conscious of pain , they undoubtedly believe that vivisection in this sense can be, and is, freely practised by medical research workers without restraint under the existing law , they are convinced that fresh legislation is essential in order to protect live dogs from the callous and inhuman infliction of pain On no other basis can anyone explain the statements made in support of the Bill.

---

[1] Bristol Medico-Chirurgical Journal, 1926, vol. xliii., p 96.

The petition to be addressed to Parliament by the National Canine Defence League, with which the Royal Society for the Prevention of Cruelty to Animals is not associated, expresses the opinion that "the dog has of late years been specially selected by vivisectors for extensive and peculiarly revolting and painful experimentation.' The same petition speaks of "demonstrations of a prolonged and agonising nature before classes of students." Sir THEODORE COOK, in a letter in the *Times* of March 7th, recalls the fact that on the back of the entry forms of Cruft's Dog Show was printed an imaginary picture representing an operation performed in France about 100 years ago by a man who died in 1855, beneath the picture was displayed the following sentence: "209,014 experiments on living animals were performed during 1925, many of these being upon dogs." Obviously, as SIR THEODORE COOK observes, the uninstructed reader is intended to infer that operations of the kind illustrated in the picture are constantly happening in England to-day. He asks whether Lord BANBURY or Sir ROBERT GOWER knew of any instances of dogs suffering severe pain after recovery from anæsthetics which were not put to death as humanely as the 28,565 dogs destroyed in the Battersea Dogs Home during the same year. We look in vain in all the mass of antivivisectionist propaganda for any fair admission of the extent to which dogs are protected by the existing law, or of the measures taken (under strict Home Office regulation and inspection) to prevent the infliction of pain. Nothing is said of the elaborate precautions which govern the licensing of the research worker, of the substantial safeguard which insists that his application for a licence shall be signed and countersigned by responsible authorities, of the special certificate which is required if feeding experiments or inoculations are to be done, or of the fact that 95 per cent. of the total number of so-called vivisections come within the class covered by this special certificate. Nothing is said of the fundamental restrictions imposed by the Cruelty to Animals Act of 1876, or of the further restrictions made by the Home Office thereafter. Nothing is said either of the additional safeguards (under Section 5 of the Act) whereby experiments on a dog or a cat are even more stringently regulated. Nothing, finally, is said of the profound benefits to the human race which have resulted from the carefully restricted and officially supervised employment of experiments upon animals in the alleviation of human pain and the cure and prevention of human disease. Information in this respect has been issued in publications more accessible to the medical profession than to the general public. Of the technical details of that information the supporters of the Bill may naturally be ignorant, but there is one aspect of experiments upon animals of which every dog-lover should know. The study of distemper may not only help us to understand and repel certain obscure diseases from which mankind suffers, it also holds out the reasonable prospect that, sooner or later, a great menace may be removed from the canine species. The so-called Dogs (Protection) Bill will bar the advance of science towards the finding of a remedy. It may not unfairly be given the title of the Dogs (Continuance of Distemper) Bill.

Distemper is but one of many problems for the research worker, but what is the attitude of the supporters of the Bill towards it? Their avowed purpose is the total prohibition of all experiments which may promote the cure and prevention of this disease. SIR THEODORE COOK quotes the chairman of an antivivisectionist meeting held last January as having said that the Field Distemper Council had spent three years "in torturing dogs in the most abominable manner." If this were so, why did not the Royal Society for the Prevention of Cruelty to Animals, which seems itself to be concentrating upon a merely antivivisectionist policy, prosecute the offenders to conviction? In the debate on Lord Banbury's Bill in 1925 Lord LAMBOURNE, who supported the Bill, found it necessary to concede that the Bill might be amended so as to make an exception in favour of distemper experiments. Logic we have learned not to expect in the discussion of this subject, but, if distemper experiments are admitted to be unobjectionable, what becomes of the principle of the Bill?

Annotations.

"Ne quid nimis."

THE LISTER DOCUMENTS

DURING the forthcoming Lister centenary celebrations the cabinet containing Lord Lister's instruments, manuscripts, diplomas, and other papers, which occupies a position of honour in Room I of the Museum of the Royal College of Surgeons of England will be a centre of peculiar interest. A noble piece of furniture, the cabinet was the late Sir Rickman Godlee's tribute to the memory of his illustrious uncle. In it behind glass are displayed Lister's instruments and the same collection is continued in another case against the neighbouring wall, which forms a companion collection to the relics of John Hunter in a similar museum case close by. Lister's documents, however, are only partially visible to the public eye, and a number of them, beautifully bound and cared for by his nephew, are locked up in the cabinet drawers. Very interesting among the latter are a number of diagrams of bacteria and general pathology, and also the rolls of common paper, some half-dozen in number, on which over 40 years ago Lister caused a horse, a dog, and a rabbit to place on record the relative pressures of blood in systole and diastole. The elaborate conclusions which he then reached are fully set out in Vol. III. of his "Common Place Book," a work in four volumes here preserved behind a glass door. These books contain the record of the successive experiments in which the great surgeon engaged. They are largely in the handwriting of Lady Lister, who laboured with devotion in her husband's behalf till death cut her off, sadly and suddenly, when the pair were on their travels in March, 1893. Sir Rickman Godlee, in his biography of Lister, has painted a vivid picture of the manner in which these manuscripts were written, often long after midnight, owing to Lister's unwillingness that anything should be set on record till he himself felt sure of it. The illustrations, almost all by the investigator, are fine examples of delicate draughtsmanship, and many who see them will be surprised to learn that he was an anatomical artist of such a high order. The most important volume in the collection under discussion is without doubt the slim folio labelled by Godlee "Notes and Drawings: Suppuration. Lister. 1851-1907." This is the very scripture of Listerism, a treasure beyond price.

Of the other MSS. in the collection there may be mentioned also five letters from Pasteur, in one of which the famous Frenchman speaks of having heard dimly during many years of his English colleague's special investigations and testifies to his own interest in them. He writes as a sick man, his head hanging painfully in sympathy with his semi-paralysed side. The originals of Lister's principal courses of lectures in Glasgow, Edinburgh and King's College are also here, together with five folios containing complimentary addresses signed by the greatest names in science and medicine. The degrees and diplomas alone number some 36 Unlike John Hunter, unlike Shakespeare himself, this mighty pioneer of modern methods in surgery has been "documented" to perfection None of his manuscripts seem to be missing, and all are religiously cared for and preserved

CAPILLARY PERMEABILITY

THAT the capillary wall is normally in a condition of delicately adjusted differential permeability follows from the facts that the volume of the blood is kept constant, and that the nutrition and excretion of the tissues are adequately performed The normal endothelial cell lets water through freely and, as far as we know, offers only a partial obstacle to simple molecules of dissolved substances On the other hand, it is nearly impermeable to proteins, and it is changes in this quality which have for long been familiar, transudates contain little coagulable protein, while exudates contain much, and the amount of proteid is a guide to the permeability In more recent times evidence has accumulated that gross alterations in permeability may affect the volume of the circulating blood, chlorosis is (or perhaps we should now say "was") presumably essentially an error in the mechanism which normally keeps a certain amount of the free fluids of the body inside the blood-vessels and leaves the rest (a variable quantity) outside There are more satisfactory reasons for believing that the depletion of the blood volume in secondary shock is directly due to the increased permeability of the endothelial cells caused by the products of tissue destruction, and in particular by histamine and histamine-like bodies The efficacy of histamine in producing this change locally is beautifully demonstrated by pricking through a drop of a highly dilute solution into the skin; a wheal appears almost at once To find out more about this elusive mechanism and how it is affected in disease is evidently desirable and several explorations along different lines have recently been made We have already drawn attention[1] to the series of papers which have been published in *Heart* by Sir Thomas Lewis and his co-workers at University College Hospital on the reaction of the skin to injury and their conclusion that the production of a local œdema with the formation of wheals is in the main due to the setting free of histamine (or some similar body with a like action) from the tissues injured by the provocative stimulus Everyone reacts in much the same way, but the amount of rubbing which is necessary to evoke the reaction varies so much in different people that those who respond most easily may not unreasonably be said to have a disease—dermographia Parallel inquiries on rather more complicated lines have been made by Dr W F Petersen of Chicago[2] who seeks to obtain some quantitative measure of what may be termed the inflammability of the skin in the manner of Gansslen by putting on a standard cantharidin plaster, observing the time taken for a blister to form and then determining the percentage of proteins in the blister fluid, and comparing it with the percentage in the blood The ratio blister protein/serum protein gives the "permeability index," and this ratio divided by the blistering time in hours brings the inflammatory vascular response into relation with the permeability The method obviously measures a very complex process which it cannot completely dissect into its components, but Dr Petersen and his colleagues have obtained results which suggest that it will prove informative Thus in general, capillary permeability varies inversely with blistering time as one would expect But in decompensated arterio-sclerosis high permeability may be found with a prolonged blistering time, which is interpreted as spasm of the arterioles with a damaged endothelium On the other hand, Graves's disease shows always a short blister time, and the permeability index may vary a good deal In skin diseases such as dermatitis herpetiformis and eczema, there is everywhere a short blistering time, and the percentage of protein in the blister fluid is nearly as high as in the blood serum instead of about three-quarters as much

THE LATE SIR FELIX SEMON

WE have received from Dr Emil Mayer, the well-known American laryngologist, a letter with reference to the autobiography of Sir Felix Semon, which was reviewed recently in our columns (THE LANCET, 1926, ii., 959) The purport of the letter is to call attention to certain matters omitted in the autobiography and not added by the editor, Dr H C. Semon, who wishes that attention should be called in medical circles to the circumstances Both the autobiography and the various obituary articles which followed upon Sir Felix Semon's death alluded to the splendid work done by him when he founded the *Internationales Centralblatt fur Laryngologie* in 1884, and Dr. Mayer, one of the first collaborators in this work, describes the machinery adopted, explaining why for business reasons it was printed in the German language It was at one time projected that publication should appear simultaneously in German, French, and English, but on pecuniary grounds, although collaboration was gratuitous, this ambitious design was dropped. Prof Mayer writes —

"With his passion for order, Semon issued a prospectus for the new journal and the plan made then was strictly adhered to during the entire 25 years in which he was editor-in-chief It was to be an index-medicus as complete as possible, under the direct editorship of the one chosen to represent his country, who signed his own name to each contribution noticed The collaborator used his own judgment as to the length of his abstract Facts known to laryngologists in articles written for the information of general practitioners were marked 'nothing new' When comment was deemed advisable by the collaborator it was added in brackets It is of interest to note that writers approved of this method of a 'chiel amang ye takin' notes,' and frequently expressed their appreciation of the criticism saying that they were thus made more careful in making statements In the 16 years of his connexion with the *Centralblatt*, this writer knows of no single complaint of unfairness in the comments At the end of the year a summary of papers abstracted was published giving the number from each country America with its 200 monthly journals always headed the list Reports of the transactions of special societies and reviews of new books were also part of the duties of the co-editor It was of the *Centralblatt* that Sir Felix said 'Journals of reference exist in order that the reading public should know of articles published presenting a resumé of their contents, but not to make the reading of the originals unessential' After 25 years of editorship, Sir Felix could truly say that the Journal had become the centre of the interests of laryngology throughout the world"

Dr Mayer's connexion with the *Centralblatt*, we learn from his letter, began by association with the first American editor, Prof Lefferts, in 1898, and when he had been a co partner in the scheme for ten years he conceived the idea that the twenty-fifth anniversary of the founding of the symposium would be a fitting opportunity for all associated with the work to present the founder with a lasting memento of the respect and the loyalty of his colleagues

"I procured a list" he writes, 'of all past and present collaborators and sent a confidential letter to each, asking if they approved, that each send me $5 to procure a suitable gift to the man we revered as chief editor The responses were prompt and within a short time letters warmly endorsing the project were sent me with the amount requested by 35 of the co-editors, including the publisher, who was permitted to participate at his own request The choice of the memento was that of a silver box of the exact size and shape of a bound volume of the *Centralblatt*, the outer lid being an exact copy of the style and wording of a cover of the monthly number, its wording transposed to fit the purpose The silver box was made by Tiffany and Company, of New

To the Editor
SIR FELIX SEMON
London
In love and respect, as a token of their appreciation of his highly valued services in the cause of Laryngology and in grateful recollection of the manifold courtesies extended by him to each and every one of them.
Berlin 1909
Published by August Hirschwald
N W Unter den Linden 68

This beautiful memento came as a complete surprise to Sir Felix and was most joyfully and gratefully received by him He stated that he would always cherish it and that it would be kept in his family for all time ”

The presentation was made without knowledge that it synchronised with Sir Felix Semon's retirement, while the episodes connected with the attitude of his successor need no repetition in these columns The attempt under the evil influence of militarism to deprive Sir Felix Semon of his international reputation as the founder of the *Centralblatt* served only to enhance that reputation among those who consider that science does not acknowledge geographical boundaries

BENIGN ADENOMA OF THE KIDNEY

ACCORDING to Dr E Starr Judd and Dr Harold E Simon,[1] who report an illustrative case observed by them at the Mayo Clinic, and give a review of the literature, small benign adenomata of the kidney are not uncommonly found at autopsy Their size varies from a few millimetres to 3 or 4 cm in diameter, they are frequently multiple, and they may be found in one or both kidneys, but it is unusual for them to attain such a size as to cause symptoms of any severity Three histological types of benign adenoma of the kidney may be described The papillary form is the most common and is found in its purest and most elementary form in the smaller tumours This type of structure also predominates in the larger tumours, in which, however, it is usually combined with one or both of the other types The second type which is the next most frequent is the tubular or canalicular While the tubules differ in character and appearance in the different tumours they are of fairly uniform appearance in a given case The connective tissue separating them is usually scanty and glomeruli are not found The third type is the alveolar adenoma described by J Albarran, composed of lobules of alveoli, whose cells often have a high fat content, giving them a vesicular appearance Dr Judd and Dr Simon have little doubt that these tumours arise from the renal parenchyma, and though their relationship to malignant growths of the kidney has not been established, it is possible that they may become malignant The present case was that of a woman, aged 51, who had suffered from intermittent attacks of pain and hæmaturia for the last 11 years At first the attacks had been at intervals of from two to three months, but recently had become more frequent For several years she had noticed a mass in the right side of the abdomen, and lately it had increased in size Examination showed a large mass extending from the right costal margin to the crest of the ilium and across the middle line of the abdomen Cystoscopy showed a normal bladder Ureteral catheters were passed without difficulty, and the differential phenol-sulphonephthalein test yielded about one-third the normal return from the right side and a normal return from the left The left pyelogram was negative, while the pyelogram of the right pelvis showed a rather indistinct outline A diagnosis of right renal tumour was made, and on exploratory incision an enormous tumour was found arising from, and intimately associated with, the right kidney Nephrectomy was performed and the patient made a rapid recovery. Histologically the tumour was found to consist of papillary and tubular structures in about equal proportions

SHOCK AND COLLAPSE

IN his Hunterian Lecture to the Royal College of Surgeons of England on Feb 28th Mr Zachary Cope performed a salutary task in drawing attention to the vague state of the common understanding of the terms “ shock ” and “ collapse ” He attempted a more precise definition of the terms, and at the same time justly emphasised the variability of the clinical manifestations of these states. In particular he drew attention to the importance of the slow pulse-rate which sometimes accompanies shock and has often misled observers into a sense of false security A slow pulse-rate is a grave sign if associated with a low blood pressure, estimation of which is easily made but often neglected Mr. Cope showed, however, that even lowering of the blood pressure is not a constant sign The late war afforded all too many opportunities for observing shock, and the stimulus of war needs provided most of the scientific evidence on which our knowledge of shock is based. Mr Cope now seeks to apply the principles thus learnt to the fuller understanding of the surgical emergencies of civil life, especially perforations of a gastric or duodenal ulcer He gave point to his remarks by quoting the case of a patient who was operated upon so quickly after the perforation of a duodenal ulcer that the combined shocks of perforation and of operation caused his death The mysteries of “ latent shock ” and “ delayed shock ” were intensely investigated during the war, notably by Dale, Bayliss, and Cannon, but the theories then formulated have not provided a final solution Mr Cope's plea for recognition of the importance of the clinical observation of surgical emergencies gained much force from the actual cases which he described He did not, for the present, enter upon discussion of the principles to be observed in treating the condition of shock, but this can only follow on further elucidation of the factors that are at work in its production More research, in fact, by physiologist and clinician is still required

CHRONIC ARTHRITIS

IN a paper[1] based on the critical study of 1100 cases R Pemberton and E G Peirce give a more hopeful opinion of the treatment of chronic arthritis than is usually held Their patients comprised 400 soldiers on active service and 700 civilians, more than two-thirds of the latter being women Treatment included removal of infected foci, dietetic and physiotherapeutic measures, and injections of non-specific protein and specific vaccine Each case was treated on its merits and no attempt was made to exploit any particular line of treatment Of the army cases

[1] Amer Jour of Med Sci , 1927, No 1, clxxiii , 31

77 per cent recovered completely and only 4 per cent were unimproved Of the civilian cases, which included the more advanced types, 24 per cent. recovered completely and 9 per cent were unimproved Demonstrable foci of infection were present in 70 per cent, and in others foci had been removed previously. Dental infection was present in 54 per cent. and tonsillar infection in 31 per cent, urogenital infections played but a small part Mere removal of foci of infection was insufficient to cause improvement In some cases successive focal infections caused by different organisms occurred whilst the patients were under treatment, and in other cases tissues such as the tonsil, harbouring foci, were seen to become nearly or quite normal following improvement in the arthritis from a well-planned regimen This suggests that focal infection may often be the result of a systemic imbalance as well as the cause of it Many of the cases could be classified into the proliferative and degenerative types of Nichols and Richardson, which correspond roughly to the rheumatoid arthritis and osteo-arthritis of English authors, but many could not be classified It would have been more helpful if a closer classification had been attempted, for a study of the age of onset, sex, and joints involved suggests that most of the cases were of the infective fibro-arthritic type involving only one or two joints, and it is the general experience that this type responds very well to treatment and that complete cure can be obtained It is doubtful if joints attacked by true rheumatoid arthritis can ever be restored to normal, and the same is true of osteo-arthritis Although Pemberton and Peirce consider that there is evidence of a common physiological disturbance underlying several clinical varieties of the disease it is perhaps more probable that under the heading of chronic arthritis are included several distinct diseases differing in their ætiology, pathological features, and response to treatment There is but little resemblance between the rheumatoid arthritis of young women with its profound metabolic disturbances, the osteo-arthritis of the hip in elderly persons, and the infective arthritis of the knee or wrist which attacks mainly the soft structures without bony involvement More progress may be made when these types can be more clearly differentiated and separately studied

NATURE OF RABIES AND THE NEGRI BODIES

Ever since the first description of the intracellular formations now universally known as Negri bodies, these bodies, whose appearance in the large cells of the central nervous system and in particular in those of the cornu ammonis is the chief histological finding in hydrophobia, have been of acute interest to pathologists An unending argument has raged over their nature, the partisans of one theory declaring them to be parasites, whilst their opponents maintain that they are nothing more than the results of degeneration Both sides, however, have agreed that their appearance is characteristic and pathognomonic of this disease The latest contribution to the subject comes from C Levaditi, S Nicolau, and Mlle R Schoen of the Pasteur Institute[1] These workers have already carried out very extensive researches into encephalitis lethargica and herpes, and the spontaneous (microsporidial) encephalitis of rabbits, and it has been long held by Levaditi that the first two of these diseases have much in common with vaccinia, poliomyelitis, and rabies, he believes that all are due to filtrable viruses and that all may show, under different conditions, affinities for both the epidermis and the central nervous system Turning his attention now to rabies this fruitful investigator has attacked the problem of the nature of the virus and produced a voluminous piece of work After pointing to the tinctorial and morphological similarities between the Negri bodies and the cysts of certain microsporidia, the theory is developed that the Negri bodies represent a stage—pansporoblasts—in the life-history of a protozoal parasite, the units of which at other times in its life-history are extremely small and capable of traversing bacterial filters It is in this spore stage that the virus is eliminated by the salivary glands of a rabid animal and infects the bitten subject The parasite reaches the central nervous system by means of the nerve trunks and pullulates within the cells of the brain It must be conceived that all portions of the central nervous system become infected, since all are virulent, but that the development of the organism is more favoured in certain sites than in others, thus the medulla and pons are more intensely invaded and show the infection at an earlier stage than do other parts of the brain, and their cells, moreover, undergo histological degeneration; whereas the cortex cerebri, Purkinje cells, and the cells of the cornu ammonis, though infected, retain their histological integrity and show little or no degeneration These are the very sites in which the Negri bodies develop, an apparent paradox which is explained by Levaditi and his colleagues by the assumption that it is only in the more resistant cells, whose morphological and physiological integrity is preserved for the longest time, that the pansporoblasts are formed, only the vegetative phase of the organism existing where its destructive effects are greater

This thesis would give a plausible explanation to the disturbing fact, which has so often been used as an argument against the acceptance of the living nature of the Negri bodies, of their absence in *virus fixe*—the brains of rabbits succumbing to the inoculation of material of artificially exalted virulence, and hence presumably most rich in the infecting agent If Levaditi's view is correct the *virus fixe* produces so profound and progressive an infection that the conditions of cell resistance, necessary for the production of pansporoblasts, are never realised Numerous experiments are cited which give force to this argument It has been shown in the progressive exaltation of virulence which goes to the making of *virus fixe* that, as the incubation period shortens, the size and number of Negri bodies diminish pari passu until when the stage of maximum virulence is reached—i e, the *virus fixe* of Pasteur—they can no longer be found And it has also been shown in this connexion that various strains of street virus differ greatly, as judged by the criterion of the Negri bodies, in their ability to become converted into *virus fixe* In some this is readily accomplished in a few passages, but in others it seems impossible to carry out The transformation into *virus fixe* is regarded by these authors as a mutation (the right to use this term may be questioned, as from their experiments the transformation is obviously gradual), which results in a definite loss on the part of the organism of the ability to reproduce the pansporoblasts stage; the change, at all events, is irreversible and by no experimental manœuvres can this virus be made to give rise to Negri bodies In the view of Levaditi and his colleagues this mutation is associated with an increased affinity of the virus for the central nervous system It therefore follows that the material used in the antirabic inoculation of man is essentially of a highly virulent character but the lack of danger in its use is believed to be due to the dilution of the germs present in the preparations, and to the fact that the tissue into which the virus is introduced is little favourable for its further development in this newly acquired specialised form

The general view put forward is by no means new, as the authors admit, while many claims towards the elucidation of the life-history of the rabies organism have from time to time been made Noguchi at one time announced its successful cultivation by the procedures employed in the investigation of the globoid bodies of polio myelitis, and Y. Manouelian and J. Viala[2] claim to have demonstrated the microsporidial characters of the virus and certain of its evolutive phases in the tissues. Levaditi and his collaborators have put forward a reasoned hypothesis which explains many of the difficulties in the way of the general acceptance of the Negri bodies as representing a visible phase of the parasite and their view is supported by an abundance of ingenious experimental work. They propose for the organism the name of *Glugea lyssæ*. Whilst themselves convinced that their theory is correct and offering serious evidence in support thereof, they do not pretend to have furnished proof and avow their complete ignorance of the larger part of the life-cycle of the organism of which they claim to have demonstrated a part.

SCIATIC PAIN

THE Lady Jones Lecture of the University of Liverpool was delivered on Thursday, March 10th, in the Medical School of the University by Dr. Vittorio Putti, Professor at the Rizzoli Orthopædic Institution, Bologna, and formed a clear and in some directions novel disquisition upon the pathogenesis and treatment of sciatica. He pointed out that in the middle of the eighteenth century Domenico Cotunio was the first to recognise that a clinical entity often had to be dealt with under the name of sciatica, the next step towards diagnosis being taken by Charcot who drew attention to the association of sciatica with vertebral deformity and Brissot who, working on the same lines, introduced the term sciatic scoliosis. But regarding sciatica as a symptom, save when the pain is due to direct involvement of the nerve by known pathological processes, he insisted that such sciaticas were not to be confused with rheumatic sciatica—so called from its assumed causation; and the ætiology of this common form he proceeded to discuss entitling it "essential sciatica." It was, he held, being cleared up by modern inquiry, and while there was no difference between pain originating in the spinal cord, in the peripheral nerves or in the sympathetic, the patients' descriptions, which had to be relied upon, introduced an uncertain diagnosis. Hence he made no critical examination of the theories in regard to localisation of pain, but concentrated on that factor in the causation which had attracted so much recent attention—namely, the vertebral element. The idea is not new that a nerve may be irritated in the canal or foramen which it traverses. Long ago it was recognised that many types of trigeminal neuralgia, facial, supra scapular and Arnold's occipital nerve neuralgia as well as ulnar and radial neuralgias, are brought about by mechanical irritation of the nerve trunk in the bony foramina or osteoperiosteal canals. Sicard, Prof. Putti reminded his audience, renamed these conditions "nervodocitis," but Goldthwait, an orthopædic surgeon in Boston, U.S.A., made the first investigation of the whole problem from the anatomical and mechanical aspects upon which mud modern work is founded. A striking result of that work, however, proved fruitless. In the intervertebral foramen between the fifth lumbar and the first sacral runs the fifth root of the lumbro-sacral plexus, a root which is the principal constituent of the sciatic nerve.

It was conjectured that removal of the transverse process of the fifth lumbar vertebra might bring relief, but no such fortunate result occurred. But the lecturer pointed out that none the less cases of sciatica show one constant factor, the association of pain with anatomical alterations or functional disturbance of the lumbar spine. He described his personal investigations, especially with the assistance of X rays into various deformities of the spine, a study which he had commenced 15 years ago, when he published some of his results. He warned his audience that investigation of the intervertebral foramina did not tell the whole story, for as well as the vertebral canal the funiculus must be considered. He summarised the latest work of Bonniot and Forestier by pointing out that "the fourth and fifth lumbar nerves possess the longest funicular portion of those which constitute the lumbo-sacral plexus—i.e., they take the longest course through intervertebral foramina, while the funicular portion of these nerves, unlike the intra spinal portion, does not lie within the arachnoid, but is only clothed by dura mater and is not bathed in cerebro-spinal fluid. Around the veniculous plexus there is a very rich venous plexus which is much influenced by mechanical conditions outside the funiculus. The absence of arachnoid, and therefore of a protective layer of fluid, exposes the funiculus to outside mechanical influences such as do not affect the root, while the surrounding venous plexus puts it at the mercy of any congestion and stasis that may occur in the neighbourhood from many causes." Here, then, is the critical region, and it is here that the importance of X ray examination is so obvious, but only if a clear interpretation can be put upon the evidence. No progress, Prof. Putti thinks, could have been made in the elucidation of many obscure problems, if X rays had not convinced surgeons that idiopathic or "essential sciatica" is synonymous with spinal arthritis. In the latter half of his lecture he supported the thesis with schematic figures and original radiograms.

ULTRA-VIOLET RADIATION AND THE EYE.

IN an article in the *British Journal of Ophthalmology* for February, entitled An Ophthalmic Radiation Lamp, with a Note on its Diagnostic and Therapeutic Applications, Mr. W. S. Duke-Elder of the National Institute of Medical Research and the Ultra-violet Clinic at Moorfields Hospital, issues a warning which is probably needed. It cannot be over-emphasised, he says, that despite the deplorably unfortunate attention of the lay press, ultra-violet light is not a universal panacea. The phototherapist of the eye should certainly be a competent physicist as well as a competent ophthalmologist, since dangers as well as benefits may follow the use of the new method. Suitable apparatus can be used with good effect in cases of "blepharitis, chronic conjunctivitis, corneal ulcers, recurrent, marginal, and hypopyon ulcers, recent corneal opacities, phlyctenular keratitis, tuberculous keratitis acne, and some cases of episcleritis." All these, however, are diseases of the external coat of the eye or its adnexa, and Mr. Duke-Elder is of the opinion that local phototherapy is contra-indicated in diseases of the inner eye, with the exception of those cases of iritis showing nodules on the anterior surface of the iris. The chief danger is that the incidence of radiant energy of any wave-length on the lens may be a factor in the causation of cataract. The heat rays are the most dangerous in this respect, but Mr. Duke-Elder believes that ultra-violet light may also be hurtful if it is focused on a lens predisposed to pathological change. The "treatment" of cataract by ultra-violet light has, he says, been carried out in some quarters; but "those results which have come under my observation might lead me to suggest it as a method for the maturation of cataract." The sentence with which he closes we will quote in full for it should be pondered by any who are inclined to dally with non-operative cures for cataract. "The coagulation of protein is an irreversible chemical change. It seems not unreasonable to hope that in the future when our knowledge of this change and the factors causing it has been more fully developed, it may be possible to prevent its incidence or to delay or arrest its progress, but to set out to 'cure' cataract in the sense used above by any means, medical or physical, is quite unjustified." Mr. Duke-Elder's paper incidentally lends support to our plea (THE LANCET, Feb 26th, p 450) that manufacturers of ultra-violet apparatus should be discouraged from the unrestricted sale of their lamps to the public at large.

THE TRUE TEMPERANCE ASSOCIATION

THE annual meeting of this Association was held at the Caxton Hall, Westminster, on Monday, Feb 28th, when the principal medical speaker was Dr Robert Hutchison Dr Hutchison in an interesting speech put forward what he suggested to be the healthy point of view of the temperance question viewed from the angle of the great majority of medical men These, he considered, believed from observation that patients whose habits in respect of drinking were moderate, proved no more subject to chronic disease and no more susceptible to acute illness than their teetotal patients He alluded to the difficulty of proving this common impression by statistics, and reminded the audience that the figures to be obtained from life assurance companies, some of whom did and several of whom did not accept proposals from other than teetotallers, were vitiated by the fact that the bulk of the companies making no such proviso included in their records the excessive drinker as well as the moderate drinker, while no one doubted that excessive drinking is injurious to health He referred his hearers to Prof Raymond Pearl's statistical inquiry contained in a book entitled "Alcohol and Longevity" (New York Alfred A Knopf, 1926) for definite figures which were the result of an investigation into over 5000 individuals belonging to the working class in Baltimore These figures, he said, were in his opinion as definite as any that would ever be obtained, and Prof Pearl's conclusion from them was that the moderate drinkers were just as long lived, and as a matter of fact rather longer lived than the non-drinkers The speaker's deliberate personal point of view was, he said, that the occasional and moderate use of alcohol is, from a strictly health point of view, beneficial rather than otherwise Whether regarded as food or medicine, taken in moderation and at the end of a working day, it soothes the nervous system and helps digestion in many persons Further, the moderate use of alcohol he considered to promote social recreation, which is so valuable for health, a use which is largely neutralised by the unattractive, not to say disgusting, environment of the usual public-house, where quick drinking is encouraged and where also it is often very difficult to get food to accompany the alcohol Dr Hutchison said that he was speaking here as a supporter of the People's Refreshment House Association and of Trust Houses, whose object was to improve the standard and class of the public-house in England, and he concluded by referring amusingly to the "Machiavellian intention" of teetotallers to keep public-houses in their present state, when they undoubtedly form an argument for abstention

WE have received copies of the newly published Medical and Dental Registers for 1927 and of the Medical and Dental Students Register The total number of persons registered under the Medical Acts from the beginning of registration in 1858 until Jan 1st, 1927, is 100,430 and it is estimated that 52,614 of these remained on the Register on Dec 31st, 1926 The number of names added during the year was 2120, and 46 were restored Against this must be set the removal of 1159 names on evidence of death or under Sections 14, 28, and 29 of the Medical Act The number of names added to the Register during 1926 was smaller than in any year since 1922, but the number of medical students registered rose to 1260, which is higher than at any time since that year As regards the national sources of medical practitioners, it is interesting to note that of those whose names remain on the Register 47 89 per cent are on the English local Register, 31 67 per cent on the Scottish, and 14 86 per cent on the Irish The number of names on the Dental Register for 1927 is 14,395 of which 45 per cent are registered with medical, surgical, or dental qualifications, and 55 per cent under the Dentists Acts (1878 and 1921) A total of 229 dental students was registered during 1926 All three volumes are published for the General Medical Council or the Dental Board by Constable and Co, Ltd.

ABOUT 150 members of the Inter-State Post-Graduate Assembly of North America, accompanied by Dr Charles Mayo, will reach London at the beginning of June, en route for a post-graduate tour of Northern Europe While in London a programme of lectures will be arranged for them, to take place at Dartmouth House, the new building of the English-speaking Union The following hospitals will arrange special programmes during the afternoons · St Bartholomew's Hospital, Westminster Hospital, St Thomas's Hospital, Middle sex Hospital, Charing Cross Hospital, London Hospital, King's College Hospital, Prince of Wales's Hospital, Brompton Hospital for Consumption, Infants Hospital, Vincent-square, Cancer Hospital, National Hospital for Diseases of the Heart, Chelsea Hospital for Women A reception will be given at the house of the Royal Society of Medicine by Sir James Berry, the President, on Friday evening, June 3rd

The Services.

ROYAL NAVAL MEDICAL SERVICE

Surg Lt-Comdr J F Pace to be Surg Comdr

To be Surg Lts J Johnston, J B Patrick, J R C Spicer, and C P Burges

Act. Surg-Lts (D) to be Surg Lts (D) W E L Brigham, S Mawer, L F Fairey, L A Moules, F D Manners, G Baker, L R Armstrong, H M Hill, and W C G Ford

ROYAL ARMY MEDICAL CORPS

ARMY DENTAL CORPS

Capt R H Bebb to be Maj

Temp Lt F Widlake relinquishes his commn.

J M F Whitby to be Temp Lt

Temp Lt W. G Bradbeer, Dental Surg Gen List, to be Lt.

ARMY RESERVE OF OFFICERS

Lt.-Col W B Winkfield having attained the age limit of liability to recall, ceases to belong to the Res of Off

Lt G C F Roe to be Capt

TERRITORIAL ARMY

Capt L P Marshall, late W Yorks R, to be Lt and relinquishes the rank of Capt

ROYAL AIR FORCE

Flying Off H C Patterson relinquishes his short service commission on account of ill-health

Flying Off D Oliver resigns his short service commission

Flight Lt (hon Squadron Leader) F R Humphreys relinquishes his temporary commission on completion of service

Flight Lt N H Medhurst (Capt Army Dental Corps) relinquishes his temp comm on return to Army duty

INDIAN MEDICAL SERVICE

The King has approved the retirement of Lt-Cols D W Sutherland and A Whitmore

The King has approved the retirement of Col C H Bensley and Lt-Col Manmatha Nath Chaudhuri

Lts G M Irvine, G J Joyce, and J S Riddle to be Capts

Bhavani Shanker to be Temp Lt

R A M C AND GUARDS

DIVISION REUNION

It is proposed to hold a reunion of all officers, W O 's, N C O 's, and men of the Royal Army Medical Corps who served with the Guards Division during the late war, and those who have not had particulars should send their names and addresses to Mr J McKeown, late staff-sergeant R A.M.C, No 4 Field Ambulance, 90, Ashurst-road, North Finchley, N 12 The proposed date of the reunion is Saturday, April 23rd

Modern Technique in Treatment.

A Series of Special Articles contributed by invitation, on the Treatment of Medical and Surgical Conditions

CCXIV.—INFLUENZAL PNEUMONIA.[*]

The organisms most frequently associated with lobular pneumonias are *B. influenzæ* streptococci, and pneumococci of various types Besides lobular consolidation the pathological picture may comprise bronchiolitis peribronchial inflammation and abscesses œdema or collapse according to the predominant organism. The treatment of pneumonia resolves itself into providing or enabling the patient to provide sufficient antibodies to overcome the bacteria and their toxins But antibodies are only slowly produced and the patient may succumb to the intoxication before sufficient are present It is true that most patients will get well with simple expectant treatment, by which we mean little more than rest in bed with careful feeding and nursing. But we cannot pick out these patients from the others in whom the immunising response fails and faced with a mortality of 20 to 30 per cent we must ask ourselves whether more direct help cannot be given The only specific treatment available in influenzal pneumonia is with vaccines which are of considerable assistance when injected promptly in adequate doses

Pneumonia should be regarded as an acute medical emergency demanding as prompt action as any surgical emergency. The object of specific treatment is to control the infection before it gets out of hand. Sometimes diagnosis is delayed until signs of consolidation are present, owing to the unfortunate confusion between the disease and one of its manifestations The worst cases often have no recognisable consolidation The early symptoms are so striking that it should be possible to take prompt measures within 24 or at most 48 hours of the onset, and the patient's fate may be decided within the first two days

General Treatment

Detailed instructions must be written down, especially when patients are nursed by unskilled relatives First I would place absolute rest and free ventilation. From the beginning patients must be kept strictly in bed. Most patients object to the use of a bedpan, and unless strict orders are given at the beginning they will get out of bed as long as it is physically possible. Too much effort is caused by routine washings, reaching out for the sputum mug or feeding cup, and sitting up to cough. One garment slit down the middle should be worn and so prevent the exhausting struggle to get night-shirt and vest over the arms and head. Windows should be open night and day and the bed unscreened in the middle of the room. Fresh air is the finest circulatory tonic we possess but it must be used with common sense and the patient must not be exposed to icy draughts of cold air or to glaring sunlight During the initial chilly stages abundant bedclothes and a hot-water bottle are required but when the fever is established one sheet and blanket are sufficient. Gamgee jackets are relics of the days when it was thought that pneumonia was due to cold and therefore should be treated with heat Sponging night and morning should be done as a routine. Tepid water is usually advised, but very hot water at 110° F. by causing dilatation of capillaries is more effective in causing heat loss Additional sponging can be done when the temperature taken four-hourly exceeds 104°.

Diet

The most easily assimilated food is glucose, which has the additional advantages of feeding the heart muscle and preventing acidosis One pound should be dissolved in three pints of water with the juice of two lemons. If this is taken freely over the 24 hours the amount of milk given need not exceed one pint and should be citrated Coffee or tea can be added to some of the feeds. If additional food is required it can be given as albumin water, the whites of two or three eggs in one pint of water, flavoured with a little meat extract. Beef teas have a very small nutritive value and are objectionable on account of the large amount of extractives

The hygiene of the mouth requires constant attention. Dentures must be removed and the mouth wiped out with a rag moistened with a weak watery antiseptic such as listerine before and after food. Washes containing glycerine should not be used. A spray of parolein or chloretone inhalant to the nose adds to the patient's comfort Three grains of calomel at the onset followed by a saline may be given, but thereafter a morning soap-and-water enema will relieve the bowels and prevent distension A simple febrile mixture containing pot. citrate gr. 20, liq. ammon acetatis drachms 4, will aid the action of the skin and kidneys

Vaccine Treatment

A vaccine for use in influenzal pneumonia should contain equal numbers of *B. influenzæ* pneumococci, and streptococci, and be made so far as possible from primary cultures of various strains. For an adult a suitable dose is 100 millions of each organism; for a child of twelve 50 millions and for a child of two or three 10 to 20 millions. Much larger doses can be safely used When such doses are used on the first day of the illness in the majority of cases the temperature falls to normal during the following day and no further treatment is required. With each day's delay such rapid defervescence becomes less likely and the dose may have to be repeated every 24 hours until the temperature falls. When injection is delayed until the fourth or fifth day little can be expected from specific therapy. In a series of 107 consecutive hospital cases the results were as follows:

Day of first injection.	Cases.	Recovered	Died.	Temperature normal in— 24 hours	Temperature normal in— 48 hours.
				%	%
1st	28	28	0	71·4	85·7
2nd	23	22	1	47·8	56·5
3rd	22	20	2	50·0	72·7
4th	20	15	5	30·0	40·0
5th	14	12	2	35·7	63·5
	107	97	10	50·0	65·0

The only death among 51 patients injected during the first two days was that of a young woman admitted with mania who died of pulmonary embolism on the ninth day after the temperature had been normal for five days. Seven out of the ten deaths occurred in patients not injected until the fourth or fifth days, four were complicated respectively with mitral stenosis, advanced pregnancy, meningitis, and asthma, and the three others had considerable albuminuria

The chief obstacle to the use of vaccines has been the fear of a negative phase A negative phase can only occur in a patient who is "sensitised" that is, possesses specific antibodies. During the first few days of pneumonia and other acute infections the patient has no antibodies and is not sensitised, so that a large dose can safely be given Indeed, as much as 5000 to 20 000 million pneumococci have been injected intravenously into pneumonia patients with good results. The very rapid effect obtained suggests that the first action of the vaccine is non-specific, the specific effects being obtained later.

Symptomatic Treatment.

In the early stages relief of pain and sleeplessness is important Leeches when they can be obtained, give quick relief to the pleuritic pain. Antiphlogistine can be kept on for 24 hours and is preferable to linseed poultices, which require frequent disturbance of the patient, but the latter are more easily applied by the unskilled. With either, care must be taken not to embarrass the chest movements. In hospital patients immediate relief can be given by the insertion of 400 to 500 c.cm. of oxygen between the pleural layers with a pneumothorax apparatus. Counter-irritation should not be continued after pain is relieved. Dover's powder (gr. 10) will relieve both pain and sleeplessness. The milder hypnotics are usually ineffective, and when Dover's powder fails to bring sleep omnopon, gr. $\frac{1}{6}$, is better than morphia. In the early stages its use is quite safe in the absence of cyanosis or much bronchial secretion. Paraldehyde is objectionable to take but generally regarded as safe. One to two drachms can be given in very sweet tea or two to three drachms stirred into two ounces of starch paste and given per rectum. In severe cases, with great excitement and struggling, hyoscine hydrobromide, gr. 1/100 to 1/50, is the only drug likely to take effect. In the later stages, when there is cyanosis and much secretion in the tubes, all drugs which cause sleep are unsafe. In such cases atropine will be useful. If gr. 1/100 does not give the desired effect it may be increased up to gr. 1/30. But in the grave cyanotic cases with much respiratory embarrassment ammonium carbonate (gr. 5 every two hours) is a valuable remedy. It may be increased up to gr. 10 hourly for six doses and then after an interval of a few hours the course repeated. Owing to its nauseous taste it should be given in milk. Raising the foot of the bed also helps the drainage of the bronchi.

With early specific treatment, feeding with glucose, rest, and fresh air, much can be done to avoid circulatory failure. The heart can be best helped by food and oxygen and the best food is sugar. With the slightest indication of anoxæmia oxygen should be administered through a rubber catheter passed into the nasopharynx. It is surprising that it is still often administered by the wasteful and futile method of the funnel. There is no evidence that digitalis is of any value for the treatment of heart failure in pneumonia except when auricular fibrillation is present. More can be said for its early use (♏ 10 to 15 three times a day), with the object of retarding the pulse. The heart, however, does not fail because of its rapidity but because of its intoxication. Heart failure does not stand alone, but is part of a general circulatory failure which is as much due to the action of toxins on the medullary centres as upon the heart muscle. In such a condition digitalis can do but little, and the same is true of strychnine, camphor, and caffeine. With a falling blood pressure pituitrin, $\frac{1}{2}$ to 1 c.cm., or adrenalin (1 in 1000), minims 5 to 10, can be injected every six hours, the former is especially useful when there is tympanites. Recently synthetic drugs, such as coramine and cardiazol, have been introduced, and are worthy of trial as analeptics. Alcohol is the most used of all drugs in pneumonia and influenza. There is no scientific reason for its use, which is mainly traditional and due to the popular idea that it is a stimulant. Whilst in the early stages it may remove inhibitions due to pain, counteract restlessness, and induce sleep, its repeated administration helps to increase the degeneration of heart muscle and impairs resistance to infection.

The high mortality from the pneumonias will never be reduced by attempts to treat poisoned organs incapable of response, but only by early diagnosis and prompt measures to prevent intoxication. Expectant treatment in the early stages is apt to be followed by harmful drugging in the later

Professor of Medicine, University of Birmingham.

Special Articles.

THE NUTRITIONAL CONDITION OF THE EAST AFRICAN NATIVE

BY J. L. GILKS, F.R.C.S. EDIN.,
DIRECTOR OF MEDICAL AND SANITARY SERVICES, KENYA,
AND
J. B. ORR, D.S.O., M.C., M.D., D.Sc. GLASG.,
ROWETT INSTITUTE, ABERDEEN.

As the development of East Africa has proceeded there have been increased facilities for collecting information with regard to the physique and general health of the native race. It becomes evident as information on this subject accumulates that some of the conditions of malnutrition and lowered resistance to diseases which are being studied so intensively in Europe and America and are being ascribed to "deficiency" diets and faulty hygiene of modern civilisation, are not uncommon amongst African natives. Indeed, it may be stated here that disease in one form or another appears to be as prevalent among native races as among civilised peoples, and the problems of the prevention of disease are as acute as, and in many respects more difficult than, in Europe and America.

The only reliable data on the incidence of disease are the statistics on native labour employed on railway construction and the admissions to native hospitals. Observations by resident officers in the native reserves, however, seem to show that the diseases which are most prevalent amongst native workers, and in natives admitted to hospital, are also prevalent in the native reserves, so that this data may be taken as giving a more or less accurate indication of the incidence of disease in the native tribes from which the contract labour and hospital cases are drawn.

On the average, the mortality and sickness rate amongst railway construction labour has been in the past as high as in industrial areas in Britain. Thus, of a labour strength of 14,000 employed in the construction of the Uasin Gishu Railway in 1921, the death-rate was 46 per 1000, and the admissions to hospital for a period of six months for which records are available were 2892. The sickness rate has rapidly declined and is still declining. In 1924 the death-rate in native labour on railway construction was only 10.8 per 1000. This decrease is almost certainly due to improvements in the diet and hygienic conditions. The diet was made more varied and more like that consumed by Europeans by decreasing the amount of maize and increasing the amounts of legumes, vegetables, and meat. Even this lower rate—10.8 per 1000—is, however, high for selected men medically examined before being accepted for work. In the British army, the body of men in this country most comparable to the African contract labour, the death-rate in peace-time is only about 2 per 1000.

The Prevalent Diseases.

This high rate of sickness and mortality is not due to "vocational" diseases. Indeed, the diseases which are most prevalent among the native workers appear to be pretty much the same as those most prevalent among the rest of the population. The commonest diseases are those of the respiratory organs. These account for nearly 50 per cent. of the deaths from all causes. A large proportion of the cases are pneumonias. Pulmonary tuberculosis is common. In Mombasa in the years 1922, 1923, and 1924, it was second on the list of causes of adult mortality. The same high incidence of tuberculosis is found in Nairobi.

Ulcers, situated chiefly in the legs—i.e., the parts most liable to abrasion—are very common. In the construction of the Thika-Nyeri Railway, out of a labour strength averaging 4142, the cases of ulcers admitted to hospital numbered 186, and the total number of hospital days required for the cure was 4054 The cases of ulcers which are encountered in the native reserves are frequently of a most severe type, and it is no uncommon thing to find that the ulcerative process has extended to the bone and that the resulting osteomyelitis has led to the formation of extensive sequestra

Dysentery is also common The infection is not usually amœbic, and bacteriological examination does not reveal the presence of the bacillus of dysentery. In 1925, out of a total of 66 cases examined at the laboratory in Nairobi, only six instances of infection with Shiga bacillus were detected and none with Flexner A striking feature of dysentery among labour on works or estates is the frequency with which the disease appears among newly joined recruits A parallel is found in the incidence of pneumonia among labour employed in the mines in South Africa It is the newly joined men who go down most frequently. Those of longer standing, who incidentally have been fed for a longer period on a carefully adjusted diet, are relatively immune In this connexion it is interesting to note that in the Katanga mines in the Belgian Congo it is the custom to draft newly recruited labour to a special camp where the men are fed properly to put them into good condition before they are allowed to work

Cases of cancer are found in the native reserves There are no figures to show whether or not it is as common amongst the natives as it is in Europe, as only a very small proportion of natives suffering from disease are seen by medical officers It can be definitely stated, however, that cancer is by no means a rare disease The myth that the primitive races of Africa do not suffer from cancer has been exploded years ago

The Dietary

The foregoing would indicate that the Kenya native is unduly susceptible to disease The next point to consider is whether his dietary is such as should supply him with the requirements, as recognised to-day, for a healthy nutritional condition The diets of the various tribes vary as widely as do their languages, and vary with their environment as well as with their particular customs and prejudices Some have a diet almost as mixed as that of the European, and in the opinions of those best competent to judge, these were the most efficient carriers during the war Among these may be mentioned the Kavirondo from the shore of the Victoria Nyanza, from whom is drawn what is widely considered to be the best labour in the colony. On the other hand, the tribes of the slopes of Mount Kenya live almost exclusively on a cereal diet Little or no meat is eaten, and such as is consumed is largely on account of superstition or religion, indicating possibly a physiological craving It is the elders who profit, as a rule, from the ceremonial meat-eating The young men of the warrior class develop at intervals a meat-hunger, in fact there is a verb in the Kikuyu language indicating to become hungry for meat A group will combine to purchase or obtain a bullock The party adjourns to a suitable place where the bullock is slaughtered and eaten on the spot Afterwards a period of abstinence from meat follows Absence of meat from the dietary does not come about as a result of preference Cattle and goats are valuable possessions, chiefly used in the purchase of wives, they cannot therefore be slaughtered in a light-hearted way for food Every advantage is taken when an animal dies from natural causes The carcass is regarded as a welcome addition to the menu and is disposed of accordingly The result is reflected in the large total of cases of anthrax, which is returned every year in the official medical statistics The physique of the Mount Kenya tribes is far from good and it has long been considered that a dietary deficiency is at the root of the unsatisfactory condition which prevails

Near neighbours of the vegetarians referred to above are the Masai, formerly the terror of East Africa The Masai in his natural state lives almost entirely on meat, milk, and blood The last is drunk fresh As a labour force the Masai are negligible Their interest is in cattle and nothing else, and apart from engaging as herdsmen they do not enlist for work Not much is known as yet as to the medical or nutritional condition of the Masai who, perforce, adhere to their nomadic habits, but it has been reported that rheumatism and constipation are common among them. There are indications that the hitherto exclusively protein diet is being added to by carbohydrate in the form of maize meal, which is being obtained by purchase or barter

The foregoing brief and incomplete sketch of the dietary habits of tribes in Kenya must be supplemented by allusions to customs which in themselves may indicate that deficiencies occur in connexion with the mineral constituents of the food. All over the country occur salt licks to which are driven the cattle after sojourn for more or less extended periods in other grazing areas It is not, however, only the cattle who consume the earth found at these licks Human beings take their quota, either eating it as it is found or steeping it in water and drinking the supernatant liquid, or using it to prepare food The custom is not so largely followed as formerly The earth is still seen exposed for sale in the market-places for administration to cattle or goats, but for humans its use is being largely replaced by the raw soda produced at Lake Magadi The children in a Kikuyu market-place purchase their measure of Magadi soda, which they consume with the same gusto as do English children their pennyworth of sweets at a fair

The Kavirondo add cow's urine to their milk before consuming it. A similar custom obtains among other African tribes One is reminded of animals which, when deprived of minerals, drink the urine of each other.

Disease and Primitive Methods of Life

The African native is thus by no means the "noble savage" that he is frequently supposed to be He is prone to infectious disease and he is too frequently an individual of poor physique. The infantile death-rate, where it has been worked out in purely native areas, is somewhere between 400 and 500 per 1000. Granted that the native babies are given artificial food at a very early age in the shape of gruel or chewed-up bananas, and that this may have a great influence on the production of a high death-rate, yet may there not be a reason for the mother saying that "milk is not a food"? The real meaning may be that the milk produced by the mother is not of a quality sufficient to cause healthy growth in her offspring

The information, so far as it goes, seems to suggest that at least amongst some of the tribes the native population is no better physically and no less susceptible to disease than Britain's C3 population Vegetarian diets, such as that used by the Kikuyu, even when accompanied by abundant sunshine on a half-naked body, is evidently no guarantee of health and no sure prevention against diseases such as tuberculosis and cancer, which are sometimes attributed to lack of sunshine and the use of the refined foodstuffs of civilisation A study of the conditions in one of these reserves, where the infant mortality is so much higher than that of Britain, where women suffer from senile decay at an age when British women are approaching their prime, and where, in addition to malaria yaws, and diseases due to intestinal parasites the worst diseases which affect the people of civilised countries are also prevalent affords no support for the view that the adoption of the dietary habits and the primitive methods of life of the African native would lead to the elimination of disease

These problems of the nutrition of the native have received more than local attention Through the good offices of the Empire Marketing Board it has been possible to obtain the cooperation of experts in nutrition in Britain A Committee, consisting chiefly of members of the Nutrition Committee of the Medical Research Council and medical representatives of the Colonial Office, have outlined a scheme of investigation on problems of nutrition among the native races of Kenya Two research workers have been sent out from the Rowett Institute, and experienced officials of the Kenya Medical Service will cooperate with them in carrying out investigations to determine whether there is any correlation between diet and diseases in the natives

SOCIAL CONDITIONS AND ACUTE RHEUMATISM.

REPORT ON INVESTIGATIONS IN LONDON AND GLASGOW

IF the factors determining the greater incidence of acute rheumatism in the hospital class, as compared with the well-to-do, could be ascertained, steps might be taken to prevent its occurrence and moreover some light might be thrown on the causation of the disease

This was the starting-point of a searching inquiry made simultaneously in London and Glasgow under the auspices of the London Committee for Child Life Investigation, over which Dr G F Still presides This is one of the standing scientific committees appointed by the Medical Research Council; its members include Dr John Brownlee, Dr H C Cameron, Dr J S Fairbairn, Mr Eardley Holland Dr R C Jewesbury, Prof M S Pembrey, and Dr O L V de Wesselow, who acts as secretary

Dr Still, in an introduction to the report[1] of the results of the investigation, sets out the reasons why it seemed worth while to make a thorough survey of the conditions under which rheumatism arises, the parentage, the family incidence, the environment, especially as to housing, clothing, and cleanliness, also the physical characteristics of the children affected, especially as regards the state of the throat It was not practicable to obtain for comparison any sufficient statistics on similar lines from families of the well-to-do, so it was decided as far as possible to check the results obtained by comparison with non-rheumatic families of the hospital class These families were selected only in that each contained a child attending the hospital for a non-rheumatic disease, and are termed "control families"

The Data of the Investigation

The data on which the investigation is based consist of the medical and social histories of 721 families containing at least one child who is, or has been, under treatment for rheumatism Of these, 121 histories were compiled at the Children's Hospital, Great Ormond-street, London, 200 at the Royal Hospital for Sick Children, Glasgow, and 400 at St Thomas's Hospital, London For comparison with these "rheumatic families" the histories of 200 "control families" were investigated, 100 at the Royal Hospital for Sick Children, Glasgow, and 100 at St Thomas's Hospital, London In addition, the rheumatic histories of some 2000 children residing in Poor-law schools were ascertained

It is made clear at the outset that throughout the report the term rheumatism is used to indicate only the disease sometimes known as rheumatic fever or acute rheumatism, with its recognised manifestations Vague aches and pains or tonsillitis were not accepted as evidence of rheumatism, and none of the forms of so-called rheumatoid arthritis were admitted, since there is no reason to suppose that they have any connexion with the disease under investigation At St Thomas's Hospital, under arrangements made by Dr J S Fairbairn and Dr. O L V de Wesselow, the children were examined by Dr. C K J. Hamilton and Dr J Forest Smith Inquiries into the social history were made concurrently by Mrs M Forest Smith The second series at the Hospital for Sick Children, Great Ormond-street, London, was examined by Dr F J Benjamin, working under Dr Still, the social inquiries here being made by Miss Little In Scotland, Dr Margaret F Lowenfeld and Dr H W Sutherland, worked under Prof Leonard Findlay at the Royal Hospital for Sick Children, Glasgow The supplementary inquiry into rheumatism in Poor-law schools was made by Dr Benjamin

The mass of observations made by the three groups of workers were reduced to a connected report by Mrs M Forest Smith, and Dr J Brownlee and Dr Matthew Young have tested the statistical significance of the results The Council express special appreciation of the aid given by Dr de Wesselow

Dr J A Glover helped in obtaining figures and information as to buried rivers and old watercourses, and the medical officers of health for many London boroughs supplied records of the measurements and sanitary conditions of houses.

Scope of the Inquiry

The scope of the inquiry included the incidence of rheumatism in rheumatic and control families, among living and dead children, the hereditary aspect being specially studied The incidence of sore-throat in rheumatic and control families, the condition of the throat in rheumatic and non-rheumatic members of these families, and the results of throat operations sustained by the rheumatic members of rheumatic families were ascertained Evidence of infectivity was also sought, the possibility of infection from sleeping with a case of rheumatism, instances of the occurrence of rheumatism in persons in close contact with rheumatic patients, and the incidence of rheumatism in families of different size being considered

In order to discover the effect of poverty, hospital patients were divided into three social classes, and the incidence of rheumatism investigated in each class Social points studied included, as factors concerning the child, conditions of life, maternal care, degree of subjection to exposure, sleeping accommodation, clothing, cleanliness, and distance from school; as factors concerning the parents, their characteristics, birthplace, general condition, occupations and incomes The types of housing, position of rooms occupied, aspect of rooms and houses, number of rooms per family, number of persons per room, ventilation, lighting, air space per person sanitation, vermin, dust, dampness, locality—all came within the purview of the investigation

The seasonal incidence of rheumatism and even the incidence of rheumatism in relation to pigmentation of hair and eyes was studied, while the incidence of rheumatism in four Poor-law schools visited was compared with its incidence, as found by other observers, among children attending public elementary schools

General Conclusions

It is admitted that the conclusions drawn from this exhaustive survey are mainly negative, but a few definite findings emerge The details must be sought in the report Some of the general conclusions drawn by Dr Still in the final chapter of the report are set out below —

Family Incidence —There was found to be clear evidence of family incidence, rheumatism was common in the parents or brothers and sisters of the rheumatic child This might indicate inheritance of the disease or of some special tendency to the disease, but, on the other hand, it might be due to similarity of environment, or again it might be due to contagion

---

[1] Medical Research Council Special Report Series, No 114 H M Stationery Office Pp 108 2s 6d

Heredity —No sufficient evidence of heredity was forthcoming A history of rheumatism in grandparents can seldom be verified , parental rheumatism can be ascertained with a nearer approach to accuracy Careful inquiry showed that rheumatism had occurred in the father or mother in about 20 per cent of the rheumatic families , but in the control families there was also parental rheumatism, less indeed but still in one set of figures as high as 17 per cent , in another 11 per cent . so that it may be doubted whether the excess of parental rheumatism is sufficient indication of heredity

Infection or Contagion —The relation of rheumatism and its family incidence to environment has occupied the greater part of the investigation The question of infection or contagion is necessarily closely connected with that of environment In view of the heavy incidence of rheumatism upon children of the hospital class as compared with that upon children of the wealthier classes, it might be expected that the incidence of rheumatism amongst the former would be in direct relation to the degree of poverty This, however was found not to be the case ; indeed, if the hospital patients are divided into three classes according to the degree of poverty, the poorest of these three, the very poor and destitute, show a lower incidence of rheumatism than the other two It would seem, therefore, that if poverty is a factor in the incidence of rheumatism it must be on account of some condition or conditions associated therewith which are not equally present in all degrees of poverty

A comparison between the rheumatic and non-rheumatic children in respect of home conditions seemed to show that in the rheumatic families the maternal care was less good, and therewith exposure to cold and wet was more common and clothing less satisfactory The housing inquiry threw but little light on the problem , dampness which has generally been credited with playing a large part in the causation of rheumatism was only slightly more frequent in the houses of the rheumatic families than in those of the others Overcrowding of rooms did not seem to be commoner amongst the rheumatic families than amongst the controls, nor was there any appreciable difference between the two as regards sanitation in London, but in Glasgow the proportion of rheumatic families living in houses with bad sanitation was appreciably larger Neither ventilation nor lighting appeared to be any worse in the homes of the rheumatic families than in those of the controls

These findings are based upon a comparison between the families of rheumatic children and those of non-rheumatic children, all of the hospital class , it may be that an investigation of the conditions under which the rare occurrence of rheumatism takes place in the children of the well-to-do, whose environment is less similar, would throw into more prominence any common factor of causation If rheumatism is due to infection its incidence may be determined by special frequency or closeness of exposure to infection, or by some condition in the particular children concerned rendering them especially susceptible to infection With regard to the former, in the absence of any certain knowledge as to the mode of conveyance of infection, it was decided to investigate the frequency of exposure to some of those sources of infection which are recognised as responsible for other diseases The presence of vermin such as fleas, bugs, body-lice, and head-lice was found to be not more frequent in rheumatic families than in others , sanitation in the London area was no worse in the houses of the rheumatic than in those of the control families

The possibility of direct contagion from person to person is difficult to exclude If it occurred it would go far to explain the greater frequency of rheumatism amongst the children of the poorer class than amongst those of the well-to-do for the former live under conditions of much closer contact In the homes of the hospital children it was found that commonly two children and often three or more slept in one bed

Inquiry showed that in many instances a rheumatic child shared a room or a bed with a sister or brother or that a rheumatic parent slept in the same room with the children It could not be proved that infection had occurred in this way , on the other hand, individual instances were noted in which it seemed at least possible that the disease had spread in this way from one child to another The question is not an easy one to determine, for even if in the chronic stage which many of the children had reached, there was no apparent spread to other children by contact, it is still possible that in the earlier and more acute phase there may be a time at which spread by contagion is possible , moreover, contagion if it occurs may be indirect , it is conceivable that a room or a house may be infected by some occupant, particularly, perhaps, by one who was there in the early acute stage of the disease It was hoped that this point might be investigated, but it was found impracticable to ascertain in any sufficient number of cases the antecedents in the house Clothes also might be a source of infection, and it was noted that there was less individual proprietorship of clothing amongst the children seen at hospitals than is usual amongst the well-to-do The time relationship of the onset of rheumatism in two or more members of the same family was in individual instances suggestive of the possibility of contagion direct or indirect

On the whole while it cannot be said that there is, in the facts collected, any conclusive evidence of contagion, many of them are consistent with this view

An unhealthy throat was noted in a higher proportion of rheumatic children than in non-rheumatic , the difference, however, was not very large It is perhaps significant that amongst the children in the Poor-law institutions in the London area the proportion of healthy throats was much higher than amongst children of the same class living in their own homes in London This suggests that environment plays some part in the production of unhealthy tonsils, and that this is one direction in which environment affects the incidence of rheumatism The effect of tonsil operations was investigated It was found that neither cutting nor enucleation was any guarantee of immunity from rheumatism ; out of 295 rheumatic children who had had their tonsils surgically treated, 129—i e 43 7 per cent —developed their rheumatism for the first time subsequently, and this although in about half the number the treatment had been complete enucleation of the tonsils

Whilst therefore an unhealthy state of the tonsils may favour the onset of rheumatism, it is clearly not an essential factor Statistical evidence seems to confirm the association between unhealthy tonsils and rheumatism, though it does not prove that the rheumatism is a result of the tonsil condition , the converse indeed might be true If, however, the unhealthy state of the tonsils is to be regarded as causal, such a view would be consistent with an infective agent as the essential cause of rheumatism and would not exclude the possibility of contagion Indeed, on the analogy of other infective diseases it makes intelligible the possibility that close contact would favour the transmission of the disease

Notification —Possibly more light might be thrown upon the question of the spread of rheumatism, whether by contagion or otherwise, if it were made a notifiable disease This would at any rate secure information as to its prevalence and distribution, matters of practical importance if institutional treatment upon a wide scale is desirable for children with rheumatism The difficulty of notification would be considerable for the diagnosis of the more characteristic manifestations of rheumatism heart disease, and chorea, and even the acute articular affection is by no means free from possibilities of error and in its less pronounced forms rheumatism may be very difficult to diagnose

In the meantime it appears from this inquiry that although it is difficult to point to this or that fault of environment as responsible for *rheumatism* nevertheless it is by raising the standard of environment, improving the home conditions so that they approximate to the well-ordered conditions found in such institutions as those in which rheumatism was found to be much less common and probably by reducing crowding, so that the possibility of contagion may be diminished that we may hope to reduce the frequency of rheumatism in children

MEDICINE AND THE LAW.

Miner's Nystagmus: Proneness to Recurrence

A MEDICAL referee under the Workmen's Compensation Act occasionally encounters difficulty in certifying an industrial disease which is prone to recurrence; the symptoms are found to be present at one date but not at another, and the question arises of the continuance of the disease This difficulty occurred in a case lately decided by the House of Lords A miner, employed for 35 years in a colliery, was certified in July, 1923, to be suffering from nystagmus, an appeal against the certificate to a medical referee was dismissed He received 35*s* weekly compensation under the certificate for three weeks; afterwards he was given light work above ground A year later he was again certified to be suffering from nystagmus; for a month he received compensation, then went back again to light work In February, 1925, the county court registrar made an order for his examination by the medical referee, who was asked to certify as to his condition and fitness for employment, to specify (if necessary) the kind of employment for which he was fit, and to say whether the incapacity was due to the industrial disease and whether he was fully recovered from the nystagmus The medical referee did not answer all these questions categorically He certified that the man was not suffering from miner's nystagmus, that he was hypermetropic and had incipient cataract, that his condition was such that he was fit for surface work, and that his condition was not due to nystagmus Fortified by these findings the colliery proprietors ceased to pay compensation In July, 1925, however, the miner was again certified to be suffering from nystagmus Appeal from the certificate was dismissed, the referee certifying that the workman's present condition was that he had nystagmus and also lens opacities Four months later the workman applied for arbitration, but the colliery denied liability on the ground that the certificate of February, 1925, was final and conclusive, and that the workman could not go behind it The county court judge had evidence before him that nystagmus was an industrial disease which comes and goes, and that at the moment of the county court hearing the workman was incapacitated by nystagmus The medical referee, it was true, had been asked in February, 1925, to say whether the man had recovered from the disease, and he had answered that the workman was not then so suffering, but he had not reported that the workman had fully recovered The county court judge did not feel himself debarred by the certificate of February, 1925, from finding that the workman was in fact suffering from nystagmus at the moment, and he awarded the man compensation at the rate of 10*s*. a week There is good legal authority for saying that a certificate is conclusive only of matters referred to therein as at its own date, and is not to be taken as amounting to *res judicata* between the parties Following this authority the Court of Appeal upheld the judge's award and said he was justified in inferring from the later certificate that the workman had a special susceptibility to nystagmus which had broken out after the earlier certificate The House of Lords concurred and dismissed the employers' appeal Their lordships said the medical referee's certificate of February, 1925, did not certify that the workman had fully recovered from the original attack though the medical referee had been expressly asked to report upon this point. The certificate meant only that the symptoms of nystagmus were not apparent at that time and that there was at that time no incapacity due to nystagmus As the county court had uncontradicted evidence before it that nystagmus came and went, the county court judge was entitled to hold that the workman was at the date of the hearing suffering from the disease originally contracted in 1923

Hospital Treatment and Poor Relief

If anyone, treated as a private patient in a hospital maintained by the guardians out of the rates, pays for the whole of the treatment out of his own pocket, can he be said to have received poor relief? The significance of the question is that the acceptance of union or parochial relief disqualifies a guardian from holding office. The point came before the Divisional Court and (on appeal) the Court of Appeal in January The proceedings—as often happens in local government litigation—sound a little complicated They took the form of an application by an elector for an order of the Court to direct the Dartford Guardians to show cause why a writ of mandamus should not issue to command them to declare vacant the office of guardian held by a lady who, since her election as guardian, had received—it was suggested—"union or parochial relief" The ground of the application was that the lady had been a private patient in the King Edward Avenue Hospital, Dartford, which was maintained by the guardians out of the rates An operation was performed upon her by her own doctor, who attended her subsequently at the hospital, the anæsthetic was administered by the medical superintendent of the hospital, who was not a whole-time officer, but was paid a separate fee by the guardians for his services The lady paid for her conveyance to the hospital and for the whole cost of her maintenance and treatment there, but the applicant in the Divisional Court said that the facilities she received made her technically a pauper, a view said to be accepted by most boards of guardians and not openly repudiated by the Ministry of Health Private patients, of course, were not admitted to this hospital at Dartford if such admission would interfere with the treatment of other patients by way of poor relief.

Lawyers have expressed doubt whether the treatment of a private patient for payment in a rate-maintained hospital was to be regarded as a privilege or advantage which amounted to the receipt of poor relief Four years ago (in the case of Chard *v* Bush) Mr Justice Sankey held that the receipt of money from the local authority by way of loan amounted legally to poor relief This was because the Acts which were material in that case repeatedly spoke of "relief on loan" and "relief by way of loan" In the recent Dartford case Mr Justice Salter said that, as the guardians had been paid in full, there was no evidence on which the lady could be said to have received "union or parochial relief" within the meaning of the Local Government Act The Court of Appeal upheld this decision The grant of the writ of mandamus is discretionary, and the superior Court saw no reason to interfere with the discretion exercised by the Court below. Modern statutes usually deal carefully with matters of disqualification For instance, the Housing (Rural Workers) Act, passed last year, saves the position of a member of a local authority who receives a grant or loan under the Act, but he must not vote on any resolution or question relating to a house or building in which he is interested.

Certificate of Cause of Death Apparent Insufficiency of Information

The Births and Deaths Registration Act of 1874 lays down that "in case of the death of any person who has been attended during his last illness by a registered medical practitioner, that practitioner shall sign and give to some person required by this Act to give information concerning the death a certificate stating to the best of his knowledge and belief the cause of death" The recently passed Births and Deaths Registration Act of 1926, which comes into operation on July 1st of this year, does not substantially change the position From time to time doubt arises how far a doctor who has attended a patient has sufficiently recent knowledge of the case to be able to certify the cause of death At an inquest at Lewisham the coroner for South-East London has lately had occasion to express this doubt rather sharply. A man aged 67, previously engaged in the trade of organ-building, was treated last September and subsequently for atrophy of the hands. One morning he was found dead in bed. The widow appears to have attempted to communicate by telephone with the specialist who had treated the deceased; it was found that the specialist was absent in France. Communication was established by the aid of the aeroplane post, and by this means a certificate was obtained which purported to state that death was due to progressive muscular atrophy. Major W. H. Whitehouse, the coroner, had before him at the inquest the evidence of Dr. T. E. White, of Catford-hill, to the effect that death was due to hæmorrhage from gastric ulcer. The coroner asked the widow how a doctor living in France could know that her husband had died from progressive muscular atrophy. She agreed that the specialist had not seen her husband during the last week nor since the death. Major Whitehouse recorded a verdict of death from natural causes and remarked, with regard to the certificate which had been produced at the inquest, that it was the most irresponsible thing he had ever met with.

The court was not, of course, aware of anything which the absent practitioner might have had to say in justification of an opinion expressed no doubt in perfect good faith and perhaps given, in the hurry of the circumstances and at the urgent instance of the relatives, without the usual care. The incident shows the danger of certifying the cause of death without adequate and recent information.

BERLIN.

(From our own Correspondent.)

Legislation against Venereal Disease.

After long Parliamentary debate the new Bill for the control of venereal disease has become law. Persons suffering from these infections will now be obliged to have themselves attended by a medical man, guardians being made responsible for the treatment of wards and minors. For paupers and people who are not obliged to belong to a sick-club and are unable to pay for medical attendance, the local health authority will have to make arrangements. Anyone suspected of suffering from venereal disease may be directed by this authority to submit a medical certificate that he is healthy, and if he does not comply with this demand he may be examined by a medical officer. The law, however, expressly forbids the authorities to consider anonymous communications. Sexual intercourse by a person who knows that he or she suffers from a venereal disease may be punished by imprisonment up to three years, and similar penalties may be inflicted on anyone who is infected and who marries without mentioning the fact to the other party to the marriage. In these cases no official action is taken except on the special request—which may afterwards be withdrawn—of the injured party. Medical attendance on venereal disease is allowed only to medical men or women, and medical advice without examination is forbidden and may be punished by imprisonment and fines. An unqualified person attending venereal patients is liable to suffer the same consequences, whilst patients who interrupt their course of treatment before being declared cured by their medical attendants are liable to have their names reported to the local health authority. Medical and other Government or municipal officers are bound to keep strictly secret the fact that a person is suffering from a venereal disease, and those who disregard this obligation may be given a year's imprisonment as well as being fined. Advertisement of remedies for the cure of venereal disease is not to be allowed except in medical and pharmaceutical journals. Public lectures on the dangers of venereal diseases are permitted provided that they are held only for purposes of instruction. The Act further makes the following persons liable to 12 months' imprisonment and a fine: (1) A wet-nurse who before being employed conceals the fact that she is suffering from a venereal disease. (2) People who allow a syphilitic infant to be nursed by anyone other than its mother or a syphilitic nurse. (3) Those who allow an infant suffering from venereal disease other than syphilis to be nursed by a wet-nurse without informing her of the fact and without providing for prophylactic measures. (4) Those who give a child suffering from a venereal disease to foster-parents without informing them that it is infected in this way. A wet-nurse before being employed must in future produce a certificate of health. The Act finally prohibits brothels and contains provisions for the housing of prostitutes.

This new legislation certainly restrains the personal liberty of the individual for the sake of the community to an extent hitherto unknown in this and many other countries. Its principal feature is that henceforth men and women will be subjected to the same rule so far as the spread of venereal diseases is concerned; until now a man could not be punished for his misdeeds, whereas a woman could eventually be registered as a prostitute and suffer all the consequences of that registration. It is satisfactory that quacks are expressly excluded in the above Act from any form of attendance on venereal patients; this provision, indeed, caused a good deal more debate in Parliament than many of the other provisions of this very incisive Act.

Can a Qualified Medical Man Practise as a Quack?

The existing laws governing medical practice sometimes lead to rather ridiculous results. According to the regulations a qualified medical man, before beginning practice in any district, has to call personally on the district medical officer of health and show his diplomas; he is thereupon registered in the district, and his registration notified to the central authority. People without qualifications, if attending patients for money, have also to present themselves to the medical officer of health for purposes of control. The financial success of many unqualified persons has caused a certain number of medical men to settle as quacks, and recently one of them presented himself to the district medical officer without mentioning that he had a regular qualification. When this was discovered he was prosecuted for having broken the regulations of medical practice. The defendant pleaded that he had intended to make no use of his qualification and would have abstained from treating diseases and from prescribing any drugs which must only be dealt with by the medical profession. The Supreme Court of Prussia held that a medical man before beginning practice must certainly show his diploma to the competent authority. Even if he intends to practise not according to the methods of scientific medicine but of quackery, he must, nevertheless, follow the laws and regulations concerning the medical profession. Should he desire to make no use of his diploma he may only do so by an express statement of his intention. Whether a medical man can altogether renounce a qualification duly obtained the Prussian Court was unable to decide, for this matter falls under the jurisdiction of the Imperial Court.

Statistics of Diabetes.

Dr. Ullmann lately read before the Society for Internal Medicine a paper on the frequency of diabetes. Notification of diabetes not being compulsory, nothing more than the mortality which it causes can be ascertained, this being estimated from the statements on death certificates. During the late war the mortality from diabetes was decreasing, not only amongst the belligerents but also in neutral countries such as Switzerland; in Berlin it fell from 23 per cent. in 1913 to 11 per cent. in 1920. Undoubtedly restriction of diet contributed to this decrease, especially in Germany, which suffered most of all from shortage of food. Even in the United

States of America, where there was but little control of food, there was a small decrease In rural districts, where food was not, of course, so scarce as in the towns, the lowered death-rate was less marked The statistical records of Europe and the United States have made it obvious that since the middle of 1921 diabetes has again been on the increase It is not nervous strain which causes the disease, but lavish nourishment with too little bodily exercise Sports is a prophylactic against it. It is remarkable, however, that women now contract diabetes more often than formerly In the discussion Prof Beugsch stated that in one-third of the cases a hereditary factor could be traced He thought that the prevalence of the disease was a symptom of degeneration in the population. The severe forms of diabetes in young people have not increased, it is amongst adults that the condition is growing more common

A New Medical Journal.

To the great number of German medical periodicals a new one has recently been added under the name of the *Medizinische Welt* The editors are Dr Dietrich, late director of the Prussian Medical Department, and Dr Beyer and Dr Ostermann, at present officers of the department In their introductory article they explain that the new journal is especially intended for the average practitioner who is not in a position to read the detailed articles in the great scientific journals They will therefore lay stress on shorter articles without long lists and description of experiments, and will deal with medical research, practice, politics, instruction, technique, and medical news in general Three numbers of the new journal have so far been issued, it is well printed and contains numerous illustrations, including photographs of the authors of the principal articles

(FROM OUR OWN CORRESPONDENT)

Effect of Euphyllin on Respiratory Paralysis

Dr Vogl has reported to the Gesellschaft der Ärzte on his investigations into the effect of euphyllin (theophyllin and ethylene diamine) on cases with diminished excitability of the respiratory centre and cerebral cortex Whilst injecting euphyllin intravenously to increase diuresis, he found that the volume and rate of breathing were markedly increased Experiments on himself showed that this increase could not be voluntarily controlled, and he found that the drug gave very satisfactory results in patients who had Cheyne-Stokes breathing A few seconds after intravenous injection the rhythm became regular and this effect sometimes lasted for as long as 60 hours In cardiac dyspnœa the feeling of oppression was rapidly relieved, and in conditions of coma—e g, narcotic intoxications—the patients could be recalled to life almost instantaneously It seems, therefore, that we may have in euphyllin a useful analeptic for use in cortical paralysis As the substance has a very powerful effect on the circulation, it is not quite certain whether its rapid action is not due to a combination of cerebral and circulatory stimulation Experiments by Guggenheimer, Elias, and others seem to point to a double plane of attack But in cases of uræmia, apoplexy, and cerebral tumour, in which circulation was not disturbed, the effect was just as prompt, and Vogl therefore thinks that the cortex is the true seat of the drug's action However this may be, it now appears that we have a remedy which is able to abolish Cheyne-Stokes's respiration as quickly as morphia abolishes cardiac asthma

The Campaign against Vivisection

The Vienna Society for the Prevention of Cruelty to Animals has again been giving a lot of attention to the old problem of vivisection The public has been pressed to take action to stop all experiments on animals in this country, but as these are performed only in university laboratories and institutes, and only by competent investigators, the reason for the Society's sudden activity was not at first evident The precautions required both by the Government and by the University do not allow any true vivisection—that is to say, bloody or mutilating experiments on living creatures—without sufficient anæsthesia, and an anæsthetic is required by law, except where lower animals such as frogs are used On the other hand, the law does not prevent research laboratories from using mice, rabbits, cats, and dogs for testing vaccines and serums, this not being regarded as vivisection, and it has become evident that the campaign, conducted by the Society for the Prevention of Cruelty to Animals, was only a sham fight, being mainly aimed against vaccination, which is almost compulsory in this country. The Society's circuitous plan was to make the preparation of calf's lymph unlawful under the guise of forbidding vivisection, but, of course, the medical authorities lost no time in telling the public what all this implied, and the attack upon the liberty of teaching and research has definitely failed

Nutrition and Lithiasis

At the last meeting of the Vienna Medical Society Prof Tadasu Saiki, of the University of Tokio, read an interesting paper on the correlation between malnutrition and disease, and demonstrated a series of calculi taken from the kidneys, bladder, and gall-bladder of animals fed on a diet free from vitamin A. Whereas in human beings deprivation of this vitamin leads chiefly to osseous changes, the effect on animals is often to produce lithiasis The extraordinary thing is that, according to Dr Saiki, these can be made to disappear if the animals are again given an adequate supply of the missing vitamin, the stones are apparently redissolved In another series of experiments at the Japanese Institute of Nutrition (of which Dr Saiki is the director) the animals were fed on food not free from vitamin A, but poor in it. It was found that after a long period—up to 280 days—these animals developed an induration of the tissues, whilst in several instances formation of distinct cancer tissue was noted These experiments seem to support the old theory that organs undergo malignant changes as a result of insufficient nourishment In the discussion which followed, Prof Pirquet, who translated Dr Saiki's address from English into German, pointed out that this Japanese research ought to be followed up in the areas known as "stone districts" It would be very interesting if it were shown that the food of the people in these districts was deficient in the way suggested

Spread of Influenza in Austria

For some time almost the whole of Central and Western Europe has been the hunting-ground of influenza, and the epidemic has at last reached Austria There are now over 30,000 cases here, but the mortality is happily very low The present *genius morbi* is characterised by sudden high pyrexia (over 40° C), great prostration, and rapid recovery, whilst an intense hyperæmia of the fauces and inflammation of the upper respiratory passages are always present A frequent complication is otitis of a mild type, and also suppurative inflammation of the accessory nasal sinuses Apart from influenza, we are at present suffering from an outbreak of measles, which is of rather severe type, and commonly leads to aural and pulmonary complications

The Value of X Rays in Diseases of the Ear

At a recent meeting of the Vienna Society of Rontgenology Dr Otto Mayer dealt with radiographic examinations of the temporal bone This has two objects—namely, to define the anatomical structure of the bone and to ascertain its pathological condition The anatomical structure can be made out very definitely, and before operating the surgeon can get exact information about the position of the sinus sigmoideus, the aeration of the mastoid process, and the presence of solitary air-cells To find out how much destruction has been wrought by an acute or chronic otitis is only possible if the radiographic appearances are correlated with the clinical findings, which is true, of course, of other investigations with X rays At the Vienna Otological Clinic it has for several years been the practice to take a radiogram in every case of inflammation. In severe cases, when the question of operation or conservative treatment is raised, the X ray findings are decisive In the difficult cases of otitis with few or no symptoms such an examination will often convince patient and surgeon that active interference is required, whilst in other cases it may show that disturbing symptoms arise from some other cause Less importance is attached to radiography in non-surgical diseases of the ear, for the appearances seen in otosclerosis or catarrhal deafness are not by no means characteristic There is no doubt, however, that in otology much information concerning pathological processes can be gained by cooperation of the radiologist with the physician and the surgeon.

IRELAND

(FROM OUR OWN CORRESPONDENT)

The Duties of the Coroner

THE Coroners (Amendment) Act, which has recently received the assent of the Governor-General of the Irish Free State, has made several important modifications in the law The duty is laid upon the coroner to hold an inquest on a body lying in his district when there is reasonable cause to believe that the person has died a violent or unnatural death, or has died a sudden death of which the cause is unknown, or that he has died in prison or in such place or in such circumstances as to require an inquest under any Act other than the Coroners (Ireland) Act, 1846 Secondly, in other cases than those just recited, when the coroner is informed of the death within his district of a person who was not attended in his last illness by a qualified practitioner, or in regard to whom a medical certificate of the cause of death is not procurable, he may inquire into the circumstances of the death of such person, and if he is unable to ascertain the case of death he may, if he thinks fit, hold an inquest In case of these inquiries being made, he is empowered to order fees to be paid for any investigation, including a post-mortem examination, undertaken at his request by a *medical practitioner* The maximum fees payable to medical practitioners, both for post-mortem examinations and for giving evidence, are: (1) for giving evidence without making a post-mortem examination, two guineas, (2) for making a post-mortem examination and reporting the result thereof, without giving evidence, three guineas, (3) for making a post-mortem examination and giving evidence, four guineas Provision is also made by which the Minister for Justice may, on request from the coroner, make arrangements to supply him with expert assistance

With certain specified exceptions, which cover most cases from which a criminal charge might arise, the coroner may hold an inquest without a jury The number of the jury in other cases is to be not less than six, *nor* more than 12 Moreover, in the event of disagreement, if the minority be not more than two, the coroner may accept the verdict of the majority In other cases of disagreement he must summon a fresh jury and begin the inquest again The duty of visiting the body is taken off the jury and put on the *coroner* In cases where a coroner has reason to believe that a death has occurred in or near his district in such circumstances that an inquest ought to be held, while owing to the destruction of the body by fire or otherwise, or to the fact that the body is lying in a place whence it cannot be recovered, the ordinary procedure cannot be followed, he may report the circumstances to the Minister for Justice, who may, if he thinks fit, direct an inquest to be held

An important change is made to avoid the inconvenience of a coroner's inquest and a magisterial investigation being held simultaneously in regard to the same occurrence. In the event of the coroner being informed that any person has been charged with the murder, manslaughter, or infanticide of the deceased, he shall adjourn all further proceedings until the criminal proceedings have concluded, when he may, if he thinks necessary, resume the inquest It is made the duty of every council which has power to appoint a coroner, within 12 months from the passing of the Act, to consider, and if it seems desirable, alter the salary or salaries of the coroner or coroners appointed by such council, always provided that the salary of an existing coroner shall not be diminished

It will be seen that the various changes made by the Act all tend to render the functions of the coroner more useful to the community.

County Medical Officers of Health

A deputation from the General Council of County Councils waited on the Minister for Local Government and Public Health last week to discuss the appointment of county medical officers of health Senator P Kenny, who introduced the deputation, stated that the General Council of County Councils had, in 1923, approved of the appointment of these officers In doing so they followed the recommendations of the Irish Public Health Council, which suggested that half the cost should be borne by the State and half by the county councils The Act of 1925, however, put the entire cost on the county councils There was a heavy financial strain on the councils at present, and he asked that the question of dividing the cost between the State and the local authorities should be reconsidered In reply, the Minister (Mr James Burke) recognised the fact that the present opposition of the councils was due to a temporary difficulty He had no desire to press hardly on them, but as the Act had been passed, it was his duty to enforce it The present medical officers were not able to cope with the situation, particularly as regards the preventive side of the medical service When fevers broke out the local officers had not got adequate machinery to deal with them Then there was the commercial aspect which would become more important as time went on At present Irish produce enjoyed a very favourable position in the English market but there was a tendency to criticise the conditions under which foodstuffs were produced If the standard of inspection in the Free State was not raised to the level of English inspection it was quite possible that their produce would be put under a ban, particularly pork and butter The Minister stated that any additional expense above the salary of the medical officer would be shared equally by the State

---

DONATIONS AND BEQUESTS—Mr. John Daniel Rowlands, of Cardiff, left £1000 to Cardiff Royal Infirmary—Mrs Mary Jane Gibbons Newcastle-on-Tyne, left £300 to the Home for Destitute Crippled Children, Salters-road, Gosforth, £500 each to the Royal Victoria Infirmary, Newcastle-on-Tyne, and the Wesleyan Missionary Society, £300 each to Muller s Orphanage, Bristol, the Northern Counties Orphan Institution for Boys and Girls, the Fleming Memorial Hospital, and £210 to St Dunstan's Home The residue of the property for distribution among such charities as the executors shall determine—Miss Mary Sarah Phillips, of West Mall Clifton Bristol, besides many other bequests, gave £1200 to the Bristol Royal Hospital for Sick Children and Women £1500 to the National Lifeboat Institution for a boat to be named the "Augustus Phillips"; £100 each to the Bristol Royal Infirmary and the Bristol General Hospital, and £300 to Dr Watson Williams and his wife "in deep appreciation of the great and unfailing goodness during my long and serious illness"

THE TREATMENT OF HERNIA

To the Editor of THE LANCET.

SIR,—Prof E M Cowell, in his Hunterian lecture on Hernioplasty, has raised some interesting points, for the question of the recurrence of hernias after operation seems to be somewhat in the air at the present moment There is, however, one point in Prof Cowell's method of treatment which he does not make clear On what principles does he choose his patients for performing his "flap operation"? The fact that he has done the operation 201 times in the course of two years seems to imply that he employs his method as a routine in all cases But if so, is this really necessary? I think most surgeons are agreed that for the great majority of patients, that is to say for those with an ordinary oblique hernia, the removal of the sac is the prime necessity and that if this is done properly the details of the rest of the operation are comparatively unimportant It would be unnecessary, therefore, to perform a hernioplasty as a routine In my own experience recurrences of hernia have been usually due to a failure either to remove the sac or to realise that the hernia was direct

Prof Cowell also implies that the operation of fascia suture as described by Gallie and Mesurier is unpractical and capable of improvement I have used their original technique[1] in the treatment of a number of extreme cases of hernia and have found that with a little practice the operation is eminently practical and satisfying It is for use in the really difficult cases that their technique was devised, and I am sure that the substitution of short strips for long ones is not likely to be an improvement.

I am, Sir, yours faithfully,

London, March 7th, 1927 GEOFFREY KEYNES

To the Editor of THE LANCET.

SIR,—In the very admirable Hunterian lecture on Recent Advances in the Surgery of Hernia delivered by Prof E. M Cowell and published in THE LANCET of March 5th, one sentence should, in my opinion, not be allowed to pass without comment This sentence reads "fascia is a slipping tissue and is not easy to manipulate as described by Gallie and Le Mesurier"

I have used the method described by Gallie and Le Mesurier, since its publication in the *British Journal of Surgery*, for large ventral, incisional, and other types of recurrent hernia It has also been used constantly in appropriate cases by my colleagues The fascial sutures are quite easy to manipulate

For medium-sized or small hernias the "improvements" on the method may be useful, but for very large and difficult hernias, it will be found that success will be uniform and complete in proportion to the exactitude with which the details given by Gallie and Le Mesurier are being followed

I am, Sir, yours faithfully,

London, W, March 8th, 1927 T. P DUNHILL

FEMORAL THROMBOSIS FOLLOWING INFLUENZA

To the Editor of THE LANCET

SIR,—The following case has recently been under our care

A man, aged 37, was seen on Jan 25th, 1927, when he complained of chilliness, headache, pain in the loins and between the shoulder blades, and slight pain in the left chest He had anorexia, his tongue was furred, his temperature was 102° F. and pulse 106 The bowels had been open and there were no physical signs A diagnosis of influenza was made

On Feb 3rd, after his temperature had been normal for two days, he was allowed to rise On the 7th he complained of severe pain in the left leg This pain had commenced early the previous morning in the upper part of the calf and had gradually become worse On examination the left leg was found to be considerably swollen and tense from Poupart's ligament to the foot, and showed a purplish red discoloration There was no difference in temperature between the two legs, and there was pulsation of the posterior tibial artery on both sides The leg was tender over the upper part of the calf, and to a lesser extent, over Scarpa's triangle On the 8th the veins over the whole of the left side of the anterior abdominal wall were more prominent than those on the right side, and on the following day the left side of the abdomen was tender, slightly rigid and discoloured, suggesting a thrombosis of the lower part of the external iliac vein

At 8 30 P M. on the 10th, after the patient had had an enema in the morning with a good result, he stated that he had vomited everything since midday and was feeling very uncomfortable On examination, the abdomen was uniformly distended and tympanitic There was no rigidity or pain on pressure, and his tongue was furred and breath offensive, pulse 84, temperature 99° A turpentine enema was given with no relief The next day he was relieved of his vomiting by fluid diet and tincture of iodine, and was given eserine gr 1/50 every six hours which did not relieve his distension until three days later, when a turpentine enema was administered with a good result

The condition of his leg is showing a steady improvement Possibly a reader of THE LANCET could suggest the cause of the tympanites?

We are, Sir, yours faithfully,

T. R THOMSON

THE BLOOD-GROUPS OF "IDENTICAL TWINS"

To the Editor of THE LANCET

SIR,—Mr. Douglas A Mitchell in his letter which appears in THE LANCET for March 5th (p 513) suggests the possibility of antagonistic "blood-grouping" of the fœtus being a cause of eclampsia He will find some discussion of this question in an article by L Hirszfeld entitled "Konstitutions serologie" which appeared in *Die Naturwissenschaften*, Berlin, 1926, xiv., 17-25

I am, Sir, yours faithfully,

CYRIL C BARNARD,

Librarian, London School of Hygiene and Tropical Medicine

Endsleigh gardens, Euston road, W C, March 4th, 1927

BLACKWATER FEVER IN ENGLAND

To the Editor of THE LANCET

SIR,—Dr P Manson-Bahr's article on Blackwater-Fever in England (THE LANCET, Feb 5th p 273) is of of very great interest but does not account for quite all the conditions met when blackwater fever is found in its own native habitat, of course much of the theory is impossible to controvert but there are almost epidemic forms of blackwater that do not harmonise with the subtertian *causation* I recall a case of a subject who left a certain station near Duala because two of his fellow assistants had died of blackwater fever ten days after coming on board the mail boat, he went down with a sudden and violent attack of the fever With regard to the blood picture, I have never seen the blood plasma in any case of *malaria* present the same appearance as it does in blackwater fever In malarias the corpuscles are broken up and the blood is full of detritus, but in blackwater fever the corpuscles are not broken up, simply drained of hæmoglobin and coloured streaks of hæmatin are free in the plasma There is not even a suggestion of the hæmatin in the malarial blood, so that it does not appear that the hæmoglobinuria is due to an overdose of hæmatin in the blood In blackwater fever the hæmolysis appears to take place suddenly on the onset of the pyrexia. The number of malarial cases which are treated with quinine by mouth and by injection are enormous The cases of blackwater fever are few, and when a patient has been treated with quinine after an attack of blackwater fever, and the malaria-infected corpuscles are seen breaking up, no recrudescence of the blackwater fever is found to occur The blood picture in blackwater fever is typical and quite unlike any ordinary malaria blood and when the blackwater fever disappears an ordinary malaria infected blood is still to be seen Dr Manson-Bahr's theory is most ingenious, and may account for some cases but it is not quite sufficiently in accordance with observed facts to be wholly conclusive Many of the symptoms and characteristics of blackwater fever are very allied to yellow fever and tempt one to imagine a connexion, but the study of Dr Manson-Bahr's cases occurring in England eliminate that possibility

---

[1] Brit Med Jour, Jan 29th, 1927

Following is an account of blood film described with the film under observation at the time of writing.—

The red corpuscles are small and colourless A few corpuscles are seen containing malarial parasites "en vacuole" The blood plasma shows streaks of bright-red colouring matter, looking like transuded contents of red corpuscles as if the hæmoglobin of the corpuscles had *transferred itself to the plasma* The plasma contains a large quantity of high refracting granular matter in clumps and in fine granules There is present, also, an enormous number of polynuclear cells, rather larger than red corpuscles Nuclei deeply stained, nuclei slightly granular, and arranged either in fours or in pairs in each cell, when in fours they are equal in size and regularly placed when in pairs, forming a double horseshoe, equal and opposite, some few cells with large, single and irregular shaped nuclei

The whole question is most important because it raises the point of whether quinine should or should not be administered for severe malaria Good results can be obtained from phenacetin in malaria and possibly with less danger Again, we have heard much argument in regard to the prophylactic value of quinine Personally, when in W Africa I have always taken quinine religiously but notwithstanding have had two severe attacks We know all statistics appear to prove the prophylactic value of quinine but it would be interesting to learn the unbiased views of modern West African medical officers upon this *point* A discussion upon the subject in your columns might be very instructive

During five years work on the coast of *Africa* I had always a microscope at hand with me and examined every blood-infected case that I had to deal with I never saw any other medical man using a microscope in daily practice except in the hospitals of Free Town Accra, Calabar and Lagos The medical officer in Africa ordinarily has not the time at his disposal for much microscope work

I am Sir, yours faithfully,

Southwick, Sussex, March 3rd 1927 E. F GREENE

OPHTHALMIC BENEFIT

To the Editor of THE LANCET

SIR—I have read the letters in your late issues with interest and it seems to me that the question before us is of great importance as the Ministry of Health and the approved societies are seeking to come to a satisfactory arrangement at the present moment and we all want to see the problem clearly and dispassionately settled

First of all "Every man to his own trade" as Mr Lumsden points out An *optician* is a maker of glasses and his business is commercial An *oculist* is versed in the knowledge of the defects and diseases of the eyes and being a fully qualified medical *man* understands the relation of the part to the whole for the eye is only a part of the body and suffers with it both temporarily and permanently The workman needs and demands the same—viz, "the best"—as the rich man and the educated man, and greatly objects to be put off with the "second best"; by his insurance he can afford the best, especially since a large number of first-rate oculists have modified their fees to £1 1*s* for his special benefit He also demands an impartial and truthful opinion, and there should be no room for doubt Opticians should not be allowed to test the eyes and supply the glasses as well, they should be removed from the faintest suspicion of self-interest Likewise, no medical man should be allowed to send a patient to a member of his own firm, excepting in areas where no oculist exists

The opticians are aiming at becoming a profession with diplomas and Government registration, and they instance the case of the dentist But there is no parallel; the dentists have no body of men above them to compete with, they *are* specialists and their education is complete, prolonged, and expensive, and many are fully qualified in medicine and surgery as well as in their specialty

Are the opticians willing to become medical men? If so, why not? Several have become so (of course, they become oculists) Are they willing to give up their advertising and shops and become a profession? Would it pay them? I am convinced that professions and commerce can never combine as the standards are different Why do opticians desire to be third-rate oculists? I imagine to be able to charge fees: but surely they do extremely well financially in selling their goods, and surely the burden, the danger, the responsibility of treating eyes will prove the small fee they charge to be inadequate

The best approved societies seem well pleased with the present arrangements, which give complete satisfaction The only question is, can they afford it? I think there is no doubt they can, but if not surely some insurance scheme can be devised which would easily finance the present moderate charge Certain societies refuse the doctor's certificate and send their clients to the optician first and if the optician says the case is beyond him he (the optician) refers the case to an oculist, and far more often to the hospital, and so a rich society can palm off its clients on *charity (subscribed to in many cases by poor* people); many are the cases that I have had sent to me at the hospitals where I work Of course, the societies do not do this directly; it is done by the optician, but the result is to save a small fee and enable a rich society to become richer by using *charity*. This should be stopped

In reference to Mr Caddy's remarks on refraction, and to presbyopia generally, it is said that opticians do the work very well, also that mere presbyopia does not need skilled knowledge I do not say that the best opticians cannot do refraction well—I think the best can; nevertheless, a "perfect opinion" can only be obtained from the "perfectly educated" Glaucoma can exist with good vision, at least for a *time* It is stated that 95 per cent of an oculist's income is derived from refraction cases, then it is obvious that if you subtract the 95 per cent no oculist could live and ophthalmologists would become extinct Why should the inferiorly educated and commercial body of men be rewarded disproportionately? Presbyopia may be the simplest work we do but when a small correction is added to the presbyopic glass for a slight defect the improvement is great Also much judgment is needed as to the amount of the correction, no rule of thumb can apply, as the ciliary muscle varies in strength and health *in different* cases and the physician-oculist is a better judge than the optician

No one can call our profession commercial when he knows that at the hospitals we treat tens of thousands of patients (many of whom can afford to pay fees) *for nothing* or little, year in and year out.

I wish to remain incognito but enclose my name and address—I am Sir yours faithfully,

March 8th, 1927 F R C S OCULIST

Obituary.

FRANCIS SHILLINGTON SCALES, M D Camb

Many friends and many pupils will have seen with regret the announcement last week of the death at his residence in Cambridge of Dr Shillington Scales, who had been in bad health for a considerable period

Dr Scales was the son of Mr George J Scales, and was born in London and educated privately until he went to Jesus College, Cambridge At Cambridge he took honours in the Natural Science Tripos and later was Raymond Horton-Smith prizeman He completed his medical education at Middlesex Hospital and became attracted by microscopy, which he took up as a special study In 1905 he published a book on "Elementary Microscopy," which was followed in a few years by another treatise entitled "Practical Microscopy" Having proceeded to the M D degree in 1912, he became lecturer in microscopy at the Westminster Hospital Medical School, continuing, also, a close connexion with the Royal Microscopical Society, where he was a Vice-President after holding the post of curator and hon secretary He made frequent contributions on his subject and also upon radiology to scientific literature, and some seven years ago became University lecturer at Cambridge in Medical Radiology and Electrology In connexion with this post he was appointed hon physician in charge of the X ray and electrical department at Addenbrooke's, while he acted as examiner and cretary to the Board of Examiners for the special loma given by the University in those subjects a teacher he was a great success "He had ained himself" writes a recent pupil, "to a very xact use of language and he expected the same accuracy from his students He had developed a vivid word imagery to describe the various appearances or morbid conditions as seen in X ray photographs Here his characteristic expressions of surprise when something unexpected presented itself will remain in the memories of those he taught, as well as the aptness of his Irish stories"

It is a serious loss to the medical profession and to the special studies of Cambridge University that Scales's valuable work in respect of the Diploma of Electrology and Radiology, both in the lecture rooms and in Addenbrooke's Hospital, should be so sadly closed

LOUIS HEMINGTON PEGLER, M.D, C M Edin, M R C S Eng

After living for some years in retirement Mr L H Pegler died at his home at Exeter on Feb 26th The son of Daniel Pegler, he was born at Colchester in 1852 and was educated at the Colchester Royal Grammar School and at University College, London For his medical training he went on to the University of Edinburgh and graduated in 1878, later taking the diploma of M R C S Eng At the age of 28 Mr Pegler entered upon ten years' service with the Clay Cross Company which had a hospital as part of its equipment Soon after retiring from this appointment he began to specialise in aural surgery and for two years acted as registrar and pathologist to the Central London Throat, Nose and Ear Hospital in Gray's Inn-road The work there was in turn given up when in 1896 he became surgeon to the Metropolitan Ear, Nose, and Throat Hospital, on whose active list he remained until 1921 when, as senior surgeon, he retired to the consulting staff He was attached at one time and another to many smaller institutions, and from 1915–18 was in charge of the aural department of the Mile End Military Hospital The anatomical aspects of his work particularly attracted him and he published a map scheme of the trigeminal nerve, besides a number of articles in medical journals At the International Medical Congress held in London in 1913, Mr Pegler was curator of the laryngological museum and a member of the Congress Council He was also elected vice-president of the Section of Laryngology of the Royal Society of Medicine Outside this work in his own line he was interested in biology and especially in botany, besides having a taste for archæology and music

He married Maud Edith, daughter of Mr F W. Palmer, of Bedford

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

Optical Practitioners' Registration Bill.

The text of the Optical Practitioners' (Registration) Bill presented in the House of Commons by Mr. West Russell has now been issued

Clause 3 of the measure provides that any person over 21 shall be entitled to be registered and receive a certificate as a registered optical practitioner under the Act who (*a*) satisfies the Central Optical Board of Great Britain that he holds a recognised certificate, or other evidence of qualification, prescribed by regulations of the Board as sufficient, and that he is of good character, or (*b*) satisfies the Board that he has practised optometry in Great Britain during the five years next before the commencement of this Act and passes to the satisfaction of the Board's examiners a practical examination in optometry deemed by the Board sufficiently comprehensive to safeguard the public, together with evidence of good character, provided that the applicant applies for registration within six months after the commencement of the Act, or (*c*) having completed the prescribed training, has received from the Board's examiners a certificate of competency in the practice of optometry, and produces the same to the Board, and satisfies them that he is of good character The possession of such certificate will entitle the holder to practise optometry and give certificates relating to visual acuity or visual defects which are to be recognised by any local or central authority, or Government Department, in any part of Great Britain

Clause 4 provides for reciprocal arrangements between the Central Optical Board of Great Britain and any board of optical registration, or other competent authority, in any foreign state, or any of His Majesty's Dominions or Colonies, for the recognition of persons entitled to practise under the Act

Under Clause 9 it is provided that any optical practitioner who applies to be registered under the Act shall pay an initial fee not exceeding £5 for registration, and thereafter an annual fee not exceeding £3 for renewal of certificate The Board may charge for any certificate or other document issued, or in respect of any services performed by them, such fees as they may prescribe No person who, having held a certificate under this Act, has ceased for a period of at least two years to hold such certificate will be entitled thereto unless he furnishes to the Board a satisfactory reason for having omitted or ceased to obtain such certificate, together with any proof of good character in the meantime The Board (under Clause 10) can cause to be erased from the register (1) the names of dead persons (2) any entry proved to have been fraudulently or incorrectly made, and (3) any member who is in default in payment of any prescribed fees

The Board, subject to the provisions of the Act, is empowered by Clause 11 to make regulations regarding the removal of persons from the register, the prescribing of fees, the holding of examinations, the prescribing of training in optometry, the issue and cancellation of certificates, the practice of advertising by registered optical practitioners (provided that such regulations shall not prevent the publication of educational matter concerning vision) and so forth Such regulations are to be laid before Parliament for a specified period, and if an Address is presented within 21 days praying that they be annulled, His Majesty in Council may annul them accordingly, but without prejudice to the validity of anything previously done thereunder No person is to be suspended or removed from the Register without being given an opportunity of being heard by the Board, either personally, or with the assistance of counsel Within three months of suspension or removal an aggrieved person may appeal to the High Court whose order shall be final and conclusive, and not subject to appeal to any other court

Persons found guilty of offences under the Act are to be liable on summary conviction to a fine, not exceeding £50, with or without imprisonment, for a period not exceeding three months

In a schedule to the Bill it is provided that the Central Optical Board of Great Britain shall consist of 12 members On its first constitution the Board will be summoned by the Minister of Health and consist of one person appointed by the

General Medical Council, one by the Minister of Health, one by the Scottish Board of Health, one by the Board of Education, and eight others, all of whom shall be optical practitioners, appointed by the Minister of Health after consultation with such associations or organised bodies of optical practitioners as represent to the Minister that they desire to be consulted Such Board will hold that office for two years from the commencement of the Act The second and all subsequent Boards will be constituted in a similar manner to the first, except that the eight optical practitioners will be elected by members of the register from among persons whose names appear on the Register

The Bill is intended to apply to Scotland, but not to Northern Ireland

HOUSE OF COMMONS

WEDNESDAY, MARCH 2ND

Scottish Approved Societies and Dental Treatment

Mr **SCRYMGEOUR** asked the Secretary of State for Scotland whether he was aware that many of the approved societies had been unable to meet their liability for dental treatment under the National Health Insurance Act owing to increased charges, whether such charges were negotiated with the dentists by the Scottish Board of Health without any consultation with any of the other interested parties, and whether, in view of the protests being made, he would reconsider the method of negotiation and suspend the present scale of charges —Sir **JOHN GILMOUR** replied Dental treatment is not a statutory benefit, and approved societies are under no obligation to provide it, but they may do so if they have surplus funds available for the purpose It is not the case that the charges referred to were negotiated by the Scottish Board of Health The scale was agreed by a Joint Dental Committee consisting of representatives of dentists and approved societies' interests I have accordingly no power to take any action such as is suggested in the last part of the question

Small-pox and Vaccination

Mr **GROVES** asked the Minister of Health what were the ages of the nine persons on whose death certificates the word vaccination, or vaccinia, appeared as the cause or one of the causes of death in 1925 and in 1926, and what were the ages of the cases in 1925 and 1926 in which such certification as the cause of death was subsequently withdrawn —Mr **CHAMBERLAIN** replied The ages of the persons referred to in the first part of the question were, respectively, 5½ months, 8½ months 3 months, 5 months, 5 months, 9 weeks, 17 days, 1 month, 6 months The ages of the persons referred to in the second part were, respectively, 4 months, 4 months, 7 weeks, 1 month

Mr **GROVES** asked the Minister of Health whether, in the case in 1925 and the three cases in 1926 in which certification of vaccination or vaccinia as the cause of death was subsequently withdrawn by the certifying practitioner, such withdrawal was the outcome of correspondence with a representative of Somerset House or an official of his department, and how long after vaccination death took place in these four cases —Mr **CHAMBERLAIN** replied The answer to the first part of the questions is in the affirmative, but I should make it clear that the correspondence undertaken by the Registrar-General in these cases consisted solely of a routine enquiry addressed to the certifying practitioner as to whether he was of opinion that the cause of death was in any way associated with vaccination This is in accordance with the practice which has been followed for many years of addressing inquiries to certifying practitioners respecting any indefinitely certified causes of death As regards the second part of the question, the period between vaccination and death was seven days in two of the cases, and 9 and 17 days respectively in the other two

Fatal Railway Accidents

Mr **DAY** asked the Minister of Transport the number of accidents that had resulted fatally for the 12 months ended to the last convenient date to passengers using or workmen employed on the railways of Great Britain —COLONEL **WILFRID ASHLEY** replied During the year ended 30th Sept last, the number of fatal accidents to passengers using, or workmen employed on, the railways of Great Britain was 71 and 223 respectively

Army Disability Cases

Sir **AYLMER HUNTER-WESTON** asked the Secretary of State for War the number of soldiers discharged from the army during the year 1926 under the headings for wounds and for diseases respectively, and the number that were granted disablement pensions under each heading —Sir L **WORTHINGTON EVANS** replied The total number of disability cases (including those of men already discharged) dealt with by the Chelsea Commissioners during the year 1926 was 2516 105 permanent pensions, and 701 temporary pensions were granted No distinction is made between wounds and injury cases on the one hand and disease cases on the other, and I regret that separate statistics are not available

THURSDAY, MARCH 3RD

Ministry of Pensions Hospitals

Mr **ALLAN PARKINSON** asked the Minister of Pensions whether any hospitals were to be closed during the financial year 1927-28, and, if so, where they were situated —Major **TYRON** replied No arrangements have at present been made for the closure of any hospital during the next financial year The hon Member will, however, realise that the requirements of the Ministry in regard to hospital accommodation can only be determined from time to time by experience of the demand for this form of treatment

Mr **THOMAS KENNEDY** asked the Minister of Pensions what number of Ministry of Pensions hospitals he proposed to retain definitely to ensure that adequate facilities for in-patient treatment were available for so long as such might be necessary —Major **TRYON** replied It is not possible as yet to determine what will prove to be the definite, that is the ultimate, requirements of the Ministry in regard to hospital treatment, nor in what manner those requirements should best be met

Mr **THOMAS KENNEDY** asked the Minister of Pensions what was the total number of hospitals utilised for the treatment of war disabilities and the total bed accommodation provided as at Feb 1st, 1927 —Major **TRYON** replied On the date referred to there were 20 hospitals under the entire control of the Ministry with 4388 beds, and 17 other hospitals, not under the control of the Ministry, whose accommodation was wholly reserved for pensioners containing 2158 beds In addition, 8152 beds were occupied by pensioners under treatment at the charge of the Ministry of Pensions in sanatoria and general or special civil hospitals

Number of War Pensioners

Mr **BECKETT** asked the Minister of Pensions the number of pensioners on Feb 1st, 1926 and 1927 respectively, and the number who had died during that period —Major **TRYON** replied On Dec 31st, 1925 and 1926—the nearest dates to those stated in the question for which figures can be given—the number was 1 058,000 at the earlier date and 1,022,000 at the later date The number of pensioners whose deaths were notified during the year 1926 was 19,550

Small-pox in England and Wales

Mr **DAY** asked the Minister of Health the number of small-pox cases notified in Great Britain for the three months ended to the last convenient date —Mr **CHAMBERLAIN** replied The number of cases of small-pox notified in England and Wales during the 13 weeks ended Feb 19th was 5465, but this figure is subject to revision

Draft Regulations under Lead Paint Act

Mr **VIANT** asked the Home Secretary the dates of the conferences held since Dec 15th, 1926, with representatives of the painting and decorating industry, for the purpose of arriving at agreement in connexion with the circular recently issued for the regulation of the use of white lead in paint, and whether there was unanimity on the points raised in the circular —Sir W **JOYNSON-HICKS** replied I am glad to have this opportunity of correcting a misunderstanding which has arisen in connexion with the explanatory letter issued with the draft Regulations under the Lead Paint Act The letter stated that the terms of the Regulations had been discussed at a series of conferences with the industry at which a complete agreement was arrived at The reference here was to certain conferences which had taken place in 1922 for the purpose of determining what Regulations could be made in the event of the Geneva Convention being ratified, but the statement has apparently been taken in some quarters to imply that conferences had been held subsequently to the passing of the Act, and that the draft Regulations were the outcome of a fresh agreement This was not the case, and no such implication was intended or conveyed The sole object of the circular was to remind the industry of the previous discussions and the agreement then reached, which applied, not only to external painting but also to internal painting during the interval before the prohibition was to take effect Since the issue of the draft Regulations there has been a further meeting with representatives of the industry This resulted, I am informed, in general agreement on the points discussed

Danger from Steam Tractors

Mr **WALTER BAKER** asked the Home Secretary whether he had received representations from the Minister of Transport respecting the danger caused by the emission of smoke, steam, and sparks by steam tractors, and what action he had taken or proposed to take —Sir W **JOYNSON-HICKS** replied Yes Sir, and I propose to issue a memorandum to chief constables reminding them of their powers

Sanitary Accommodation in L C C Schools

Mr **DALTON** asked the President of the Board of Education whether he was aware that in new schools now being built by the London County Council the sanitary accommodation was below that of the Board's Building Regulations of 1914, and whether he would take steps to see that the standard hitherto enforced in respect of the building and remodelling of public elementary schools was preserved —Lord **EUSTACE PERCY** replied I am aware that, in the case of some girls' departments, the County Council have provided rather less sanitary accommodation than that previously required under the Building Regulations of 1914 Authorities are free to suggest a departure from the current practice where it appears to them desirable to do so, but no individual proposal is approved until the Board are satisfied that the accommodation of all kinds to be provided is adequate, having regard to the particular circumstances of the case

Reaction Caused by Vaccination

Mr **WINDSOR** asked the Minister of Health whether he was aware that the medical officer of health for Sheffield had stated that, in spite of the utmost precaution on the part of the vaccinators, vaccination during the recent small-pox scare produced severe reaction, causing temporary illness and a good deal of swelling and pain, whether similar reactions had followed vaccination in other towns, and whether he would stop the issue of vaccine lymph which might cause illness of this kind —Mr **CHAMBERLAIN** replied As regards the first two parts of the question, I would refer the hon Member to answers already given As regards the last part, I am advised that the results obtained from the use in Sheffield of the vaccine lymph issued by the Government Lymph Establishment have been uniformly successful, and among the many thousands of vaccinations performed with this lymph, no case has been reported to my Department in which a severe reaction has been attributed to the lymph. I have no control at present over proprietary lymphs, but regulations for the standardisation of all vaccine lymphs used in this country will come into force when the Therapeutic Substances Act, 1925, becomes operative

Deaths from Influenza

Mr **DAY** asked the Minister of Health the number of deaths in Great Britain resulting from influenza for each of the three months ended to the last convenient date, giving the figures for London and each of the principal provincial towns —Mr **CHAMBERLAIN** replied The figures asked for, so far as they are available for England and Wales, are contained in the tabular statement below

Deaths from Influenza—England and Wales
(Provisional Figures)

Towns of over 200,000 population	During the four weeks ended—			Total
	Dec 25th, 1926	Jan 22nd, 1927	Feb 19th, 1927	
105 Great Towns	249	1055	3292	4596
London	61	423	754	1238
Birmingham	9	20	42	71
Liverpool	9	16	39	64
Manchester	11	22	36	69
Sheffield	5	15	21	41
Leeds	8	10	23	41
Bristol	8	15	146	169
West Ham	3	12	60	75
Hull	1	5	27	33
Bradford	2	3	31	36
Newcastle-on-Tyne	3	5	7	15
Stoke-upon-Trent	1	2	19	22
Nottingham	1	1	91	93
Salford	1	6	16	23
Leicester	—	4	46	50
Portsmouth	3	5	24	32
Cardiff	2	22	52	76

Juvenile Delinquency Commission's Report

Brigadier-General **MAKINS** asked the Home Secretary when the Report of the Commission on Juvenile Delinquency will be available —Sir W **JOYNSON-HICKS** replied I understand that the Committee is likely to present its report towards the end of this month

Diphtheria and Scarlet Fever

Mr **DAY** asked the Minister of Health the notifications of diphtheria and scarlet fever, and the deaths registered from these diseases, for each of the years 1911 to 1926, inclusive —Mr **CHAMBERLAIN** replied The provisional notifications of diphtheria and scarlet fever in England and Wales for 1926 are as follows —Diphtheria Notifications 51,067, deaths 2923 Scarlet fever Notifications 81,670, deaths 667 The corresponding figures for earlier years will be found in the Statistical Review of the Registrar-General

MONDAY, MARCH 7TH

Medical Services in the Army

Sir L **WORTHINGTON-EVANS**, Secretary of State for War, in moving that the House go into Committee of Supply on the Army Estimates, said that he was asking for a total sum of £41,465,000, which was £935,000 less than last year Vote 3, relating to medical services, showed an increase of £60,000 This was in part due to improvements in pay and conditions of service of army doctors For some years past the army medical service had not attracted sufficient young men to maintain the numbers required Complaints had been made by the medical profession, vigorously supported by the British Medical Association, of the inadequacy of pay, of the frequency of moves, and of the length of foreign service tours Many of these complaints seemed to have been well-founded, but though he took steps immediately it was some time before the new conditions could be put into force The Cabinet appointed a Committee to inquire into the pay and conditions of service in the medical branches of the three fighting services, as it was impossible to deal with one without the others Following the report of the Committee, the Royal Warrant of July of last year was issued, under which improved terms and conditions of service had been granted, and the British Medical Association was now recommending service in the Royal Army Medical Corps as a career for young qualified practitioners He still wanted more candidates, however In January last there was a larger entry, but there were still vacancies He wished to draw the attention of newly qualified medical men to two features of the new conditions Those who took up a house appointment could, under certain conditions, get an ante-date to their commissions, in other words, the service in an appointment of a hospital would count as service in the army The other innovation was that, after seven years' service, an officer could retire with a gratuity of £1000 This might be attractive to young doctors who wanted to see a bit of the world before settling down in civil practice, and to whose capital an addition of £1000 might prove extremely useful The army owed much to its medical officers, and he hoped that the reforms now operating would ensure a service as contented as it was efficient

Mr **MACPHERSON** said that praise was due to the Secretary for War because he had considered the position of the Royal Army Medical Corps Those who followed the fate of that service during the war knew what magnificent work it did The War Office were giving a little bounty to these men to come in, and they would come in willingly

Major **GLYN** said that he noticed in the Estimates that the working expenses of seven hospitals, exclusive of salaries and maintenance, amounted to no less than £1,112,000 That seemed to him to be rather a large sum of money for the number of beds which were equipped They all knew the need there was for economy and close inter-working between one service and the other. The Estimates Committee had gone into the matter and one of their recommendations was that there should be closer liaison between the services as regards hospital treatment That had been carried out, and no doubt great economies had been effected, but at the same time it seemed to him that £1,112,000 exclusive of salaries was too high a figure

Dr **VERNON DAVIES** raised the question of pension awards to men who were discharged from the army suffering from consumption He said that the question whether the disease was attributable to the conditions of service was one which it was impossible for the medical board at Chelsea really to decide No one could say when a consumption germ might gain entrance into the human system He understood that certain diseases were held as justifiable causes For instance, if a man had malaria, dysentry, or contracted a bad cold after exposure, or got pneumonia and then developed consumption, it was possible that the medical board would hold that case to be attributable And yet they would find that another man who had not had any of these diseases and who was working at the same time and under the same conditions would also develop consumption, and, therefore, it would be due to the conditions of service There was some other factor in the man himself If the War Office were perfectly logical they could take up the position that no case was due to the conditions of service But they did not take up that position, and their attitude had caused a great deal of dissatisfaction in the country There were three courses which the War Office might take in this matter First of all they might take a definite stand and say that it was impossible to prove in any case that consumption was due to conditions of service, and that therefore they would wipe it out altogether That might be a harsh, but it would be a very logical position Secondly, the War Office might schedule a number of conditions or diseases which could be held to be producing causes of consumption Thirdly —and this was the course which he would prefer—the War Office might institute a system of insurance under which every man in the service could be compulsorily insured against the possibility of contracting consumption. He urged upon the Secretary of State for War that this was a question that required consideration.

Lieut.-Colonel FREMANTLE said that he wished to congratulate the Secretary of State on the action he proposed to take in regard to the Royal Army Medical Corps. This had been a long standing source of trouble since the late war. As a result of the recommendations of a committee which sat on this subject certain improvements were made in the pay of the service last summer, and it was hoped that that would lead to better recruiting for the army medical service. The deficiency which had to be made up was very great. Before the war the establishment of the Royal Army Medical Corps in officers was something like 1000; since the war it was cut down to 900, and there were under 800 officers on the strength last year. This year only 15 candidates had come forward to fill 25 vacancies, so that they were still in a backward position. The Secretary of State in order to meet the case was appealing for short service officers. After a few years when these men had become useful officers they would be entitled to return to civil life with a gratuity. They were increasing, therefore, all their troubles, because they were carrying on with an elderly service increasing always in seniority. That made for great dissatisfaction among the officers, because the older men had to serve over and over again. This was one of the most serious points, to his mind, in the army position at the present time. They were faced with the possibility of a terrible scandal which would go to the root of popular confidence in the army if the country had to engage in a war at the present time. Were they going to be disappointed, as would seem on the surface likely, in view of the poor response so far made to the appeal of the Secretary of State? He was a sufficient optimist to hope that they need not be despondent. At any rate it was too early to judge the results of the new terms which had been offered. But there was one thing that was perfectly certain; they would not get young medical men to take commissions in the fighting services unless those services took direct and vigorous measures to catch hold of them. That could be done now if the campaign was pushed home. He hoped that the best recruiting officers possible would be sent into their own hospitals and medical schools to try and attract young medical recruits into the service. The Secretary of State had mentioned that day that there had been a reduction in the medical services of the Territorial Force in respect of the casualty clearing stations. On the face of it this was a most serious proposal. Great difficulty was caused in the late war because they found it necessary to improvise casualty clearing stations. The first shock of battle meant a large number of casualties, and if the clearing stations did not know their work great difficulties arose. There was not very much required to gather together such stations, but it was just the trained personnel that was necessary. While the framework might be cut down he did hope that the Secretary of State would make arrangements whereby the personnel would continue to be trained so that they might form a nucleus which would be available on the outbreak of war.

Sir L. WORTHINGTON-EVANS, replying to the debate, said that the question raised by Dr. Vernon Davies was one of the most difficult medical questions that could be raised and not one with which that Committee could usefully deal. The hon. member said that it would be logical though harsh to refuse pension in all such cases, but he (Sir L. Worthington-Evans) was glad that they did not do that. It was better to be wrong in some cases than to take up a position of that kind. It was not the fault of the administration that they made mistakes, but it was due rather to the incomplete knowledge of the medical profession in regard to the causes of consumption. He could assure Colonel Fremantle that the War Office was doing its best to follow the course he had suggested. They intended to go round the hospitals and medical schools in order to induce young medical men to enter the army medical service.

Imported Dogs and Rabies

Mr. DAY asked the Minister of Agriculture how many dogs had been imported in accordance with the Ministry of Agriculture's regulations during the six months ended to the last convenient date, and if any cases of rabies had been discovered during the time these animals were in quarantine.—Mr. GUINNESS replied: 388 dogs have been imported from abroad under licenses issued by the Ministry during the six months ended Feb. 28th last. One case of rabies was discovered among these dogs in a dog brought from India.

Ministry of Agriculture and Disinfectants

Lieut.-Colonel FREMANTLE asked the Minister of Agriculture whether, seeing that the test for disinfectants which had now been adopted was considered unsuitable and unreliable by the Admiralty, the War Office, the Air Ministry, and other large purchasers of disinfectants, he would consider the adoption of a more reliable test.—Mr. GUINNESS replied: I am not aware that the test for disinfectants, which the Ministry has adopted for use under the Diseases of Animals Acts is in any sense unreliable. It was adopted after full consideration and scientific advice as being a test conducted under conditions which resemble, as closely as possible, the actual conditions under which the disinfectants prescribed by the Ministry are used in practice.

Colonel FREMANTLE asked if this had been agreed upon in consultation with other Government Departments which were equally concerned in getting a reliable test.—Mr. GUINNESS: The requirements of the other offices are very different from those of agriculture.

Colonel FREMANTLE asked if it would be possible to have this matter reconsidered from the point of view of science, as some equally high authorities are against this radical change.—Mr. GUINNESS: We have prescribed this test on scientific advice supported by the Ministry.

Colonel FREMANTLE asked the Minister of Agriculture if he was aware that brands of disinfectants, which had been approved by the Ministry, were being freely sold to agriculturists in inferior strengths and not labelled in accordance with the Diseases of Animals Disinfection Order, 1926, so that the public were unaware of the proper strength at which to use such agents, and the intention of the statute was plainly defeated; and if he would give the number of samples of disinfectants tested for his department which had been taken from supplies purchased in the open market and the numbers of manufacturers against whom proceedings had been taken for non-compliance with the order.—Mr. GUINNESS replied: The answer to the first part of the question is in the negative. Agriculturists and others required to use approved disinfectants under any Order issued in pursuance of the Diseases of Animals Acts should be careful to see that the preparation they are obtaining for that purpose is labelled clearly as prescribed in the Disinfection Order of 1926. The enforcement of the Orders requiring the use of disinfectants rests with the local authorities. I have no information as to the number of samples of disinfectants taken by those bodies, nor as to the number of prosecutions instituted. No prosecutions have been undertaken by the Ministry.

Colonel FREMANTLE asked if the right hon. gentleman would consider the possibility of his officers taking samples in the open market which could be relied upon instead of samples sent to him which were manifestly cooked-up for the purpose.—Mr. GUINNESS: In the ordinary way the local authorities are quite able to take samples from the open market. It would lead to unnecessary expense to duplicate samples.

School Medical Service

Mr. HARRIS asked the President of the Board of Education what he considered was required to provide a local education authority with a complete medical service; how often a child should be inspected during the elementary school period, and what ailments should be included in the treatment scheme; and what was the standard aimed at by paragraph 6 of circular 1388 when it was laid down by the Board that the first aim of national policy should be the completion of the school medical service.—Lord EUSTACE PERCY replied: A complete school medical service for children in public elementary schools should provide for medical inspection, for following up cases of defect found in the course of inspection, and for medical treatment of defects. Local authorities are required to provide for the inspection of all children on admission to school, on attaining the age of eight, and on attaining the age of 12; provision should also be made for the inspection of special cases and the re-examination of children previously inspected. With regard to the last part of the question, it is not easy to define a rigid standard for a service comprising so many activities, but the hon. Member will find a discussion of the problems involved in chapter V of the Annual Report of the Board's Chief Medical Officer, for the year 1924.

Disability Discharges in the Navy

Lieut.-General Sir AYLMER HUNTER-WESTON asked the First Lord of the Admiralty whether he would inform the House the number of sailors discharged from the Navy during the year 1926 under the headings for wounds and for diseases, respectively; and the number that were granted disablement pensions under each heading.—Lieut.-Colonel HEADLAM (Parliamentary Secretary to the Admiralty) replied: During 1926, 1632 naval ratings and marines were invalided for disease and 93 for injury or wounds. The number who were awarded pensions was 600 approximately. I regret that statistics are not available distinguishing between pensions for injury or wounds and for diseases.

TUESDAY, MARCH 8TH

Vivisection Experiments on Animals

Lieut.-Col. FREMANTLE asked the Home Secretary whether he had received from his inspectors, under the Cruelty to Animals Acts, any reports during the last five years indicating either demonstrations before classes of students or painful experiments of a prolonged and agonising nature on dogs or other animals, and, if so, what action had been taken, and with what result —Capt HACKING replied No, Sir, no such experiments would be permitted and there is no evidence whatever that any have taken place In the case of experiments before students, they are all required to be performed under anæsthetics and the animal must be killed before it recovers consciousness As regards other experiments, all holders of licences who have certificates either dispensing with the requirement to use anæsthetics, or permitting the animals to recover from the preliminary operation under anæsthetics, are subject, in respect of every such experiment, to a special condition known as the pain condition The terms of this condition are printed in the report which is laid by my right hon friend each year before the House and are such as to render "experiments of a prolonged and agonising nature" impossible For many years past the inspectors under the Act have not found any instance of an infringement of this condition, if an inspector did observe any animal to be suffering considerable pain he would at once order it to be killed

Lieut -Col **FREMANTLE** Is my hon and gallant friend aware that specific statements, which he declares to be untrue are being publicly circulated by the National Canine Defence League, and are said to have resulted in a very large number of subscriptions? Can the hon and gallant gentleman do anything to prevent such misleading statements?

Capt **HACKING** · No, Sir, I know that many things are said by many organisations that are not true (loud cheers) and I hope that my answer will get as wide a circulation

Mr **BROMLEY** Can the Under Secretary for Home Affairs say whether some of the inspectors who are put to watch these proceedings have not themselves been vivisectors and are, therefore, in sympathy with them?

Capt **HACKING** No, Sir, that is a very unfair thing to say (cheers) The inspectors carry out their duties very creditably to themselves, to this House, and to the State

Mr **BROMLEY** asked if there had not been such inspectors?

The **SPEAKER** The hon Member ought not to make such suggestions

INFECTIOUS DISEASES IN ENGLAND AND WALES DURING THE WEEK ENDED FEB 26TH, 1927

Notifications —The following cases of infectious disease were notified during the week Small-pox, 438 (last week 346), scarlet fever, 1238, diphtheria, 1039, enteric fever, 35, pneumonia, 3828 (last week 3523), puerperal fever, 41, puerperal pyrexia, 120; cerebro-spinal fever, 16, acute poliomyelitis, 10, acute polio-encephalitis, 1; encephalitis lethargica, 38, dysentery, 11, and ophthalmia neonatorum, 141 No case of cholera, plague or typhus fever was notified during the week

No further cases of small-pox were reported from Cheshire, Lancashire, Lincolnshire, or Glamorganshire Otherwise the disease was limited to the same counties as last week—namely, Derbyshire, 13, Durham, 216, Northumberland, 26, Nottinghamshire, 3, Yorkshire, 145, and Monmouthshire, 35

The Welsh outbreak, which this last figure records, was described in THE LANCET last week, p 506 We are informed that it has now assumed formidable dimensions, roughly 200 cases having been reported since the first case was discovered on Feb 18th While the greatest proportion of the cases are in the Eastern valleys of Monmouthshire, which includes the towns of Abersychan and Blaenavon, cases have been detected over a wide area, including Argoed in the Sirhowy Valley and Aberbargoed in the Rhymney Valley which divides Monmouthshire from Glamorgan A case has also occurred, apparently by casual infection, at Aberdare which is in the middle of the mining valleys of Glamorgan Three cases of small-pox in Newport have been definitely confirmed Chicken-pox has been made notifiable by several authorities in South Wales, and the Welsh Board of Health are urging all authorities to adopt this precaution. The Cardiff City Council are speeding up the building of their new small-pox hospital, and a proposal to use the disused prison at Usk for the isolation of cases of small-pox is causing a certain amount of controversy in Monmouthshire

Deaths —In the aggregate of great towns, including London, there were no deaths from small-pox 4 (1) from enteric fever, 59 (1) from measles, 8 (1) from scarlet fever, 137 (26) from whooping-cough, 41 (11) from diphtheria, 31 (3) from diarrhœa and enteritis under two years, and 1023 (81) from influenza The figures in parenthesis are those for London itself The influenzal deaths for the last seven weeks have thus been 326, 470, 725, 818, 759, 990, and 1023, whilst 898 is the number notified for the week ending March 5th, the figure for London being 69

THE TRAINING OF NURSES FOR THE TROPICS.

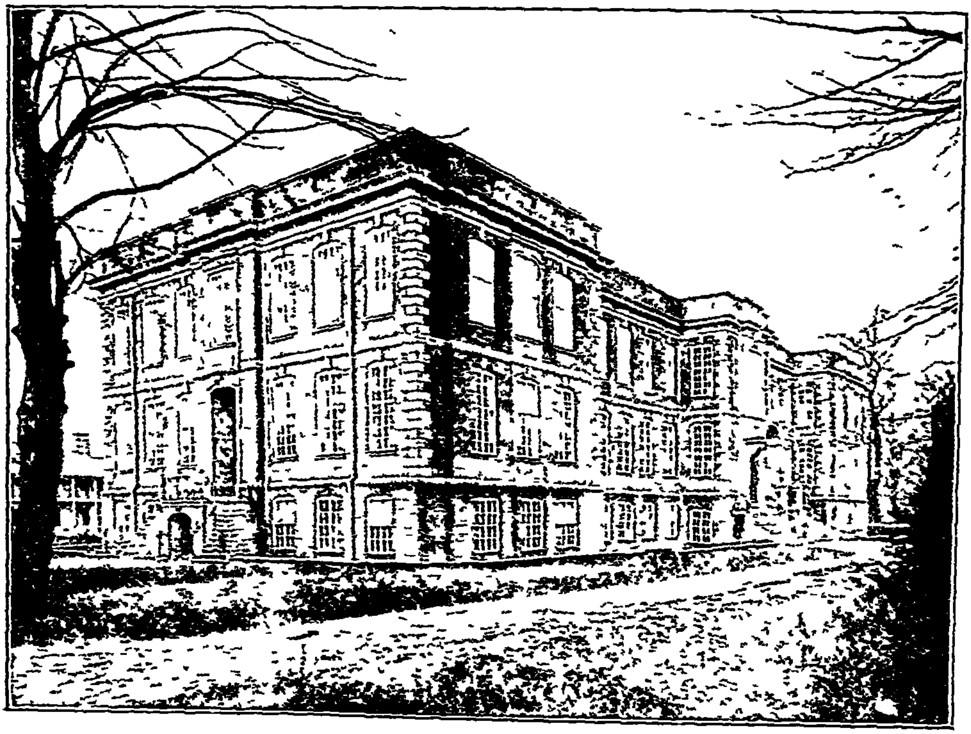
AT a lecture at the College of Nursing on March 8th Dr Philip Manson-Bahr said that a nurse equipped with elementary knowledge of the causation and prevention of tropical disease was an indispensable adjunct to efficient medical work in the tropics Tropical nursing was distinct from ordinary nursing and henceforward would have to be a distinct branch of the profession Nurses in the tropics were often isolated and separated for days at a time, and had to undertake responsibilities such as came to few nurses in this country She must know, inter alia, how to guard against insect-borne and water-borne disease, how to do invalid cookery, how to keep water cool, how to manage native servants, how to use quinine, or, if necessary, inject it, and how to prepare saline solutions, and other necessary drugs, should occasion arise she might be expected to help administer chloroform or do even more dramatic things Microscopic examination of blood and excreta had a far wider range of utility in the diagnosis and treatment of tropical diseases than in other branches of medicine and the tropical nurse would find life more interesting if she had an elementary knowledge of how these things were done At the Hospital for Tropical Diseases, under the ægis of the Seamen's Hospital Society, a course of instruction was given in the elements of tropical nursing The subjects of the course included personal hygiene in the tropics, clothing, exercise, food, alcohol baths, cooking, preservation of food, utilisation of tropical fruits and food, substitutes for milk, avoidance of prickly heat, protection from insect bites and a whole host of other subjects The general lectures dealt with the principal tropical diseases At the end of the course, the nurses were examined in these subjects and a certificate of proficiency was awarded by the Seamen's Hospital Society Staff nurses undertaking nursing abroad could now be taken on the staff of the Hospital for Tropical Diseases for six months and in doing so were free to attend the course of lectures and pass the examination The course was open also for nurses outside the hospital.

Referring to a leading article on Qualifying Examinations for Nurses published in THE LANCET, (March 5th, p 499) Dr Manson-Bahr said that a very high standard of technical knowledge, not always, it might be said, possessed even by medical men, was required by the General Nursing Council A detailed knowledge of anatomy and physiology was not expected of nurses for life in the tropics, nor were they asked to imbibe details of the life-history of disease-bearing parasites which were demanded of doctors qualifying for the higher examinations It was intended however, that they should know the importance of these parasites and the means by which they were spread The knowledge was of a practical nature

THE LATE DR LUMSDEN BELL —Dr James Lumsden Bell, probably the oldest medical practitioner in the East Riding, died at his home at Driffield on March 1st aged 88 years Dr Bell had lived in the town for 60 years He went first to Driffield as a tutor, and after studying medicine in Edinburgh, where he graduated M B and C M in 1880, returned to Driffield and took over a large practice He leaves a widow, two sons, and a daughter.

GIFTS TO THE LONDON HOSPITAL —Mr. Bernhard Baron who recently gave £10,000 to the London Hospital towards the cost of building a new pathological department, has now given a further sum of £25,000 to endow it. It has been found that the new department will cost more than was expected, the lowest estimate being £15,000, and the Rockefeller Foundation has offered the additional £5000 without conditions The Governors have received another generous gift—the freehold site on which the greater part of the hospital stands, from Mr L Abrahams Mr Abrahams bought the site from the City of London for £526 12s

SIR WILLIAM DUNN SCHOOL OF PATHOLOGY, OXFORD.



This new Institute will be opened to-day, Friday, March 11th, by Lord Cave, Lord Chancellor of England and Chancellor of the University of Oxford

(From a photograph by James Soame, 105, St Aldates, Oxford)

A NOTE ON THE ACTION OF A LEAD-SELENIUM COLLOID ON CANCER *

BY A T. TODD, M B EDIN , M.R C.P LOND ,
HON ASSISTANT PHYSICIAN, BRISTOL ROYAL INFIRMARY,
DEMONSTRATOR OF PATHOLOGY, BRISTOL UNIVERSITY

THE article published by Prof Blair Bell on the action of colloidal lead on cancer (THE LANCET, 1925, ii, 793) suggested independent research. It was considered that the addition of selenium might increase the regressive action of lead and that the analgesic properties of this element might lessen the pain of cancer and diminish the pain of lead intoxication.

A lead-selenium colloid was prepared and its toxicity and dosage worked out on animals Then it was used in the treatment of advanced, completely inoperable carcinomas and sarcomas It was not expected that these cases could be cured ; it was hoped that the compound would cause regression and ease pain A small group of diverse cases was treated, for one observer could not hope to follow results of a new remedy except on a small group The results appear to confirm the working hypothesis, for regression has occurred in about 50 per cent of the cases The analgesic action was striking in the one case in which pain was marked ; the absence of colic of any severity, even in cases showing severe blood changes, also encourages the hope that the analgesic action is of value

The regressive action of lead on cancer was postulated from the resemblance of cancer to chorion (Blair Bell) The more malignant the neoplasm the greater is the resemblance to chorion and the greater should be the hope of causing regression The preparation under discussion has marked abortive properties on animals, and with suitable dosage this action is the only obvious one The series is too small for a definite decision, but the preparation has given better results in the more rapidly growing neoplasms

The action on neoplasms having been proved, it is suggested the physician and surgeon can combine in reducing the mortality of cancer by (1) injection after complete operative removal, to kill any possible remaining cell ; (2) reduction of the number of inoperable cases—some of these are due to recent rapid growth from a slowly growing core ; the rapid growth should be vulnerable, the core may be removed; (3) the destruction of the remainder after the mass has been removed by the knife

Brief Summary of the Cases Treated.

(1) Squamous carcinoma of œsophagus Visible carcinoma disappeared, but a recurrence appeared in another place shortly afterwards

(2) Large ulcerated squamous carcinoma of cervix. The growth has disappeared and the cervix appears healthy. No symptoms three months later

(3) Sarcoma of mediastinum Transient improvement after each treatment, considerable relief of pain Sarcoma found to be much necrosed post mortem.

(4) Large squamous carcinoma of tongue ; rapid growth slowed and some relief of pain. Growth persists

(5) Carcinoma uteri, gave up the treatment at an early stage

(6) Squamous carcinoma tongue, large growth with extensive glandular involvement. Large ulcer became smaller, no other effect

(7) Carcinoma of cervix, compressing ureters and extending down vagina. Mass replaced by dense fibrous tissue, no obvious carcinoma. Condition good, but for vesicovaginal fistula

(8) Large fungating spheroidal cell carcinoma breast, firmly fixed to ribs Mass shrank considerably, became small and freely movable Excision of breast. Small scirrhus found

(9) Squamous carcinoma lip Growth appears to be practically stationary No other result.

(10) Papillary ovarian carcinoma with many large metastases all over the peritoneum. *Intestinal* obstruction occurred , at operation only one small nodule of carcinoma remained visible

(11) Carcinoma of tonsil large submaxillary glands. Growth perhaps less and glands softer.

(12) Recurrence of carcinoma of cervix after Wertheim Treatment has just started Mass is much smaller and requires searching for to be found

---

* An abstract of a lecture on the preliminary results of this treatment given to the Bristol Medico-Chirurgical Society on March 9th, 1927

Medical News.

DANGEROUS DRUGS REGULATIONS, 1926 —The Home Secretary has given notice that, in pursuance of the Dangerous Drugs Regulations, 1926, he has appointed two Medical Tribunals—one for England and Wales, and one for Scotland—to which, as occasion arises, may be referred for examination and consideration, any case in which there is, in his opinion, reason to think that a medical practitioner may be supplying, administering or prescribing any of the drugs to which the Dangerous Drugs Regulations apply, either to or for himself or to or for other persons, otherwise than as required for purposes of medical treatment The appointment of these Tribunals was recommended by the *Departmental Committee on Morphine and Heroin Addiction*, presided over by Sir Humphry Rolleston, which reported in January, 1926 (see paras 65 to 75 of the Report) The Tribunals are constituted as follows —*England and Wales* Sir Humphry Rolleston, Bart (chairman), nominated by the General Medical Council, Sir William Hale-White, nominated by the Royal College of Physicians of London, and Dr John Wardle Bone, nominated by the British Medical Association, with Mr E W Hansell, Recorder of Maidstone, as legal assessor *Scotland* . Sir Robert Philip (chairman), nominated by the Royal College of Physicians of Edinburgh, Dr Ashley Watson Mackintosh, nominated by the General Medical Council, and Prof Thomas Kirkpatrick Monro, nominated by the British Medical Association; with Mr John Cowan, K C, as legal assessor Substitute members have also been appointed for each Tribunal to act in the event of the original members being unable to do so

ST BARTHOLOMEW'S HOSPITAL · THE SURGICAL WARDS —A luncheon was given at the Mansion House last week by the Lord Mayor, *Sir Rowland Blades*, to further an appeal for £200,000 on behalf of St. Bartholomew's Hospital The ward blocks, said Lord Stanmore, the treasurer, are more than 200 years old and need "most drastic reconstruction. Some of the operation theatres were erected as lean-to's more than 20 years ago, they are not connected with the wards, and surgical cases have to be taken across the square in all weathers" It is therefore proposed to put up a five-storey building to contain ten new surgical wards of 25 beds each, which would be connected with an operation theatre, and the usual accessories on each floor In the basement there would be an electro-therapeutic department, and on the roof new laboratories Sir Berkeley Moynihan said that on a recent visit to the hospital, he had "found some things that were almost a disgrace—the operation departments were not up to the standard of a first-class hospital in the provinces"

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION —Mr Zachary Cope will lecture for the Fellowship on Common Mistakes in the Diagnosis and Treatment of Acute Abscess, on Thursday, March 17th, at 5 P.M., at the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square On Wednesday, March 16th, at 4 P M, Mr R C Davenport will give a special demonstration at the Central London Ophthalmic Hospital, Judd-street, and on Friday, March 18th, Mr Aleck Bourne will give a special demonstration in gynæcology at the Samaritan Hospital, Marylebone-road The lecture and demonstrations are free to members of the medical profession From March 14th to 25th the Chelsea Hospital for Women will hold a special course in gynæcology, occupying either the mornings or afternoons only and consisting of lectures, demonstrations, and operations (fee £5 5*s*) The Royal National Orthopædic Hospital will hold a two weeks' course from March 21st There will be morning and afternoon sessions, including operations, lecture demonstrations and instruction in the out-patient department, and a special visit will be made to the Brockley Hill County Hospital on Saturday, April 2nd (fee £2 2*s*) Also beginning on March 21st the London Temperance Hospital will give a two-week's course primarily for the benefit of the general practitioner Instruction will be given from 4 30 to 6 P M (fee £1 1*s*) The Queen's Hospital for Children starts a course on March 28th, lasting for two weeks A full all-day programme has been arranged and a special feature is made of showing cases, rather than of lectures, lunch and tea are provided (fee £3 3*s*) From March 28th, for two weeks, the Royal Eye Hospital will give a series of demonstrations during the afternoons on the diagnosis and treatment of the eye (fee £1 1*s*) The Fellowship arranges for practical courses in anæsthetics and obstetrics, and also makes arrangements for clinical assistantships in gynæcology Copies of all syllabuses and of the *Post-Graduate Medical Journal* are obtainable from the Secretary of the Fellowship at 1, Wimpole-street, London, W. 1.

UNIVERSITY OF LONDON Election to the Senate —At the election on May 10th of a medical member of Convocation to the Senate, Mr W McAdam Eccles, surgeon to St Bartholomew's Hospital, is a candidate His experience as a councillor is already great —Mr Walter George Spencer, consulting surgeon to Westminster Hospital and a member of the Council of the University of London Graduates' Association, has been chosen by that body as their candidate for the vacancy Mr Spencer's public services to the profession are well known, and the fact that he has retired from his hospital appointments will make it possible for him to give time to the duties of a Senator

LISTER CENTENARY CELEBRATIONS —Owing to the limited capacity of the House of the Royal Society of Medicine, those wishing to attend the social evening on April 4th, when Sir StClair Thomson will give an address entitled "The Centenary of Lister Recollections by one of his House Surgeons," should apply to the Secretary of the Society for admission cards, whether they are Fellows, Associates, or Members of the Society or not

INTERNATIONAL LISTS OF THE CAUSES OF DEATH —At the request of the Health Organisation of the League of Nations, British, American, French, Italian, and Danish experts will meet on March 14th to study the proposals of a number of Governments, and of an American Committee on the possibility of revising the international list of the causes of deaths These experts will also consider unification of the existing methods of registering infant mortality

RADCLIFFE INFIRMARY —The Governors of the Radcliffe Infirmary at Oxford are considering the urgent need of extensions The hospital requires another surgical ward for women, a women's accident ward, a second operating theatre, and some isolation beds These enlargements would entail the provision of a first-class nurses' home, the accommodation for the nursing and domestic staffs are insufficient and unsatisfactory It is hoped to make an early start with these extensions

BRITISH MEDICAL ASSOCIATION · SCHOLARSHIPS AND GRANTS IN AID OF SCIENTIFIC RESEARCH.—The Council of the B M.A will receive applications as follows ·—

Research Scholarships, a scholarship, known as the Ernest Hart Memorial Scholarship, of the annual value of not more than £200, and three other research scholarships each of the annual value of not more than £150, for research in any subject, including State Medicine, relating to the causation, prevention, or treatment of disease Each scholarship is tenable for one year, commencing on Oct 1st, 1927 A scholar may be reappointed for not more than two additional terms, and may hold a junior appointment at a university, medical school or hospital, provided the duties do not interfere with his work as a scholar

Grants —The Council will also receive applications for grants for the assistance of research in the same directions, preference being given to applicants who propose as subjects for investigation problems directly related to practical medicine

The conditions of the awards of the scholarships and grants will be supplied on application to the Medical Secretary of the Association, Tavistock-square, London, W C 1, and applications for the year 1927-28 must be made not later than Saturday, June 4th, 1927, on the prescribed form, with the names of three references, the form will be supplied by the Medical Secretary

SCOTTISH CRIPPLED CHILDREN —After a year's inquiry an Edinburgh Committee has just reported that there is a "clamant need" for a central hospital for the treatment of crippled children in South-Eastern Scotland, and a public meeting in the capital has accepted their recommendations It is proposed that the institution should be on the outskirts of Edinburgh, that major clinics should be formed at important centres of population, and with minor clinics linked to them, that there should be coöperation between the new special hospital and the existing ones, and that children should be admitted up to 16 The Scottish Board of Health will give grants up to that age There would be a minimum of 75 beds, which with site and equipment, would cost £1000 per bed

RESIGNATION OF A HOSPITAL STAFF —The Committee of Management of the Dorset County Hospital at Dorchester, proposed to alter one of the rules to read as follows "Patients may retain the services of their own medical attendants, but in a case requiring an operation they shall obtain the coöperation of a member of the medical staff at such operation" The whole of the honorary medical and surgical staff of the hospital immediately resigned on the ground that all matters of professional concern should be referred to them for their opinion before any action is taken A few days later the rule was withdrawn for further consideration, and the staff cancelled their resignations

Dr W Essex Wynter will deliver an Emeritus lecture in the Large Lecture Theatre of Middlesex Hospital Medical School, on Friday, March 18th, at 3 P M The subject will be The Study of Local Diseases and Remedies

British Hospitals Association—The annual meeting and conference of this Association has been fixed to take place at Norwich on Thursday and Friday, June 23rd and 24th

Irish Medical Schools and Graduates' Association—The annual dinner of this Association will be held on Thursday, March 17th, at 7 30 P M, Sir W I de C Wheeler, the president, in the chair Vice-Admiral Sir Frederick Field will be the principal guest

Middlesex Hospital—Prince Arthur of Connaught, chairman of the hospital, has received £1000 from Lieut-Colonel Beddington in response to Mr J A. Berner's offer to give that sum towards the new block of paying wards for the hospital, if nine others would do the same

King Edward's Hospital Fund for London—Hospitals situated within 11 miles of St Paul's which may wish to participate in grants for 1927 made by the Fund must apply before March 31st to the hon secretaries at 7, Walbrook, E C 4 Applications will also be considered from convalescent homes which are within the above area or which, although situated outside it, take a large proportion of patients from London

South Devon and East Cornwall Hospital—The pressure upon this Plymouth hospital, which serves a district extending from Clovelly on the north to Land's End on the south, has become so severe, that it is proposed to extend it by providing 70 additional beds, a number of paying beds, and a new out-patient department It will then be the largest voluntary hospital in the West of England

The New Southend Hospital—So many agencies are at work raising money for the erection of the proposed new General Hospital at Southend-on-Sea, that the committee of the new hospital fund is requiring that the organisers of all efforts in aid shall obtain official approval of their plans, and that all printed matter shall bear the official badge of the fund, together with an indication of the proportion of the receipts which are to go to the hospital

Vaccinations at Southport—The Chairman of the Health Committee stated at a meeting of the Town Council that the first case of small-pox appeared on Jan 8th, and that altogether there had been 51 cases, and only four of them had been vaccinated, and those were vaccinated in childhood The last case recorded was on Feb 18th, and only 14 cases remained in the hospital Over 15,000 people have been vaccinated since the outbreak

Medical Society of London—The 154th anniversary dinner of the Medical Society of London was held at the Grand Hotel, London, on Monday, March 7th, the President of the Society, Sir Humphry Rolleston, in the chair The toast of the Society was proposed briefly by Sir John Rose Bradford, who laid stress on its seniority and on the individuality which it had always preserved In a witty reply the Chairman pointed to the strong surgical bias which had recently marked the official lectures, and announced that the sessions this year would be closed by an address from the great American surgeon, Harvey Cushing The vitality of the Society, he considered, made it a young though an old institution, and in proof of his words he referred to the increasing membership and the good attendance at the meetings The toast of the Visitors was proposed by Dr Walter Carr, who said that three lines were open to a speaker in his position—that of general reflection, that of categorising all the guests present and mentioning their merits—an invidious and lengthy process, and that of referring to one guest in the more spacious manner Lt.-Col J R Lord, President of the Royal Medico-Psychological Association, had been selected as the victim Colonel Lord, in his reply, suggested that such was the growing influence of psychology in medicine that his special branch, so far from being the Cinderella, might be held as the superior of many sections of their science, and he pointed out that the famous Quaker physician, who founded the Medical Society of London—Lettsom—was a great psychiatrist, for, realising 150 years ago the effect upon mental development which the system of slavery must entail, he had been led to emancipate all the slaves on his family property in the West Indies, although at the time that he did so he possessed no other private pecuniary resources The health of the President was proposed by Mr J E H Roberts, who ran rapidly through Sir Humphry Rolleston's varied posts and performances, mentioning at the end of the imposing list the fact that he had played for his hospital in a winning cup team Suitable acknowledgments of the toast by the secretaries of the Society, Dr F G Chandler and Mr V Z Cope, closed a pleasant evening

University of Liverpool—Lord Derby, Chancellor of the University, has agreed to add during the next seven years an annual donation of £1000 to the £500 per annum he is already contributing to the University funds

University of Aberdeen.—On Wednesday, March 23rd, the University of Aberdeen will confer the honorary degree of LL D upon Sir William Milligan of Manchester, and Sir Frederick Gowland Hopkins, Professor of Biochemistry at Cambridge

Royal Aeronautical Society—A lecture, entitled Man and the Machine will be delivered by Group Capt M Flack, at 6 30 P M, on Thursday, March 10th, at the Royal Society of Arts, 18, John-street, Adelphi, London, W C

Biochemical Society—The annual general meeting will be held on Friday, March 18th, at 4 30 P M, in the Department of Physiology and Biochemistry, University College, Gower-street, W C

Metropolitan Asylums Board—A three months course on clinical practice and hospital administration, for the Diploma of Public Health, will be given at the North-Eastern Hospital, St Ann's-road, Tottenham, N 15, by Dr F H Thomson, the medical superintendent, on Mondays and Wednesdays at 4 45 P M and alternate Saturdays at 11 A M, beginning on Monday, April 11th Application should be made to the Clerk to the Board, at Victoria Embankment, London, E C 4

Chelsea Clinical Society—The next meeting of this Society will be held at The Rembrandt Hotel, Thurloe Place, London, S W 7, on Tuesday, March 15th, at 8 30 P M preceded by dinner at 7 30 P M. Dr Russell Andrews, Dr F J McCann, and Sir Bruce Bruce-Porter will take part in a discussion on Professional Regrets

International Society of Medical Hydrology
On March 3rd the President (Dr Gustave Monod) and Madame Monod received members and guests at a conversazione in the rooms of the Medical Society of London Those present were drawn from ten different countries and included the Minister for Latvia and representatives of the French and Italian Embassies and of the Czech Legation A lecture was read by Mr Yates for Mr Lewis Abbott of Hastings on the History of Silica, which was illustrated by specimens shown on the epidiascope An address was given by Prof Desgrez who brought greetings to the Society from the Institute of Hydrology of the Faculty of Medicine of Paris and gave a short description of the teaching of hydrology in France and the work of research and standardisation carried on by the Institute After acknowledging Prof Desgrez's tribute to the Society the President called upon Mr W A Appleton (Secretary of the General Federation of Trade Unions) to make a statement on the attitude of the Unions towards rheumatism in industry Mr Appleton is a member of the Society's British committee on rheumatism which is seeking to establish a clinic in London in pursuance of the scheme suggested by the Ministry of Health The evening ended with a violin recital by Madame J van Breemen

The Chief Inspector of Factories announces a vacant appointment for a Certifying Factory Surgeon at Leiston Suffolk

Births, Marriages, and Deaths.

BIRTHS

DOUTHWAITE.—On Feb 27th, at 'Carlingford," Worthing Sussex, the wife of Dr A H Douthwaite, of a daughter

JACKSON —On Feb 27th at Knowle, Fareham, Hants, the wife of J L Jackson M B , *of a son*

NASH.—On Feb 28th, at Winn road, Southampton, the wife of Major E L F Nash, R A.M C , of a son

SMITH —On Feb 28th at Sherborne House, Gloucester, the wife of Dr E F Smith, of the Chestnuts, Stroud, Gloucestershire, of a daughter

TWORT —On March 1st at The Wilderness, Camberley the wife of Dr F W Twort The Brown Institution, of a daughter

MARRIAGES

CAHILL—BERESFORD —On March 1st, at the Church of St Thomas of Canterbury Woodford, Henry Bernard Martin Cahill L D S R.C S (Eng) to Doris Maud elder daughter of Walter A Beresford of St Mary s Croft, Wanstead, Essex

HARGREAVES—MERRYWEATHER.—On Feb 23rd, at Mandeville Jamaica, George McNeill Hargreaves M D , to Margaret daughter of the late Ernest Merryweather

DEATHS

DANCY —On Feb 28th at Duke's avenue Chiswick Horace Michael Dancy, M R C S , L R C P , late of Ramsgate, Kent, aged 74

GREENE.—On March 5th at Kingsnorth gardens Folkestone John Alan Campbell Greene, M R C S , L R C P , M C , late of Woodsley road, Leeds

PEGLER —On Feb 26th at Snayle's Tower Exeter Louis Hemmington Pegler, M D , M R C S , L.R C P , late of Harley street, London W

PRESTON —On March 1st at Wyndham House Ryde, I of W , Lionel Litchfield Preston M B B S aged 62

SCALES —On Feb 28th at Redcourt, Adams road, Cambridge, Francis Shillington Scales M D

N B — A fee of 7s 6d is charged for the insertion of Notices of Births, Marriages, and Deaths

CREMATION IN GREAT BRITAIN —A slow but steady increase of cremation in the whole of Great Britain is shown by comparison of figures for 1922 and 1926 the totals being 2009 and 2877 respectively

Notes, Comments, and Abstracts.

RHEUMATIC INFECTION OF CHILDHOOD.*

BY CAREY F COOMBS, M D , F R C P LOND ,

PHYSICIAN WITH CHARGE OF OUT-PATIENTS, BRISTOL GENERAL HOSPITAL

I

THE series of lectures to which this discourse belongs serves to remind us of the labours of a man who spent his life and strength in organising the fight against disease Of Sir Edwin Chadwick and his fellow-workers may we most truly say, " Other men laboured, and we have entered into their labours " From them we have inherited, not only comparative freedom from zymotic disease, but also the apparatus for combating that which remains I trust that I may be able to show you that in three respects at least the infection to which our attention is to be directed this afternoon must be fought with the weapons that Chadwick did so much to create housing control, care for the health of the elementary school-child, and coördination of the machinery already in being

Definition

The label " rheumatic " covers a rather wider area when it is used by the public than it does in the hands of the medical profession It is to the narrower sense that I shall limit it , I shall follow the definition of the rheumatic diseases assumed by the Ministry of Health in its recent Report,[1] with one important difference The inquiry on which that report was based was restricted to the insured population so that children were excluded This necessarily excluded from the inquiry a majority of patients suffering from what is best called " the rheumatic infection " It has been well said, I think by Dr F J Poynton, that this disease assumes its typical form in childhood attacking adults less often and in a form in which the articular aspects are atypically emphasised

The Manifestations of Infection

The fact is that the rheumatic fever of adults, fortunately less common than it was, offered so dramatic a picture of suffering that it quite threw into the shade the insidious yet far more dangerous cardiac lesions of childhood It is mainly to the London school of physicians that we owe our present and more accurate view, that which sets the cardiac lesions in the centre of the stage and treats the other manifestations as of less importance The cardiac inflammation is one of several manifestations of the activity of this infection, the four chief of which are carditis, polyarthritis, chorea, and subcutaneous nodes All these reactions are similar in their essentials if we allow for the local colour prescribed by the nature of the tissue infected

These changes are most easily studied in the heart, but reach their extreme expression in the subcutaneous node If we watch their evolution in one of the seams of connective tissue that traverse the cardiac muscle, we shall detect the first change in some small blood-vessel Its lining cells swell and multiply, it becomes the centre of a brisk inflammation, and after being sealed by clotting is more or less wholly destroyed The mobile defensive cells that are called from a distance seem to disappear from the picture leaving the inflammatory field in possession of cells, for the most part local in origin As these again recede, a characteristic picture is revealed a background of fibrin embedded in which lie large cells with many nuclei, and cells destined to become fibrous tissue. This, in turn gives way to a permanent but inconspicuous scar If the muscle cells of the heart wall be examined, it will be found that they have not escaped Changes similar in type to but less in degree than those of diphtheria can be seen The cardiac muscle has been attacked by a poison which entered through its own proper blood-vessels and spread thence to all parts If the dose of poison is concentrated enough it may kill outright More often the patient survives but with permanent disabilities, for an inflammatory reaction of a kind similar to that seen in the interstices of the heart muscle has been set up in the serous tissues that clothe that muscle and assist it in its work The valves that lie within the heart and are essential to its value as a pump are thickened and deformed, and at least fail to help, often actually hindering, the work that the heart has to do Often, also, the pericardial sac by which the heart is enveloped is partially or wholly ruined The two layers which should slip over each other so smoothly as to nullify the friction of the beating heart against its surroundings are welded together into a fibrous mass, and thus once more a permanent disability is laid on the heart

---

* Lectures on the Causes and Prevention of Rheumatism, delivered under the Chadwick Trust The first lecture (of which this is the first half) was given on March 3rd 1927

[1] Ministry of Health Report No 23, 1924

Nor is this all The infection which has attacked the heart is seldom content with one of these raids Usually it comes again and again, so often in many cases that its inroads assume the character of a prolonged occupation It is true that as age advances these raids tend to become less frequent Yet the combination of permanent mechanical disability and recurrent drenchings with poison is very deadly Every year claims its victims, especially the first 10 or 15 years from the date of the primary infection There is, moreover, a steadily increasing degree of disablement, which ultimately becomes complete in those who escape death

The other manifestations are less deadly, but one of them, an inflammation of the brain and its coverings, is responsible in the aggregate for a great deal of interference with the education of the growing child It is exhibited in the form of chorea, or St. Vitus's dance, which may keep the child out of school for weeks or months, and recur from time to time Joint pains seldom afflict the rheumatic child severely, and their chief significance is to act as a warning of the probable coexistence of a cardiac inflammation.

Of the subcutaneous node I must say a word or two In the severest cases of rheumatic infection in childhood these nodes are to be found in the parts where but little fat intervenes between skin and bone, for example, over the elbows and knees They are not painful and seldom tender, and are likely to be overlooked unless they are deliberately searched for Their genesis is exactly the same as that of the inflammatory spots in the cardiac muscle that I have already described, although they are on a larger scale, a blood-vessel becomes inflamed and closed, and around it a mass of new cells is formed, which evolves into a small scar in the course of a few weeks Although these nodes are only seen in the severest cases of rheumatic infection, when they do occur they are more characteristic of that infection than any other of its manifestations, for there is no other infection that produces their like

Disablement and Recovery.

This, then, is the disease of which we are hearing so much—an inflammation of the heart which tends to become chronic and to inflict lasting disability on those who survive its earliest onslaughts From a study of statistics several facts emerge first, that if recovery takes place at all it must necessarily be in the early stage, second, that the disease claims a large proportion of its victims also in that earlier stage, third, that of those who, though uncured, survive that stage few reach the age of 50, finally, that those who do survive are seriously disabled

One thing is encouraging The results of a follow-up of over 600 cases which was carried out with the aid of a grant from the Medical Research Council, showed a surprising number of apparent recoveries even among children whose hearts had undoubtedly been damaged I feel sure that we shall get far better results when we have learnt to treat this disease as patiently and thoroughly as we treat, for instance, tuberculosis of bones and joints Our views on the treatment of chronic and persistent infection are moving in the direction first pointed by the open-air treatment of tuberculosis To the application of rest, carefully controlled and if necessary prolonged, under conditions affording a maximum of sunlight and fresh air and good food, has in recent years been added a tendency to alternate rest with occupation as a therapeutic agent, and these principles have found a wide application in the treatment of rheumatic heart disease in America In this country there is a growing belief in the country hospital-school for the treatment of crippling disease in childhood, and in the benefits to be derived from such institutions as these the cardiorheumatic child is destined to share

But here we are chiefly concerned with means for the prevention of rheumatic heart disease First, we must realise that the disease is already decreasing This is the experience of most general hospitals, and, moreover, an examination of the mortality records for Bristol for the years 1876–1913 showed quite clearly that there was a fall in the annual death-rate of this disease There are three other facts that emerged from this enquiry which will, I believe, interest you First, it was seen that though the death-rate from this disease was decreasing, it was decreasing less rapidly than the general death-rate did during the same period Second, the years which saw large semi-rural areas brought into the city and therefore into these records, were followed by an acceleration in the fall of the rheumatic heart disease death-rate The inference is that if a city's population is diluted by the addition of country districts, the percentage of that population attacked by rheumatic heart disease will be smaller Third, by a comparison of these mortality records with records of hospital cases in which the diagnosis had been checked by post-mortem examination, I came to the conclusion that Bristol, a city of a quarter of a million people on an average of the period of inquiry, lost between 70 and 80 lives per annum from this disease

Taking the population of Great Britain at forty million, we may deduce the annual loss from this disease as about 12,000 This would include deaths from such forms of valvular disease as are generally admitted to be rheumatic in origin—namely, mitral stenosis and aortic regurgitation in persons under 30 A rough estimate of the mass of disablement inflicted on our nation by this form of heart disease is to be found by allowing an average of five years' disablement to each case This brings the number of persons permanently disabled by it up to 60,000 in any given year

Predisposing Factors

Some of the conditions predisposing to this disease are so generally admitted, that it will be enough to state them Of my cases of rheumatic heart disease two-thirds arose between the ages of 5 and 15 The disease falls a little more often on girls than on boys, in somewhere about the proportion of three to two A hereditary predisposition appears to be traceable in about 50 per cent Probably it exists potentially even where it does not reveal itself actually The disease is relatively rare in tropical countries, falling with particular intensity on this country and Northern Europe Its incidence is heaviest in the winter months, as was seen in a curve plotted from the Bristol figures, using only those in which the disease appeared to have been acute and therefore of recent origin

These are causal circumstances over which we have no control Now we must turn to three or four factors which are of more practical importance because they might be susceptible of modification At the same time they must be received with a little caution, as we cannot claim that any one of them is established beyond controversy In the first place, I have already mentioned urbanisation, but let me at once disarm criticism by saying that we are at present trying to organise, in the West of England, an inquiry into the incidence of the disease in urban versus rural communities By this means we hope to secure valuable evidence, and the question may be decisively settled one way or the other Second, there is the poverty factor There are various views on this, but I am sure I am expressing the sense of the majority in laying stress on the contrast exemplified in my own experience, which shows that 50 per cent of the cases of heart disease admitted to hospital are rheumatic, as against only 25 per cent of those seen in private practice The evidence collected by Dr Vincent Coates and Dr R E Thomas[3] from their inquiry in Bath went to show that the incidence of the disease was heaviest in the better-class industrial suburbs, and apparently less among the very poor Be that as it may, it is quite certainly a rare disease among the well-to-do

This brings us to another point, that of housing My inquiries in Bristol gave no support to the view that certain houses were so heavily infected as to injure one inmate after another In only eleven houses had more than one death from rheumatic heart disease occurred, and in none of these had there been more than two deaths But another Bristol investigation, carried out recently by Dr R A Askins and Dr J Morrison, into the condition of the home of a number of elementary school children with rheumatic heart disease, showed, conclusively to my mind, that dampness in houses had something to do with the origins of rheumatic infection This inquiry was most carefully conducted Dr Morrison himself visited the houses and made a thorough inspection In Bath Dr Coates and Dr Thomas noted a coincidence between the distribution of the disease, and houses built on alluvial soil These facts, together with others collected by Dr Reginald Miller in Paddington and Dr A P Thomson in Birmingham, have persuaded me that there is a connexion between damp in houses and rheumatic infection, although my own research into mortality records had previously led me to think otherwise

(*To be concluded*)

AN ARGENTINE MEDICAL JOURNAL.

UNDER the name of *Cordoba Medica* Dr Antonio Novarro issues the first number of a periodical which is intended to give a monthly survey of the whole field of medicine whether in the Argentine or abroad It opens with articles on the syndrome of coronary occlusion, on the presternal muscles and on the plastic surgery of the nose The beginning is promising, if modest, and the journal should prove stimulating to medical work in Cordoba

[3] THE LANCET, 1925, ii, 326

A NEW METHOD OF COMBATING OLD AGE

Prof E Steinach has published in the January number of the *Medical Journal and Record* details of a new minor operation which can be carried out in patients who have already been subjected to bilateral vasotomy The results of vaso-ligature are admittedly temporary and once the operation has been performed it is impossible again to have recourse to this method of stimulating the activity of the interstitial cells

The new operation may be described as "albugineatomy" Through a small opening in the scrotum the testicle is exposed, and with the help of an assistant kept in its position After selecting a place in the tunica albuginea with very few blood-vessels, an incision of from 2–3 cm. is made The edges of the incision separate, and spontaneously a small piece of testicular substance protrudes This piece, about the size of the kernel of a date or a small olive, is smoothly cut off with scissors, and after ligaturing any vessel that bleeds, the albuginea is sutured together with a fine needle and catgut Finally the tunica of the testicle and the scrotal wound is closed

Steinach explains the rationale of the operation as follows The tightly stretched albuginea keeps the whole convoluted mass of the seminiferous tubules under pressure. Like wires in a bundle, the tubules are pressed closely together leaving very small interstices for the interstitial cells Diminution of this pressure by permitting a separation of the tubules encourages the growth of the interstitial cells in the interstices In addition, the local trauma inflicted on the seminiferous tubules by the removal of the protruding mass of testicular tissue leads to a degeneration of the tubules in the region of the operation, and to a proliferation of interstitial cells Both these factors cause an increase of interstitial cells and reactivation of the internal secretion of the testes and this in turn leads to a stimulation of the whole endocrine system According to Steinach, the biological consequences of albugineatomy in senile animals are similar to those obtained by vaso-ligature So far this method has only been carried out on a few human subjects, but it may, be regarded as a possible repetition therapy for those cases in which bilateral vaso-ligature has already produced positive results

USEFUL WELFARE WORK

ARRANGEMENTS are being made by the Post Office authorities, through the British Spas Federation, whereby postmen and certain other members of the Post Office staffs will be able to obtain a course of spa treatment at any of the British spas at special inclusive terms Owing to the nature of their work postmen are, perhaps, especially subject to rheumatism, and in future any who have been medically recommended for spa treatment will no longer be prevented from obtaining that benefit on account of the cost The spa authorities have also offered to give every assistance in their power in helping to find suitable accommodation In view of the attention now being given to the question of making spa treatment available for insured persons suffering from rheumatic diseases, it is interesting that a great Government Department, probably the largest employer of labour in the country, should anticipate the National Insurance Scheme This useful piece of welfare work will be appreciated by those whom it is designed to help, and the taxpayer, at no cost to himself, stands to benefit by the more speedy return of the postman to duty and his increased efficiency

MIXTURES OF BUTTER AND MARGARINE

THE improvement of the methods available for distinction between butter oleo margarine, and vegetable margarine is a matter which interests not only the analyst but the medical man responsible for the dietaries of organised communities, whether armies, schools or *hospitals* It is important for the latter to know whether his charges are being fed on butter which is easily digestible and fairly rich in vitamin A, on beef olein, which is less satisfactory in these respects, or on mixtures largely composed of coconut and palm kernel oils, which are fats deficient in vitamin content, and not easily digestible by many people The use of hydrogenated oils is also to be watched for Reichert Polenske, and Kirschner have respectively furnished standardised means of measuring the acids volatile in steam, the insoluble acids volatile in steam, and the volatile acids which yield soluble silver salts If the assumption that definite values for each of these data could be assigned to the fats in question, we should be still in the position of having only three parameters for four unknowns, and further assumptions would be needed before a taste for simultaneous equations could be indulged Actually there is no difficulty in determining whether or not butter is substantially pure, or in distinguishing between oleo and nut-margarine It is when it is desired to ascertain the composition of mixtures that difficulties arise The current number of the *Analyst* contains papers by G D Elsdon and P Smith, and C H Manley on this subject Elsdon and Smith, who base their work on the Polenske and Reichert values alone quote Mr H Droop Richmond's estimate of the scope of their results He says "The most that can be expected from your results are first, it is possible to distinguish coconut oil and palm kernel oil, second, that when the two exist in the same mixture and the percentage of coconut oil is well under 30 per cent, an approximate idea of the relative proportions of the two oils can be deduced within about 15 or 20 per cent either way" The determination of butter fat in margarine is probably more trustworthy Mr Manley introduces a new value which is a measure of that (greater) portion of the soluble fatty acids which goes into aqueous solution when the saponified butter is acidified with sulphuric acid The process and a modified Kirschner process based on it appears to be useful for sorting butters and margarines, which is all that is claimed for them It is probable that the most useful development of the examination of these materials from the physiological point of view would be the application of some of the colorimetric methods of estimation of the growth-promoting vitamin The trustworthiness of some of these when compared with experiments on animals appears to be well established The economic aspect of a knowledge of the actual constituents of a mixture of fats will, however, continue to furnish incentive for improvements in analytical methods

CUTANEOUS ADSORPTION

A PAPER by Dr Antonio Fernandez in the *Semana Medica* for Jan 13th gives the result of some experimental work on the phenomena of cutaneous adsorption—i e, the union, whatever be its nature, between epidemal cells and a substance applied to their surface, such union not being chemical, nor solution in the strict sense, nor intracellular

The experiments show that the application of phenol resorcin, and β-naphthol, in solution or as an ointment, results in adsorption, the scales of the skin treated with them are found to give up the substances used in varying proportions, the quantity being greater with an ointment than with a solution Even after 24 hours, distinct traces of phenol were found in the scales removed from the areas treated The method used was simply to apply the substance with proper precautions to the interdigital spaces, when, after they had been left for 24 hours, some scales were removed and placed in tubes with water or with appropriate reagents In all cases the results were positive

The facts are interesting so far as they go, but they are too scanty to admit of any general deduction The research might well be extended to other substances, and also to showing how long the substance adsorbed remains in the cells of the epidermis before it is either absorbed or resecreted by the skin Variation in adsorption in different persons and different pathological conditions could also be studied and might give valuable results

THE DETECTION OF BILE-SALTS IN URINE

THE classical test devised by Matthew Hay for the detection of bile-salts in the urine has been investigated by Surgeon Lieut -Commander W I Gerrard,[1] who finds that it remains by far the best and easiest way of demonstrating their presence The test depends on the capacity of urine to sustain flowers of sulphur scattered over its surface The sulphur will float on the surface of normal urine but will sink to the bottom if the *surface-tension* has been reduced by bile-salts in solution To secure the best results, says Commander Gerrard, a standard technique must be used The sulphur should be shaken from a pepper-pot held by a clamp 2 5 c cm above the surface of the urine which should be contained in a rectangular cell This cell should be illuminated by a source of light shaded from the observer's eyes and shining into the urine at right angles to the direction in which he is looking The sulphur sinks at once, he says when the bile-salts are in a strength up to 1 in 10,000 If the vessel is gently shaken the presence of bile-salts can be detected after two minutes in a dilution of up to 1 in 10 000, by waiting ten minutes falling of the sulphur may be seen where salts are present in dilutions up to 1 in 120,000 Using this technique, Commander Gerrard found that in a seris of cases of salvarsan jaundice there was a greater disturbance in the elimination of bile-salts than of bile and pigments In many cases there was true dissociation in that although both bile-salts and pigments were present in the blood only the former appeared in the urine In so called catarrhal jaundice this dissociation was seldom detected, and he believes that the occurrence of bile-salts in the urine without bile pigment is a sign of definite hepatic damage

---

[1] Journal of the Royal Naval Medical Service, July 1926

PHYSIQUE OF THE JEWS

In a recent lecture to the West End Jewish Literary Society, Dr Lyle Cameron described the Jews as, on the whole, a healthy and sturdy people Of the factors which had preserved them health had been one of the most important, and Jewish racial characteristics were evidently dominant or they would have been superseded long ago by those of the nations with which they had from time to time sojourned, and with whom there must have been admixtures of blood

Jews, he said, possessed a high degree of natural immunity to bacterial disease Ordinary septic infections troubled them but little They had a high resistance to malaria, and were the best suited of all white races to live in malarial districts

It had long been held that the Jewish race contributed more cases of insanity than any other Studies by A Pilez in Vienna, and C F Beadles in London, supported this view In 1880 Spitzka, in America, came to the conclusion that the various forms of insanity occurred in nearly the same proportions in the Anglo-Saxon, Teutonic, and Hebrew races In Germany in 1909 Sichel, whose deduction was based on the Frankfort Hospital for the Insane, found relatively more Jewish inmates than the corresponding percentage of the Jewish population of Frankfort This, however, only held for certain groups of mental disorders The other types revealed a smaller percentage of Jews than non-Jews Amaurotic family idiocy was almost, if not entirely, confined to Jews, and they had always been considered very prone to diabetes The view that tuberculosis was rare and cancer common amongst Jews required modification. It had not been definitely shown that they were more susceptible to tubercle than other races In the course of the discussion which followed, Dr G E Spero referred to the effects of dietary laws upon physique, and Dr David Nabarro pointed out that Jewish abstemiousness as regards alcohol heightened their resistance So long as the Jewish race adhered to the Mosaic Laws concerning food they were likely to avoid some of the diseases to which non-Jewish inhabitants of the same countries were prone Dr Nabarro regarded the nervous system and the mentality of the Jew as of a high order, it was, he thought, more likely to break down under stress, a fact for which persecution had been partly responsible

HOP-PICKING IN KENT DURING 1926

From time to time in comments on the annual reports for Kent we have referred to the inadequate arrangements made for the reception of the hop-pickers We have now received from Dr S N Galbraith, medical officer of health for the South-West Kent united health area, a special report on the measures adopted for the health of the hop-pickers during 1926 The report shows that the county council and local authorities, the Southern Railway, the Farmers' Union, and voluntary organisations have combined to form with representatives of the Ministries of Agriculture and Health, a committee for supervision of the work. This committee meets at Maidstone, under the chairmanship of Mr J A. Spender The magnitude of the problem is shown by the fact that last season 25,000 pickers were conveyed by rail to stations in South-West Kent, and that over 45,000 visitors were carried at the week-ends to the Kentish fields A very large number also travel by road Dispensaries are established throughout the district by many organisations, including the British Red Cross Society, the Salvation Army and Medical Missionary Societies Cases of sickness are admitted to various hospitals, and creches are established for ailing babies Certain occupational diseases are mentioned such as hop rash (237 cases), hopper's eye (95 cases), and hopper's gout (87 cases) Septic sores are common There were only ten cases of infectious disease notified The free supply of diarrhœa mixture by the Maidstone and Tonbridge rural district councils was discontinued without any increase of diarrhœa Many new improved huts have been constructed and many new cookhouses Water supplies and conveniences have been improved The inspection of the food has also received close attention For example, in the Maidstone Rural District 200 lb of meat and 50 lb of fish were seized, and in Tonbridge town a motor van containing 1125 lb of unsound meat on its way to be sold to the pickers was condemned On some farms prizes are awarded to the pickers who keep their huts and belongings in the best condition There is some trouble from water wastage, and efforts are being made to provide anti-waste taps for the hopper camps Accommodation of the 50,000 week-end visitors is very difficult; one farmer estimates that 500 visitors come to his farm at the week-end The lack of cookhouse accommodation is a source of trouble on most farms, and so is the danger from fires Dr A. C Parsons of the Ministry of Health says "From observations and enquiries made in the camps in the past two seasons, it is clear that a built-up fireplace and chimney are essential to a suitable cookhouse" The by-laws require one fireplace to 15 pickers

Eight deaths of hop-pickers or their children were registered Of these, six were those of infants, including three from gastro-enteritis and one from burns The report records very creditable effort by the official and voluntary agencies concerned

CAN TAR CAUSE PULMONARY CANCER?

An inquest was held on March 5th by the Manchester coroner, Mr C W W. Surridge, on a gas retort worker aged 59, who had been employed by the Manchester Corporation for 26 years This man was forced to leave his work in March of last year, and subsequently underwent an operation His duties at the gasworks were to keep the mains clear of tar and to charge up retorts after they had been scraped, he had worked a good deal with tar The Medical Inspector of Factories, Dr S A Henry, was present, and the corporation was represented It was stated that the deceased had not worn gloves whilst at work with tar, since he left, gloves had been provided For the Corporation, it was pointed out that all the men were invited to report any black spots or warts noticed on their bodies Medical examination was always available, free of charge, and everything possible was provided to keep the employees clean Dr Norman Kletz described the result of the post-mortem examination. A healed scar was found on the scrotum, due to a previous operation for epithelioma, but this disease had apparently been completely eliminated Death was due to a primary growth in the lung In reply to the coroner, Dr Kletz stated that there was no connexion between the previous disease of the scrotum and the lung He was not in a position to say that the growth in the lung could not have been caused by inhaling the fumes of tar, but he had never heard of such a case In returning an open verdict, the coroner said that there was no doubt that if epithelioma were treated in its earliest phase a complete cure resulted. Death had resulted from heart failure, due to the pulmonary growth, and he was satisfied that there was no connexion between the cause of death and the earlier disease of the scrotum. Only time and further investigation could show whether a cancerous growth in the lung could be produced by working amidst tar fumes The coroner added "Years ago it was not known that there was any connexion between disease of the scrotum and external contact with tar Now that has been proved to be so, and it may be in days to come that the inhalation of tar fumes will show some connexion with growths in the lungs It is not sufficiently established as yet, and I propose to return an open verdict"

PERSISTENT BOILS

To the Editor of The Lancet

Sir,—I shall be much obliged to any medical man suggesting a cure for persistent boils in a woman of 33, she has been a martyr to them for more than eight years Vaccines, extraction of all her teeth, injections of manganese, and other drugs too numerous to mention have been tried

I am, Sir, yours faithfully,
W L C.
March 5th, 1927

A CASE OF PREGNANCY FOLLOWING POLYGLANDULAR THERAPY

To the Editor of The Lancet

Sir,—A patient X (aged 30 and married for seven years) was seen by me about six months ago complaining of nervousness, dizziness, and "rounds of hot flushing" Her menstrual history was very irregular, sometimes she went for three months without any menstrual discharge There was no anæmia, but she had been told some years earlier that she would always be sterile as her uterus and ovaries were not developed

On pelvic examination I found a very small undeveloped uterus and the ovaries could only just be felt with great difficulty I kept the patient on ovarian tablets for a month with apparently no result I then gave her polyglandular tablets containing a mixture of thyroid, thymus, pituitary, suprarenal, mammary, ovarian substance, and cerebrin. Two tablets were given three times a day, and the following week she said that "the rounds of hot flushing" had disappeared and she slept much better Two months later her uterus and ovaries were found to have increased in size, and at the time of writing all her signs and symptoms point to an early pregnancy This opinion has also been arrived at by my senior colleague, Dr A C J Wilson

My conclusions in this case are that the patient was entering upon a premature menopause caused by a lack of balance of the endocrines resulting in maldevelopment of the uterus and ovarian insufficiency None of the other ductless glands showed any obvious atrophy or overdevelopment —I am, Sir, yours faithfully,

A. A Masser, M B, Ch B
Penistone, Sheffield, March 3rd, 1927

An Address
ON
SOME PROBLEMS IN THE TREATMENT OF NEUROSYPHILIS.

Delivered before the West Kent Medico-Chirurgical Society on March 11th, 1927,

BY J L BIRLEY, M D OXF , F R C P LOND.,
PHYSICIAN TO OUT PATIENTS, ST THOMAS'S HOSPITAL,
CONSULTANT PHYSICIAN TO THE ROYAL AIR FORCE

THE feelings of anyone who to-day ventures to express an opinion on this subject must be very different from those which would have been experienced a generation ago At that time it was generally agreed that mercury and the iodides were indicated in all forms of neurosyphilis with the exception of tabes and general paresis, and that the latter conditions, even supposing that they were syphilitic in origin, were not amenable to any therapy, specific or otherwise To-day, on the other hand, these comfortable beliefs have been rudely shaken by a body of knowledge which has been accumulated so rapidly that our powers of assimilation have been seriously strained and our equilibrium disturbed Conflict and controversy, however, are the handmaidens of progress, for although they are apt to engender extreme views at the outset, these in turn are prone to beget more moderate and stable opinions This paper can make no claim to solve the riddles of neurosyphilis; it represents merely an attempt to sift the known from the unknown, on the principle that the sense of one's ignorance is a much more useful thing than the sense of one's knowledge So little knowledge is absolute, and so great is the desire of the human mind to believe that it is

In the present century we can identify three important landmarks in the history of syphilis First, the discovery in syphilitic lesions of the *Spirochæta pallida* by the zoologist, Schaudinn, in 1905, and the subsequent finding of the parasite in the nervous tissues of paralytics and tabetics by Noguchi, secondly, the complement-fixation test published by Wassermann in 1908, and thirdly, the introduction in 1909 by Ehrlich of the spirochæticide salvarsan and of the allied compounds which have since replaced it Of the first of these discoveries it may be said that it has shed light on what was previously dark, of the second and third, that they have opened a door by which those who will may enter and explore the hidden mysteries of syphilitic disease

Two guiding principles must govern any discussion of the treatment of neurosyphilis The first is one of general application—viz, that all rational therapy must be based on an adequate comprehension of the nature of the lesions to be treated The second is more particular, and lies in the recognition which is becoming increasingly evident that the nervous system is, or may be, affected with greater frequency and at a much earlier stage of the proceedings than was hitherto supposed These two factors together indicate that our conceptions of neurosyphilis will be incomplete unless we have a clear idea of the changes induced in the organism from the time of infection until either the disease is eradicated or the patient dies The problems underlying neurosyphilis have become more and more identified with the broader problems of syphilitic infection in general, subject only to those peculiarities of structure and function which distinguish nervous from other tissues One practical result which has emerged from the recognition of this early involvement of the nervous system is that the observation and treatment of these early phenomena, many of them unaccompanied by subjective or objective evidence of nervous disease, are carried out by the syphilologist to the exclusion of the neurologist. To raise any fundamental objection to this procedure would savour of pedantry, for at this early stage the object of treatment—namely, the destruction of the spirochæte—can be achieved in a very large majority of cases, and the choice of drugs and dosage can confidently be left to the unfettered discretion of the syphilologist But the fact that these early stages of neurosyphilis have now come within the orbit of venereal departments has so stimulated their appetites that there is now a further tendency for neurosyphilis, and, in fact, for syphilis generally, in all its stages to become isolated from neurology and general medicine respectively This development I regard as in some respects unfortunate, since the problems underlying neurosyphilis are so diffuse that they merit the combined attention of workers in many fields and from varying angles

EARLY MENINGEAL REACTION

In the primary stage of syphilis, even before the Wassermann reaction in the blood has become positive, a lymphocytosis may be observed in the cerebro-spinal fluid in a small percentage of cases. The frequency of pathological changes in the fluid increases through the late primary stage (Wassermann reaction in blood positive) up to the so-called secondary stage (acute syphilis), until it reaches, in the absence of treatment, something like 50 per cent in the second and third half years from the time of infection. Speaking generally, it may be said that during the whole period of the first 18 months the essential change in the fluid is an excess of cells, and that a positive Wassermann reaction increases pari passu with the length of time which has elapsed since the primary infection As compared with the pleocytosis, however, a positive Wassermann reaction in the fluid is relatively rare during the first 18 months. For example, in 1314 cases of syphilis examined by Fildes, Maitland, and Parnell a pleocytosis of five cells or more per cubic millimetre were found in the cerebro-spinal fluid as follows —

Type of case	No of cases	Pleocytosis	Fluid W R +
Primary (blood W R negative)	144	21 (14 %)	0
Late primary (W R +), no rash, up to 18/12 from infection	371	80 (21 %)	12 (3 %)
Secondaries present or history of, (W R +) up to 18/12 from infection	512	160 (30 %)	35 (6 %)

The great majority of these cases had had no treatment or very inadequate treatment, and presented no clinical evidence of nervous disease. The changes in the cerebro-spinal fluid are due to a meningeal inflammation, and indicate that the meninges are reacting in a diffuse sort of manner to the presence of the spirochæte, much in the same way as the skin is reacting The condition, in fact, is in the nature of a meningeal rash, and like the cutaneous eruption, shows a tendency to spontaneous resolution and repair But acute syphilis is not a disease of the covering or supporting tissues only, since at an early stage the virus has become generalised by the blood stream and the parasites may penetrate into all the body tissues, including the parenchymatous, more specialised, tissues of various organs, such as the liver, testis, and central nervous system And just as a degeneration of the essential hepatic cells, recognised as an acute yellow atrophy, may be observed in the acute stages, so also, if rarely, a parenchymatous degeneration of nerve-cells and neuroglia may occur within a few months of infection (acute encephalitis) The question, therefore, arises, What is the significance of the early meningeal reaction in relation to late parenchymatous syphilis?

Significance of the Reaction

That the meningeal reaction is a reaction to parasites within the meninges, and not a reaction à distance can hardly be disputed Do the parasites

PHYSIQUE OF THE JEWS

IN a recent lecture to the West End Jewish Literary Society, Dr Lyle Cameron described the Jews as, on the whole, a healthy and sturdy people Of the factors which had preserved them health had been one of the most important, and Jewish racial characteristics were evidently dominant or they would have been superseded long ago by those of the nations with which they had from time to time sojourned, and with whom there must have been admixtures of blood

Jews, he said, possessed a high degree of natural immunity to bacterial disease Ordinary septic infections troubled them but little They had a high resistance to malaria, and were the best suited of all white races to live in malarial districts

It had long been held that the Jewish race contributed more cases of insanity than any other Studies by A Pilcz in Vienna, and C F Beadles in London, supported this view In 1880 Spitzka, in America, came to the conclusion that the various forms of insanity occurred in nearly the same proportions in the Anglo-Saxon, Teutonic, and Hebrew races In Germany in 1909 Sichel, whose deduction was based on the Frankfort Hospital for the Insane, found relatively more Jewish inmates than the corresponding percentage of the Jewish population of Frankfort This, however, only held for certain groups of mental disorders The other types revealed a smaller percentage of Jews than non-Jews Amaurotic family idiocy was almost, if not entirely, confined to Jews, and they had always been considered very prone to diabetes The view that tuberculosis was rare and cancer common amongst Jews required modification It had not been definitely shown that they were more susceptible to tubercle than other races In the course of the discussion which followed, Dr G E Spero referred to the effects of dietary laws upon physique, and Dr David Nabarro pointed out that Jewish abstemiousness as regards alcohol heightened their resistance So long as the Jewish race adhered to the Mosaic Laws concerning food they were likely to avoid some of the diseases to which non-Jewish inhabitants of the same countries were prone Dr Nabarro regarded the nervous system and the mentality of the Jew as of a high order, it was, he thought, more likely to break down under stress, a fact for which persecution had been partly responsible

HOP-PICKING IN KENT DURING 1926

FROM *time to time in comments on the annual reports for Kent* we have referred to the inadequate arrangements made for the reception of the hop-pickers We have now received from Dr S N Galbraith, medical officer of health for the South-West Kent united health area, a special report *on the measures adopted for the health of the hop-pickers* during 1926 The report shows that the county council and local authorities, the Southern Railway, the Farmers' Union, and voluntary organisations have combined to form with representatives of the Ministries of Agriculture and Health, a *committee for supervision of the work.* This committee meets at Maidstone, under the chairmanship of Mr J A. Spender. The magnitude of the problem is shown by the fact that last season 25,000 pickers were conveyed by rail to stations in South-West Kent, and that over 45,000 visitors were carried at the week-ends to the Kentish fields A very large number also travel by road Dispensaries are established throughout the district by many organisations, including the British Red Cross Society, the Salvation Army and Medical Missionary Societies Cases of sickness are admitted to various hospitals, and creches are established for ailing babies Certain occupational diseases are mentioned such as hop rash (237 cases), hopper's eye (95 cases), and hopper's gout (87 cases) Septic sores are common There were only ten cases of infectious disease notified The free supply of diarrhœa mixture *by the Maidstone and Tonbridge* rural district councils was discontinued without any increase of diarrhœa Many new improved huts have been constructed and many new cookhouses Water supplies and conveniences have been improved The inspection of the food has also received close attention For example, in the Maidstone Rural District 200 lb of meat and *50 lb of fish* were seized, and in Tonbridge town a motor van containing 1125 lb of unsound meat on its way to be sold to the pickers was condemned On some farms prizes are awarded to the pickers who keep their huts and belongings in the best condition There is *some trouble* from water wastage, and efforts are being made to provide anti-waste taps for the hopper camps Accommodation of the 50,000 week-end visitors is very difficult, one farmer estimates that 500 visitors come to his farm at the week-end The lack of cookhouse accommodation is a source of trouble on most farms, and so is the danger from fires Dr A. C Parsons of the Ministry of Health says "From observations and enquiries made in the camps in the past two seasons, it is clear that a built-up fireplace and chimney are essential to a suitable cookhouse." The by-laws require one fireplace to 15 pickers Eight deaths of hop-pickers or their children were registered Of these, six were those of infants, including three from gastro-enteritis and one from burns The report records very creditable effort by the official and voluntary agencies concerned

CAN TAR CAUSE PULMONARY CANCER?

AN inquest was held on March 5th by the Manchester coroner, Mr C W W Surridge, on a gas retort worker aged 59, who had been employed by the Manchester Corporation for 26 years This man was forced to leave his work *in March of last year, and subsequently underwent* an operation His duties at the gasworks were to keep the mains clear of tar and to charge up retorts after they had been scraped, he had worked a good deal with tar The Medical Inspector of Factories, Dr S A Henry, was present, and the corporation was represented It was stated that the deceased had not worn gloves whilst at work with tar, since he left, gloves had been provided For the Corporation, it was pointed out that all the men were invited to report any black spots or warts noticed on their bodies Medical examination was always available, free of charge, and everything possible was provided to keep the employees clean Dr Norman Kletz described the result of the post mortem examination A healed scar was found on the scrotum, due to a previous operation for epithelioma, but this disease had apparently been completely eliminated Death was due to a primary growth in the lung In reply to the coroner, Dr Kletz stated that there was no connexion between the previous disease of the scrotum and the lung He was not in a position to say that the growth in the lung could not have been caused by inhaling the fumes of tar, but he had never heard of such a case In returning an open verdict, the coroner said that there was no doubt that if epithelioma were treated in its earliest phase a complete cure resulted Death had resulted from heart failure, due to the pulmonary growth, and he was satisfied that there was no connexion between the cause of death and the earlier disease of the scrotum. Only time and further investigation could show whether a cancerous growth in the lung could be produced by working amidst tar fumes The coroner added "Years ago it was not known that there was any connexion between disease of the scrotum and external contact with tar Now that has been proved to be so, and it may be in days to come that the inhalation of tar fumes will show some connexion with growths in the lungs It is not sufficiently established as yet, and I propose to return an open verdict."

PERSISTENT BOILS

To the Editor of THE LANCET

SIR,—I shall be much obliged to any medical man suggesting a cure for persistent boils in a woman of 33, she has been a martyr to them for more than eight years Vaccines, extraction of all her teeth, injections of manganese, and other drugs too numerous to mention have been tried

I am, Sir, yours faithfully,
W L C.

March 5th, 1927

A CASE OF PREGNANCY FOLLOWING POLYGLANDULAR THERAPY

To the Editor of THE LANCET

SIR,—A patient X (aged 30 and married for seven years) was seen by me about six months ago complaining of nervousness, dizziness, and "rounds of hot flushing" Her menstrual history was very irregular, sometimes she went for three months without any menstrual discharge There was no anæmia, but she had been told some years earlier that she would always be sterile as her uterus and ovaries were not developed

On pelvic examination I found a very small undeveloped uterus and the ovaries could only just be felt with great difficulty I kept the patient on ovarian tablets for a month with apparently no result I then gave her polyglandular tablets containing a mixture of thyroid, thymus, pituitary, *suprarenal, mammary, ovarian substance,* and cerebrin Two tablets were given three times a day, and the following week she said that "the rounds of hot flushing" had disappeared and she slept much better Two months later her uterus and ovaries were found to have increased in size, and at the time of writing all her signs and symptoms point to an early pregnancy This opinion has also been arrived at by my senior colleague Dr A C J Wilson

My conclusions in this case are that the patient was entering upon a premature menopause caused by a lack of balance of the endocrines resulting in maldevelopment of the uterus and ovarian insufficiency None of the other ductless glands showed any obvious atrophy or overdevelopment —I am, Sir, yours faithfully,

E PARENCHYMATOUS NEUROSYPHILIS

International Congress of Medicine held
on in 1913, a discussion took place on the
of the Condition termed Parasyphilis A few
prior to the meeting Noguchi had succeeded
nonstrating the spirochæte in the brains of
tics, and the older theories were beginning to
The toxic-degenerative theory of para-
is introduced by Fournier in 1894 assumed
tissues long exposed to the toxins of syphilis
give way under the strain and undergo a
ly progressive decay, and that in general para-
the degenerative products exert an irritant
t on the supporting tissues of the brain with
equent changes in these structures This view
ned to be warranted by: (*a*) the resistance of
asyphilitic conditions to antisyphilitic remedies:
the absence of the spirochæte from the lesions:
the long interval between infection and the onset
parasyphilis, and (*d*) the apparent "systemic"
ure of the pathological changes Those who are
posed to the conception of "parasyphilis" and
ist on the fundamental pathological unity of all
philitic processes point out that (*a*) the resistance
treatment is due to a failure on the part of arsenical
parations to penetrate to the deeper tissues which
bour the spirochæte; that (*b*) the spirochæte has
n demonstrated in the brains and cords of paralytics
l tabetics; that (*c*) the long interval is due to the
w development of increased tissue susceptibility;
and that (*d*) the changes are not strictly "systemic"
t all and their peculiar distribution can be explained
y increased opportunities for spirochætal invasion
njoyed by certain territories of the nervous system
opposed to others

Before considering these points a little more fully,
e further objection which is frequently advanced
inst the toxic theory may be noted—viz that the
n is "hypothetical" The question arises What
eant by the term "hypothetical toxin"? I am
aware for example that the toxin of pneumococcal
tions has yet been proved to have any phenomenal
y but even supposing that this unawareness is due to ignorance on my part, I should still feel justified in believing in its existence for on no other hypothesis can I explain the phenomena of pneumonia or of pneumococcal peritonitis But as regards parasyphilis the toxin theory does not seem to explain the observed facts for it is difficult to conceive inter alia of a toxin operating over a long period on such vulnerable structures as the essential elements of the nervous system without producing any symptoms until the final collapse On these grounds—viz. incompatibility with the observed facts and readier explanation by a quite different hypothesis—the theory may be inadmissible, but it must be pointed out that its repudiation does not necessarily entail the view that spirochætes never produce toxins

With respect to the other objections to Fournier's conception of parasyphilis there can be no dispute as to the presence of the spirochæte in the brains of paralytics but there is some difference of opinion as to their distribution At first they were found only in the substance of the brain and in intimate relation to the ganglion cells whereas more recently they have also been observed in the perivascular tissues and even within the lumen of the vessels They can only rarely be discovered in the meninges or the meningeal vessels In tabes their demonstration is more difficult, but Richter has recently described them in the posterior roots These points are of importance in connexion with treatment.

ARE THE LESIONS "SYSTEMIC"?

Tabes, general paralysis and "tabetic" optic atrophy have long been regarded as systemic diseases but the more we know of their morbid anatomy the less systemic do they become The changes in general paralysis of the insane are not limited to a selective degeneration of the cells of the frontal lobes; on the contrary pathological alterations in the mesoblastic elements are frequently present alterations which are indistinguishable from those met with in much earlier manifestations and are gummatous in character Both sets of changes are referable to the heightened susceptibility of the tissues both parenchymatous and mesoblastic, by virtue of which they react excessively to the presence of a relatively small number of spirochætes

The condition of affairs in tabes is complicated by the fact that there seems to be no unanimity as to the essential lesion responsible It is generally agreed that the exogenous fibres of the posterior root system are affected and not the endogenous but the localisation and nature of the lesion are still matters of controversy According to Richter the essential lesion is a chronic granuloma of the extramedullary portion of the posterior roots between the cord and the posterior root ganglion affecting first the nerve-sheaths and later the nerve-fibres which slowly degenerate The short and medium fibres degenerate before the long fibres and the degeneration never extends beyond the primary neuron—i e, as far as the arborisations round the cells at the base of the posterior horns in the case of the shorter fibres and the cells of the medullary nuclei in the case of the long fibres This secondary degeneration leads to (or is associated with) proliferation of the supporting neuroglia which results in a degeneration of the endogenous fibres of the posterior columns so that finally we have the text-book picture of the disease—viz almost total degeneration of the posterior columns But the picture is apt to be misleading unless it is realised that the posterior column degeneration is secondary to events taking place in the posterior roots, and that even the latter are very unequally affected For example the trigeminal upper thoracic lower lumbar and upper sacral roots are far more frequently and earlier involved than the intervening roots It has been suggested that this curious distribution is due to the passage of the spirochæte or its toxin along the perineural lymphatics drained by those peripheral areas in which "secondary" lesions are most common—e g face always gain entrance to the essential nervous elements by traversing the meninges, and do they do so at this early stage? The answer is probably Yes in both cases The French school have especially insisted on the fact that a meningitis, as evidenced by an increase of cells and of globulin, always precedes involvement of the nervous parenchyma, and dence is accumulating that in late neurosyphilitic onditions, such as tabes, the fluid, though not infrequently normal when the patient comes under observation, has at some previous time shown pathological changes Further, unless the spirochæte gains admittance to the nervous tissue proper during the acute stage, it has to be assumed that in latent syphilis the parasite wanders from some distant focus until it comes to rest in the brain or cord There is no evidence of such migration, in fact, it would seem that such nests of spirochætes as are not destroyed in the acute stage settle down into some intimate relation with the tissues, by virtue of which they become fixed and the condition remains "latent" over long periods

If this reasoning is correct, we are forced to the following conclusions (*a*) that the meningeal reaction is in itself not direct evidence of the penetration of the parasite into the essential parenchyma, (*b*) that where such penetration occurs it is probably associated with a transient [illegible] that access to the nervous elements occurs in the acute stage, although clinical evidence thereof may be deferred for many years What we require and do not possess is some means of determining in any given case the lodgment of the parasite in the nervous parenchyma apart from its coverings and blood-vessels If, on the other hand, pathological changes in the fluid are not a sine quâ non for deeper penetration of the parasite, we should have to admit that a persistently normal fluid during the first two years was no security against the subsequent development of general paralysis of the insane or tabes

THE COURSE AND SIGNIFICANCE OF CHANGES IN CEREBRO-SPINAL FLUID

Having noted the existence of these early meningeal phenomena, we now have to consider the changes which they undergo and the significance of those changes Here we are on much more difficult ground First it must be recalled that the meningeal reaction is part of the acute stage of syphilis, the period, that is to say, at which the organism is rapidly mobilising all its mechanisms of defence until a climax is finally reached, culminating in a vigorous humoral and cellular reaction characterised by the rapid production of antibodies and the destruction, partial or complete, of the invading parasites This stage would seem to be followed by a period of relative exhaustion, during which the sensitiveness of the tissues undergoes a rapid diminution and any spirochætes which have escaped destruction relapse into a state of tranquillity as judged by clinical standards In view of the natural resistance of the tissues it is easy to understand that an abnormal fluid in the acute stage may spontaneously revert to normality or can be brought to normality by treatment, in fact, this appears to happen in something like 85 per cent of the cases, and in a large proportion of such cases the fluid remains normal permanently. It is the refractory minority which provides us with our difficulties, for we have no means of knowing what individuals will recover spontaneously or under treatment without observation and trial If it were possible to measure individual immunity, to anticipate the extent of individual capacity to react, we could separate at the outset the refractory minority from the tractable majority

In this connexion som [illegible] on the treatment of acute syphilis [illegible] themselves We can omit from consi [illegible] th stage before the Wasse [illegible] positive in the blood, su [illegible] cure can [illegible] with me [illegible] themselves for treatment within six months of infection all with positive blood Wassermanns, and that after a course of treatment, represented by X, we obtain 85 cures, and that by considerably increasing the dosage by an amount represented by Y we cure the remaining 15 When the next batch of 100 similar cases present themselves for treatment, it would be clearly inadmissible to prescribe an X+Y course of treatment with a view to obtaining 100 per cent of cures, since by doing so we should run the risk of overtreating 85 per cent The dosage of arsenical preparations usually considered adequate has shown a tendency to increase very materially during the past decade, and although much of the increase is *undoubtedly* justifiable and productive of good results there seems to be a danger of its passing beyond the bounds of judicious therapy, and that this excess of zeal is based to some extent on a misinterpretation of the value of statistical data

To return to the changes in the cerebro-spinal fluid, various possibilities are open to consideration (1) The fluid remains normal throughout, here we can confidently exclude any risk of neurosyphilis, early or late (2) There is a pleocytosis which disappears spontaneously or under treatment within six months. Most of such fluids remain normal permanently, and according to Dreyfus, if they are still normal one after treatment has ceased, neurosyphilis is improbable (3) The fluid after becoming normal reverts to 'positive' again within a few months. Such fluids can with difficulty be brought back to normal again by intensive treatment, but they show a tendency to relapse (4) There is a feeble meningeal reaction or possibly none at all the parasite, however, gradually acquires better conditions of growth and after a lapse of many years, pathological changes appear in the fluid which may be permanent What is the proportion of those in the last three groups who develop neurosyphilis is unknown, nor do we know with any completeness the changes which the fluid undergoes in the years preceding the advent of such conditions as tabes or general paralysis of the insane All that seems reasonably certain is the fact that fluids which have reverted from "negative" to "positive," as well as those which become positive many years after infection, are altered by treatment with the greatest difficulty or not at all We may regard these differences of behaviour in the cerebro-spinal fluid as an expression of different degrees of individual reaction to the spirochæte

TREATMENT OF MENINGO-VASCULAR SYPHI

Before passing on to the consideration of chronic syphilis, mention should be made of the fact that the nervous system may suffer severe damage in the acute stage as a result of pathological changes invo [illegible] primarily the meninges and blood-vessels At [illegible] stage, however, by energetic treatment the virus [illegible] be destroyed, the cerebro-spinal fluid brought ba [illegible] normal, and the patient restored to health apart [illegible] such residual palsies as may have been determ [illegible] by the destructive character of the initial les [illegible] As a general rule, it may be stated that the sh [illegible] the interval which has elapsed from the pri [illegible] infection, the better the prognosis, and that [illegible] meningo-vascular syphilis is rarely followed in [illegible] years by tabes and even more rarely by g [illegible] paralysis

To discuss the details of treatment of acute ne [illegible] syphilis would be out of place, but a few br [illegible] principles may be mentioned Our object at t [illegible] stage is to sterilise the meninges as rapidly as possib [illegible] and for this purpose stabilarsan or neosalvarsan [illegible] essential I am, however, convinced that me [illegible] properly used, as, for example, by inunction, is st [illegible] an indispensable adjunct, and is slightly preferab [illegible] to bismuth, although I must confess to have [illegible] insufficient experience of the more recent bismu [illegible] preparations such as bismoxyl, which are free fro [illegible] he objections which attached to some of the earli [illegible] Lastly, the iodides in large doses up to gr [illegible] y or even more may sometimes effect a m [illegible] when arsenic and mercury have failed, and they should form part of the treatment in the intervals of arsenical administration

ALLERGY AND CHRONIC SYPHILIS

It is well known that the lesions of late (chronic) syphilis present certain clinical features which differentiate them from the lesions of the acute stage A consideration of these peculiarities reveals the fact that the differences are of degree rather than of kind, and depend on an alteration in the reactive condition of the tissues concerned This alteration is in the nature of a greatly increased sensitiveness to those spirochætes which have escaped destruction in the acute stage The phenomenon is called allergy In this hyperallergic condition the tissues react excessively to a small number of spirochætes, and the reaction is characterised by a great tendency to proliferation and degeneration Where the mesoblastic, supporting, bactericidal tissues are chiefly involved, the result is excessive fibrosis, strangulation of blood-supply, and gummatous necrosis Where, on the other hand the more specialised, highly differentiated, and consequently less resistant cells, whether visceral or nervous, are concerned, the result will be degeneration This increased susceptibility of the tissues is developed after the subsidence of the acute stage and would appear to be dependent on the intoxication of the tissues which is necessarily associated with destruction of spirochætes in large numbers, and the consequent liberation of toxin and its fixation by the tissues It must however, be remembered that if late parenchymatous neurosyphilis is to be interpreted in terms of allergy, it has to be admitted that this increased susceptibility of the tissues can develop in the absence of any clinical signs of acute syphilis; for in tabes and general paralysis of the insane a history of secondaries is the exception and not the rule

LATE PARENCHYMATOUS NEUROSYPHILIS

At the International Congress of Medicine held in London in 1913, a discussion took place on the Nature of the Condition termed Parasyphilis A few months prior to the meeting Noguchi had succeeded in demonstrating the spirochæte in the brains of paralytics, and the older theories were beginning to wobble The toxic-degenerative theory of parasyphilis, introduced by Fournier in 1894, assumed that tissues long exposed to the toxins of syphilis finally give way under the strain and undergo a rapidly progressive decay, and that in general paralysis the degenerative products exert an irritant effect on the supporting tissues of the brain with consequent changes in these structures This view seemed to be warranted by (*a*) the resistance of parasyphilitic conditions to antisyphilitic remedies, (*b*) the absence of the spirochæte from the lesions, (*c*) the long interval between infection and the onset of parasyphilis, and (*d*) the apparent "systemic" nature of the pathological changes Those who are opposed to the conception of "parasyphilis" and insist on the fundamental pathological unity of all syphilitic processes, point out that (*a*) the resistance to treatment is due to a failure on the part of arsenical preparations to penetrate to the deeper tissues which harbour the spirochæte, that (*b*) the spirochæte has been demonstrated in the brains and cords of paralytics and tabetics; that (c) the long interval is due to the development of increased tissue susceptibility, that (*d*) the changes are not strictly "systemic" all, and their peculiar distribution can be explained increased opportunities for spirochætal invasion oyed by certain territories of the nervous system pposed to others

fore considering these points a little more fully other objection which is frequently advanced t the toxic theory may be noted—viz that the is "hypothetical' The question arises What t by the term "hypothetical toxin'? I am for example that the toxin of pneumococcal s has yet been proved to have any phenomenal but even supposing that this unawareness is due to ignorance on my part, I should still feel justified in believing in its existence, for on no other hypothesis can I explain the phenomena of pneumonia or of pneumococcal peritonitis But as regards parasyphilis, the toxin theory does not seem to explain the observed facts, for it is difficult to conceive inter alia of a toxin operating over a long period on such vulnerable structures as the essential elements of the nervous system without producing any symptoms until the final collapse On these grounds—viz, incompatibility with the observed facts and readier explanation by a quite different hypothesis—the theory may be inadmissible but it must be pointed out that its repudiation does not necessarily entail the view that spirochætes never produce toxins

With respect to the other objections to Fournier's conception of parasyphilis, there can be no dispute as to the presence of the spirochæte in the brains of paralytics, but there is some difference of opinion as to their distribution At first they were found only in the substance of the brain and in intimate relation to the ganglion cells whereas more recently they have also been observed in the perivascular tissues, and even within the lumen of the vessels They can only rarely be discovered in the meninges or the meningeal vessels In tabes their demonstration is more difficult but Richter has recently described them in the posterior roots These points are of importance in connexion with treatment

ARE THE LESIONS "SYSTEMIC"?

Tabes, general paralysis, and "tabetic' optic atrophy have long been regarded as systemic diseases, but the more we know of their morbid anatomy the less systemic do they become. The changes in general paralysis of the insane are not limited to a selective degeneration of the cells of the frontal lobes, on the contrary, pathological alterations in the mesoblastic elements are frequently present, alterations which are indistinguishable from those met with in much earlier manifestations and are gummatous in character Both sets of changes are referable to the heightened susceptibility of the tissues both parenchymatous and mesoblastic, by virtue of which they react excessively to the presence of a relatively small number of spirochætes

The condition of affairs in tabes is complicated by the fact that there seems to be no unanimity as to the essential lesion responsible It is generally agreed that the exogenous fibres of the posterior root system are affected and not the endogenous but the localisation and nature of the lesion are still matters of controversy According to Richter, the essential lesion is a chronic granuloma of the extramedullary portion of the posterior roots, between the cord and the posterior root ganglion, affecting first the nerve-sheaths and later the nerve-fibres which slowly degenerate The short and medium fibres degenerate before the long fibres, and the degeneration never extends beyond the primary neuron—i e as far as the arborisations round the cells at the base of the posterior horns in the case of the shorter fibres, and the cells of the medullary nuclei in the case of the long fibres This secondary degeneration leads to (or is associated with) proliferation of the supporting neuroglia which results in a degeneration of the endogenous fibres of the posterior columns so that finally we have the text-book picture of the disease—viz almost total degeneration of the posterior columns But the picture is apt to be misleading unless it is realised that the posterior column degeneration is secondary to events taking place in the posterior roots and that even the latter are very unequally affected For example, the trigeminal upper thoracic lower lumbar, and upper sacral roots are far more frequently and earlier involved than the intervening roots It has been suggested that this curious distribution is due to the passage of the spirochæte or its toxin along the perineural lymphatics drained by those peripheral areas in which "secondary" lesions are most common—e g, face chest, and perineum. For this migration, which presumably takes place in the acute stage without, however, necessarily producing root symptoms, no very satisfactory evidence is forthcoming, and the infrequency of any clinical manifestations of acute syphilis in those who later become tabetic is not in its favour. The explanation of this selective root involvement is, I think, still to seek, as in fact are the selective characteristics of most diseases. Another example of selective action in tabes is the well-established tendency for the fibres subserving pain to degenerate earlier than other afferent fibres, with the result that areas of analgesia are often the only sensory disturbances which can be demonstrated. Why this should be so it is impossible to say, unless it is in some unexplained manner concerned with the limited insulation of the peripheral nerve-endings of the fibres subserving pain as compared with the high degree of insulation enjoyed by the nervous system as a whole. The lightning pains of tabes are undoubtedly due to the implication of the pain fibres in the posterior roots, and pains indistinguishable from tabetic pains may occur as a consequence of the involvement of the posterior roots in a subacute meningitis. But although a meningitis may complicate tabes, it does not, according to most authorities, form an essential part of its pathology.

Primary or tabetic optic atrophy can no longer be regarded as a systemic degeneration; the changes in the optic nerves involve the interstitial tissues primarily and the nerve-fibres secondarily. Moreover, as Léri and others have pointed out, the retinal cells, the axons of which are represented by the optic nerve-fibres, remain intact, and contrary to what is often stated, the condition does not always go on to complete blindness.

LATENCY.

The latency of "parasyphilitic" affections is not confined to the nervous system, since many other syphilitic lesions, such as those involving the bones, are similarly delayed. Nevertheless, the latency of the nervous lesions is perhaps more consistent and pronounced than those of any other system. In general paralysis of the insane the average in 400 cases was 17 years from the date of infection; in tabes it is probably about the same or even longer. It is possible that the latency is in some way related to a phenomenon which has long been recognised—viz., the absence, or, at any rate, the insignificance, of "secondary" manifestations, as well as the relative rarity of gummatous lesions in tabetics and paralytics. Some curious views have emerged from a recognition of this singular coincidence. For example, general paralysis of the insane is about five times commoner in men than in women, and so uncertain was the diagnosis of chancre in the female sex before the discovery of the spirochæte and the Wassermann reaction, that our forefathers were in the habit of withholding treatment until the appearance, or otherwise, of a rash settled the matter. It has been suggested that the rarity of general paralysis of the insane in women is due to the fact that they were rarely treated in the primary stage. A precisely similar line of argument is responsible for the view that artificial—i.e., therapeutic—"suppression" of acute syphilis, particularly by the use of arsenical preparations, predisposes to tabes and general paralysis of the insane, or to put it more bluntly, "if you have syphilis at all, have it badly." But it must not be forgotten that in an enormous majority of cases of tabes and general paralysis of the insane the absence of secondaries is not due to treatment, since no treatment, or only very inadequate treatment, has been received. It is, therefore, not the suppression of the rash, but rather its failure to appear which is significant. Its non-appearance must be ascribed to some individual peculiarity, either of the virus or of the patient. Now, unless we accept the conception of a neurotropic virus, which on many other grounds appears inadmissible, there is little or no evidence of variations in virulence of different strains of spirochæte, and we have to conclude that the problem concerns the soil rather than the seed. It is permissible, therefore, to regard the presence of acute secondary manifestations in the absence of treatment as a token of the production of antibodies of sufficient quality and quantity to afford a considerable measure of protection to the essential nervous elements against subsequent degeneration. Such a view in no way justifies the withholding of treatment in expectation of a rash, although it is admittedly difficult to adduce satisfactory evidence that early treatment with arsenic, mercury, or both, influences the incidence or latency of late neurosyphilis in any particular direction.

The latency of parenchymatous neurosyphilis seems to me difficult to account for on any hypothesis, but it is not peculiar to syphilis, for a somewhat similar state of affairs prevails in disseminated sclerosis and encephalitis lethargica. The opponents of the toxic theory invoke two factors to explain the phenomenon: (a) an increased susceptibility of the tissues concerned, which renders them unduly vulnerable to (b) an exacerbation of spirochætes. How and why this exacerbation occurs is obscure. As regards (a) it is recognised that the reaction of the organism to microbic invasion is of two kinds, cellular and humoral, and it is not unlikely that these two modes of reaction are not necessarily proportional to one another in time or degree. On this hypothesis, for example, it may be supposed that in the tabetic, who has never had any manifestations of acute syphilis and only a very insignificant chancre, the cellular reaction is subnormal, whereas the humoral reaction (antibody production) is considerable, with the result that large numbers of parasites are fixed and rendered innocuous in the secondary stage, although a few escape and remain locked up in the nervous parenchyma. In such an individual it is further natural to suppose that owing to the relative meagreness of the cellular reaction hyperal'ergie takes an abnormally long time to develop; accordingly, many years elapse before his nervous system is capable of reacting forcibly to any exacerbation of its imprisoned spirochætes. These considerations are supported by the fact that in "mild" syphilis gummata are later in appearing than in "bad" syphilis. In the latter the cellular reaction is proportionately more pronounced than the humoral; hyperallergie develops quickly and gummatous syphilides follow close on the secondary stage. A serious inadequacy of both types of reaction is represented by cases of acute cachectic syphilis, where the patient dies, so to speak, without a struggle. This last mode of response is particularly found in unsyphilised communities, but is rare among the races of Western Europe. There can, I think, be very little doubt that the Western European is becoming more and more resistant to syphilis, and that this increasing immunity lies behind many of the problems of syphilis. It is possible that the preponderance of the humoral reaction over the cellular is an expression of this immunity, and if this be true, we should expect to find a greater incidence of parenchymatous neurosyphilis in those communities longest exposed to syphilitic infection. Whether this is so or not, I do not know; the statistical evidence is very conflicting.

THE WASSERMANN REACTION AND RESISTANCE TO TREATMENT

The treatment of syphilis is nowadays so intimately bound up with variations in the Wassermann reaction, that it is impossible to discuss one without the other. As is well known, the test is based on the fact that an antigen in the presence of its own specific immune body reacts or combines with the latter in such a way that the combination so formed has the power of "fixing" any complement that may be present. If now to such a system a hæmolytic serum (immune body) and its specific antigen (sensitised red cells) be added, no hæmolysis occurs, since the complement necessary to "complete" the hæmolysis is not available, being fixed. If, however, the antigen and immune body are not strictly homologous, the complement will remain free to combine with the hæmolytic amboceptor-antigen complex, and complete hæmolysis will result It is further well known that in Wassermann's original technique the antigen employed was specific—i e, an extract of syphilitic liver—but it was soon found that non-specific—i e, non-syphilitic—antigens served the purpose equally well, and the antigen most commonly used in this country and America at the present time is an alcoholic extract of non-syphilitic heart muscle with the addition of cholesterin In other words, the antigen now employed is a solution of lipoids and not necessarily, at any rate, an antigen at all Clearly, then, the reaction is not biologically specific in the sense that the agglutination of typhoid bacilli by typhoid serum is specific, and we accordingly are not justified in regarding the Wassermann reaction, or the simpler precipitin tests of Sachs-Georgi and others, as true immunity reactions But in view of the great delicacy of the test as an indication, at least in non-tropical countries, of past or present syphilitic infection, it is evident that we are dealing with some substance which is almost invariably present in the blood as a consequence of such infection The question arises, What is the nature of the reacting substance (reagin) and where does it arise? Until these questions can be answered the significance of a positive Wassermann reaction, apart from diagnosis, must remain to some extent conjectural, and so far as I am able to form a judgment they still await an answer It is thought that this reagin may be a lipoid-protein compound produced by the tissue cells in contact with the parasite, and that this antibody-like substance, linked with serum protein, possesses a greater aptitude for flocculating organic lipoids in suspension than is possessed by the serum proteins of a healthy individual According to this view, reagin cannot be regarded as a true antibody in the sense that it is inimical to the spirochæte It might be interesting to compare the non-specific Wassermann reaction in all stages of syphilis with a reaction carried out with a specific antigen—e g, a culture of dead spirochætes

As to the diagnostic value of the reaction there can surely be only one opinion—namely, that in the hands of a competent serologist it constitutes one of the most delicate tests of its kind in the whole range of medicine As regards its significance in other directions, however, opinions vary Does, for example, a positive reaction indicate that the tissues *are reacting* to living spirochætes, or merely that they *have so reacted* in the past? Is, in other words, a positive reaction tantamount to a *persistence* of activity of the infective agent? So long as the reaction remains biologically unspecific *it is difficult* to see how these vital questions can be answered with any finality, and accordingly we shall continue to be witnesses of courses of treatment being meted out to positive Wassermann reactions, irrespective of any other evidence of the existence of syphilitic lesions In unwise hands the impetus given by the researches of Ehrlich and Wassermann is in danger, as Nonne has said, of degenerating into a frenzy, while its tendency to promote syphilophobia, a condition more intractable than syphilis itself, constitutes a real and increasing menace; a passion to treat syphilis does not always preclude neglect of the syphilitic But it is as well to remember that anyone who takes up the attitude that he intends to regard a positive reaction as evidence of spirochætal activity until it is proved to be otherwise, and, therefore, is bound to treat it, is perfectly justified in doing so provided that he does not lose sight of the fact that the mental reaction of his patient is at least as important as that of his serum

VIEWS CONCERNING TREATMENT.

Success in the treatment of such conditions as tabes and general paralysis of the insane is obviously limited in scope, we cannot expect to do more than check or at the most arrest the course of the disease There is no question of restoring the function of nerve-fibres or cells which have already undergone degeneration But even within these limits late parenchymatous neurosyphilis is resistant to treatment, as also are the associated changes in the cerebro-spinal fluid. Seeing that our ideas as to treatment must conform with our ideas of the nature of the condition to be treated, it is not surprising to find two extreme views in opposition The one, maintaining that these conditions represent a premature decay of nervous elements as a result of prolonged intoxication by the syphilitic virus, declaims on the utter futility of any treatment at all This view, now almost defunct, provides a sharp contrast with the other, which, insisting on the fundamental pathological unity of all syphilitic processes, advises with logical consistency antisyphilitic treatment for the rest of the patient's life When one inquires why the results of life-long treatment are not more encouraging, one is offered the choice of two explanations The first is that the essential nervous elements, whether frontal lobes or posterior roots, owing to certain anatomical arrangements or physiological peculiarities, cannot be reached by the remedies employed, and that treatment can only effect improvement to the extent that the lesions are mesoblastic and not parenchymatous The same line of argument maintains that positive Wassermann reactions which persist in spite of treatment are due to spirochætes locked away in inaccessible non-vascular fastnesses, such as the wall of the aorta The whole subject bristles with difficulties, and the alleged impenetrability of the brain to arsenic seems to require further investigation Moreover, evidence is accumulating that in general paralysis of the insane many spirochætes may be found in the perivascular sheaths or even within the lumen of the small vessels, in situations, that is to say, where theoretically they should be accessible The second plea put forward by those who favour life-long treatment is that the patient would be worse without it As regards general paralysis of the insane a defence of this kind is difficult to accept; possibly the use of tryparsamide may alter the position, but omitting from the argument a drug the effects of which, though promising, cannot yet be estimated, there is no convincing evidence that treatment with anti-syphilitic remedies has any consistent effect in checking or aborting the disease As least, the results since the discovery of 606 have not been sufficiently encouraging to obstruct the introduction of an entirely different form of therapy—viz, the non-specific With regard to tabes, the complicating factors are so numerous and the results correspondingly difficult to estimate that dogmatism should be impossible Unfortunately, it flourishes abundantly From being an enthusiastic advocate of energetic arsenical treatment as a means of aborting the tabetic process and allaying its more unpleasant symptoms, I have become more guarded in my views and not a little sceptical As regards the choice of drugs, I should now unhesitatingly vote for mercury, and it is surely no light matter to disregard the favourable opinion of mercury held by such experienced and prudent neurologists as Babinski and Nonne Any opinion, however, of the extent of our ability to arrest or abort the disease is valueless unless it is realised that tabes frequently comes to a halt, often at an early stage, in those who have been treated (*a*) adequately, (*b*) inadequately, and (*c*) not at all. The *doubt* arises as to what extent, if any, groups (*a*) and (*b*) belong to group (*c*) The point might be settled by withholding treatment from large numbers of tabetics, particularly in the early stages, an experiment which, at the moment, I should regard as scarcely justifiable in view of my belief that to an extent which is *appreciable*, but not capable of more precise definition, the disease can be arrested or aborted by treatment with mercury

Alterations in the blood and cerebro-spinal *fluid* Wassermann reactions are by many regarded as an index to the efficacy of treatment As between general paralysis of the insane and tabes the position is somewhat different In the former both blood and cerebro-spinal fluid are strongly positive, are unaffected by specific treatment, and often remain positive during remissions In general paralysis of the insane the spirochætes are confined to the nervous system, and are only exceptionally found in the other body organs, hence the positive blood reaction may be presumed to be an "overflow" from the brain In tabes on the other hand, the reaction in the blood is positive in only 70 per cent. of the cases, and in approximately the same number in the fluid The blood reaction in tabes can be left out of discussion, as it may be due to visceral changes such as aortitis, wholly outside the nervous system Although many of the changes in the cerebro-spinal fluid in tabes (protein content, cells, colloidal gold curve) seem to be influenced by specific treatment the Wassermann reaction is highly but not completely resistant In many tabetics the fluid Wassermann reaction changes from positive to negative irrespective of treatment and once this has occurred it usually remains negative Unfortunately however many tabetics with negative fluids get rapidly worse in spite of treatment, and many with positive ones remain stationary, irrespective of treatment

For example, a patient of mine now aged 60 admits infection in 1894, he took mercury pills for a month and had no secondaries, his children, all under 20, are healthy, in 1909 Argyll Robertson pupils and absent knee- and ankle-jerks were accidentally discovered, at that time his blood was normal and his cerebro-spinal fluid abnormal (W R +), and he again took mercury pills for a month He has never had any further treatment In 1915 he came under my care with a gunshot wound in the thigh, in addition to the above signs he had some ulnar and lumbo-sacral analgesia, and his fluid was normal It was again normal in 1919, and to-day—i e, after 18 years—his condition is in statu quo and he has never had any symptoms of nervous disease

Lightning pains and the various crises of tabes are sometimes regarded as evidence of the activity of the process, and therefore a signal for energetic treatment This view is supported by the frequent exacerbations of the symptoms following injections of arsenical compounds On the other hand, whatever may be the explanation of these phenomena—and in my experience gastric crises are among the most resistant to treatment of all tabetic symptoms—it is difficult to regard them as evidence of an active pathological process, seeing that they may persist for years, although the disease in all other respects is quiescent and stationary The following case exemplifies this and also illustrates another curious feature of the disease—viz the beneficial effects on the course of tabes which may accrue from the development of a gummatous lesion

G K, aged 57, infected aged 23 treated with pills for a few months, no secondaries aged 36, he began to suffer from severe rectal crises which have persisted with varying intensity to the present time He was treated for fistula, fissure, dysentery, rectal bilharziasis (!) and was once threatened with an operation for carcinoma of the rectum Later he became impotent, had slight urinary incontinence, suffered from lightning pains in his legs, and rapidly lost flesh, he was then told he had phthisis

When examined, aged 49, he had Argyll Robertson pupils, absent tendon-jerks, profound sacral analgesia, and disturbance of postural sensation in feet No visceral disease W R ++ in blood, C S F W R +, globulin in excess, 18 cells per cubic millimetre He was given a course of 2 25 g of N A B intravenously, followed by mercury pills for three years, his pains diminished but the rectal crises continued, although controlled by morphia suppositories

Aged 50, blood W R —.

Aged 52, gummatous orchitis, W R blood ++, 2 5 g N A B, following which W R blood — No treatment since except morphia suppositories, without which the rectal crises are "as bad as ever"

Aged 54 to 57, cerebro-spinal fluid and blood examined twice, both negative He has put on weight and is better now in every way than he was 20 years ago, and the physical signs are unaltered

NON-SPECIFIC THERAPY

So unsatisfactory has been the response of late parenchymatous syphilis to the established methods of treatment, that we have been driven so to speak, to desperate remedies The first of these was intrathecal medication—i e, the introduction of salvarsanised sera or small doses of arsenical compounds directly into the subarachnoid space, either spinal or cerebral or both This method is now, we may hope, moribund for apart from its dangers, of which I have had several unhappy experiences, it is based on the false assumption that the cerebro-spinal fluid is a lymph bathing the nervous parenchyma The very opposite, however, is the case, since the fluid is probably a secretion of the choroid plexuses, possibly a dialysate, but certainly not a lymph and, moreover, in its relation to the brain and cord it represents the way out rather than the way in, an effluent rather than an affluent The second drastic step was the introduction of non-specific therapy, a method with which we are now becoming familiar in the shape of the malaria treatment of general paralysis The beneficial effects of intercurrent febrile disease in general paralysis of the insane have long been recognised, but no systematic attack was made along these lines until Wagner van Jauregg began inoculating paretics with Koch's tuberculin in 1887 The tuberculin was succeeded by typhoid vaccine, then by various proteins, and finally, in 1917, by the blood of patients infected with benign tertian malaria It may be too early yet to assess the true value of this method, but we must be careful not to prejudge it merely because it sounds fantastic and improbable. There can be little doubt that malaria treatment depends not on any specific effects of malarial infection as such, but rather on the general reaction of the organism to infection In fact, the choice of malaria seems to have been guided more by chance and convenience than anything else The whole question of therapeutic immunisation has recently been dealt with by McIntosh

"In therapeutic immunisation two factors are at work, a specific and a non-specific The specific is a typical antibody response, while the non-specific appears to be mainly dependent on a general stimulation of the tissues and leucocytes, in fact, to a process comparable to fever, in recent years there has been a greater tendency to make use of the valuable non-specific response"

According to a minority of investigators the results of malaria therapy in general paralysis of the insane are better if combined with antisyphilitic treatment on the assumption that the febrile process in some way "unlocks" the parasite and renders it accessible to the action of spirochæticides It is claimed for the method that remissions are more numerous and lasting, and are associated with disappearance of the parasite from the brain as confirmed by autopsy There appears to be no strict parallelism between the clinical improvement and the changes in the cerebro-spinal fluid Gerstmann has recorded 33 per cent of complete remissions out of 400 cases, many, it is true, in a very early stage of the disease, while of 209 cases treated in English institutions, nearly a quarter recovered sufficiently to permit of their being discharged According to a report by the London County Mental Hospital Service, complete remissions occurred in about one-third of the cases in a mixed series, but in a much greater proportion, if only those cases with histories of less than 18 months' standing were treated After making due allowance for the liability to long lasting remissions which may occur in untreated cases and also for the danger to life inseparable from the method it is difficult to avoid the conclusion that, *if figures mean anything*, we are no longer justified in withholding malarial therapy from any case in the earlier stages of general paresis

CONCLUSIONS

1 The introduction of salvarsan and its allied compounds in the treatment of syphilis, other than

in the Wassermann negative primary stage has not succeeded in protecting the human nervous system from syphilis, on the other hand there is no evidence that it has increased neurosyphilis

2 The influence of arsenical compounds in modifying the incidence, time of onset, and character of neurosyphilis remains to be determined

3 The pathological changes which occur in the nervous system including its coverings and in the cerebro-spinal fluid from the time of infection up to the development of late parenchymatous neurosyphilis and the mutual relations which exist between these changes are still largely a matter of conjecture

4 The value of antisyphilitic treatment in arresting the progress of tabes and allied conditions is difficult to estimate owing to their liability to undergo spontaneous arrest

5 The Wassermann reaction is not biologically specific, and its value as a guide to and indication for treatment cannot therefore, be regarded as absolute

6 The non-specific treatment of general paralysis has according to the published figures achieved better results than any previous method

7 A majority of the unsolved problems of syphilis are intimately bound up with the increasing immunity to syphilis of the civilised peoples, together with the lack of any method by which this immunity can be estimated

Goulstonian Lectures
ON
CARDIAC DYSPNŒA.

The Second Goulstonian Lecture in 1927, delivered before the Royal College of Physicians of London on March 15th

BY FRANCIS R FRASER, B A. CAMB, M.D, F R C P EDIN, F R C P LOND,
DIRECTOR OF THE MEDICAL PROFESSORIAL UNIT, ST BARTHOLOMEW'S HOSPITAL, PROFESSOR OF MEDICINE IN THE UNIVERSITY OF LONDON

LECTURE II *

CARBON DIOXIDE AND HYDROGEN-ION CONCENTRATION IN THE ARTERIAL BLOOD

THE volume of carbon dioxide in the arterial blood can be measured directly The method of Van Slyke (constant volume apparatus) has been used in this series The volume of the gas is not, however, an indication of the pressure of the gas, since at a given volume the pressure will depend on the quantity of alkali available for combination with the carbon dioxide and it is the pressure that is the effective stimulant to the respiratory centre There is no satisfactory method for the direct determination of the pressure of carbon dioxide in the arterial blood and indirect methods must be utilised By determining the volumes of carbon dioxide that can be taken up by the blood at different pressures of the gas at the temperature of the body and plotting the values so obtained a carbon dioxide dissociation curve [25] is constructed The pressure on this curve that corresponds to the volume of carbon dioxide in the arterial blood as actually determined should then be the pressure of the gas in the arterial blood This curve is usually constructed from observations made with venous blood and although venous blood may give a curve accurately representing the conditions in the arterial blood in normal healthy persons it does not necessarily do so in conditions of disease Morawitz and Walker [26] and Meakins, Dautrebande and Fetter,[27] have shown that venous blood has not the same carbon dioxide combining power as arterial blood in the presence of stasis This factor is likely to be present in cases of heart failure and Fraser, Graham, and Hilton [28] showed that the dissociation curves constructed with venous and with arterial blood in cases of heart failure are not identical To obviate this fallacy the dissociation curves in this series of observations have been constructed with arterial blood It is obvious that the greater the number of points used in constructing the curve the more accurate will the curve be, and whenever possible four points have been used This requires a considerable amount of arterial blood The method of radial puncture introduced by Hurter,[25] was found to be not sufficiently reliable for obtaining the necessary amount of blood and so puncture of the femoral artery [29] has been introduced and utilised throughout these observations By this method 50 c cm of arterial blood is easily obtained The blood is oxalated and sodium fluoride is added as suggested by Lovatt Evans [30] to prevent glycolysis Even when thus constructed, the dissociation curve cannot be relied upon to give accurate values for the arterial carbon dioxide pressure partly because four points are not sufficient if any one of them happens to lie a little off the curve of the other three, and partly because the changes undergone in blood from cases of diseased states when drawn and reheated in tonometers has not been sufficiently investigated A second and additional method has therefore been employed in most of the cases The pH of the arterial blood and of the samples of blood from the tonometers has been determined directly by the Hastings-Sendroy [31] colorimetric method In this way the pH of the blood at different carbon dioxide pressures has been determined The pH-carbon-dioxide-pressure curve has been constructed from them and the pressure corresponding to the pH of the arterial blood found from the curve Any alteration in the acid-base relationship of the blood after withdrawal from the body would result in changes in opposite directions in the values of the arterial carbon dioxide pressure obtained by the two methods Thus if the blood became more acid after withdrawal, the value obtained by the dissociation curve would be too high and that by the pH-pressure curve too low It is probable that the figure obtained from the dissociation curve is the more accurate since the carbon dioxide volume can be determined with much greater accuracy than can the pH by the methods employed. By considering the figures so obtained an approximate value for the arterial carbon dioxide pressure is arrived at, and the figure obtained from the dissociation curve has been regarded as the more reliable of the two When there has been a pronounced discrepancy between the figures obtained by the two methods the results have been discarded

CASES WITH MITRAL STENOSIS AND AURICULAR FIBRILLATION.

The results in the group of cases with mitral stenosis and auricular fibrillation are shown in Table V. In accordance with the practice of other observers, the amount of alkali available for combination with carbon dioxide, or the level of the dissociation curve, has been indicated by giving the carbon dioxide capacity of the blood at a pressure of 40 mm. of Hg. This figure is obtained from the dissociation curve, and will be accurate only in so far as the curve can represent truly the condition of the arterial blood.

---

* Lecture I appeared in THE LANCET last week

TABLE V.

Carbon dioxide content and pressure, and hydrogen-ion concentration of arterial blood in same cases as in Table II.

Case No.	Date	Dyspnœa	Arterial blood					
			CO_2 content	CO_2 capacity at 40 mm Hg	CO_2 pressure		pH	
					From dissociation curve	From pH pressure curve	Colorimetric	Calculated
			V%	V%	mm	mm		
1	15/12/24	+	42·2	44	36	30	7·48	7·36
2	22/12/24	+ +	42·9	46	31	26	7·47	7·43
	12/ 1/25	–	55·6	59	33	31	7·33	7·52

8	16/ 6/24	+	40·8	42	39	–	–	7·32

V% = Volumes per cent

In health the limits of variation of the arterial carbon dioxide volume are wide. Harrop[16] found figures ranging from 44·6 to 52·9 volumes per cent. in ten healthy individuals. The amount of alkali available for combination with carbon dioxide as indicated by the carbon dioxide content at 40 mm. of Hg pressure, also varies greatly, and Peters, Barr, and Rule[32] conclude from their own observations and those of others that variations from 43·3 to 55·9 volumes per cent. with an average of 49·3 may occur in healthy subjects, though it is more constant than this in any one individual. The variations in arterial carbon dioxide pressure in health have been arrived at mainly by determination of the pressure in the alveolar air, which in health is almost identical with that of the arterial blood. Figures varying from 35·0 to 40·8 mm. of Hg have been published,[32] but this method of determination is not available in diseased conditions and in cases of dyspnœa. Figures obtained from carbon dioxide dissociation curves have been published and show wider variations than these, but the dissociation curves were constructed from observations on venous blood. It is obvious, then, that much caution must be used in concluding that the figures for arterial carbon dioxide volume and pressure and capacity are indicative of significant departures from the normal in any single observation. Changes from one observation to another in the same individual under resting conditions will, however, be of greater significance.

The figures for the carbon dioxide content, as shown in Table V., are in general about the lower limit of the normal with certain obvious exceptions. In Case 3 the figures are clearly below normal limits on the first and fourth observations when the dyspnœa was particularly severe. In Case 2, while the figure obtained when the dyspnœa was present is at the lower limit of the normal, it is above the upper limit on the second observation when no dyspnœa was present. The one observation on Case 6 gives a figure near the upper limit of the normal at a time when the patient had greatly improved and only slight dyspnœa was present. Both observations on Case 5 gave values distinctly above the normal limits, and this is the case with low figures for oxygen saturation. In Cases 2, 3, and 4, in which two or more observations were made, it is seen that the figure is in each instance lower at the time of greater respiratory distress.

The values for the carbon dioxide capacity of the blood, as indicated by the volume at 40 mm. pressure, fall in general within the normal limits. Cases 7 and 8, and the third observation in Case 4, gave figures that are lower than the accepted normal or about the lower limit of the normal. At the second observation in Case 2 the capacity was definitely above the normal range, and in Case 5 the capacity was a high normal on both occasions.

The carbon dioxide pressures by either method are lower than the accepted normal values in Cases 2, 3, and 4, are within normal limits in Cases 1 and 8, and above the normal in Cases 5, 6, and 7. Cases 2, 3, and 4 are examples of severe cardiac dyspnœa uncomplicated by primary lung disease and in young subjects, so that the complications of arterial disease, renal insufficiency, emphysema, &c., are not likely to be present. In Cases 1 and 6 the dyspnœa was slight, and the patients had recovered considerably from the attacks of heart failure when the observations were made. Case 5 had evidence of pulmonary complications, and inefficient gaseous exchange in the lungs was demonstrated by the oxygen unsaturation of the arterial blood. In Cases 7 and 8 the patients are much older than the others of this group. In Cases 2, 3, and 4 several observations were made in states of severe dyspnœa and more pronounced failure, and in states of partial recovery. In Case 3 the second observation was made during recovery from the condition present at the time of the first observation, and the third during a slight relapse from overdosage with digitalis. The fourth observation was made during a subsequent admission to hospital because of a severe recurrence of the heart failure, and the fifth observation during partial recovery from this. The carbon dioxide pressures are lowest when the dyspnœa is most severe, and in each case the values rise towards or to normal in the recovery stage. In the two observations on Case 2 the pressure is higher in the recovered state. In Case 4 there are three observations. At the time of the first the dyspnœa and failure were severe, at the time of the second there was considerable recovery and the pressure is slightly higher. The third observation was made during a later admission to hospital when the patient's condition was much worse. The dyspnœa was severe and, notwithstanding this, the carbon dioxide pressure is within normal limits, suggesting that there was some impairment of the carbon dioxide exchange in the lungs. This patient died shortly after the observation was made, and the conditions were, therefore, not comparable to those present at the time of the earlier observations. If this one observation be omitted, the results in these three cases (2, 3, and 4) point to an association of a low arterial carbon dioxide content and pressure with severe dyspnœa, and to a lessening in the severity of the dyspnœa being accompanied by a rise in the carbon dioxide volume and of the carbon dioxide pressure. The carbon dioxide capacity of the arterial blood, although never below the limits of the normal, shows a similar if small rise with the rise of pressure and of volume that occur with recovery. The second observation on Case 2 shows a high figure for carbon dioxide capacity and a pronounced rise on recovery. The reason for this exceptionally high figure and the exceptional rise is not obvious. In the other observations on these cases the results are such as might be expected as a consequence of a low carbon dioxide pressure in the alveolar air from increased ventilation. Such a low alveolar pressure would result in a low arterial pressure and a low volume, and a readjustment of base would then take place, as Henderson and Haggard[13] have shown, with a lowering of the amount of base available for combination with carbon dioxide—that is, a lowering of the carbon dioxide capacity. If a similar mechanism is present in the other cases also some other factor must be present to account for the different results in them.

In Case 5 the arterial carbon dioxide pressures are above the normal range, in spite of the severe dyspnœa and respiratory efforts. This points, in the absence of any signs of obstruction to the air passages, to a faulty exchange between the gases of the alveolar spaces and the blood or to insufficient ventilation of the alveolar spaces. Such an explanation is supported by the low oxygen saturation in the arterial blood. It will be noted that the carbon dioxide capacity is also high, as a result of the expected readjustment of base. In Case 6, in which the dyspnœa was but slight, a high carbon dioxide pressure is present, but the oxygen saturation is good. This could only be accounted for if there could be a degree of faulty exchange or ventilation sufficient to effect the efficient exchange of carbon dioxide, but not sufficient to affect the saturation of the blood with oxygen. That such a situation can arise is supported by the experimental work of Blalock, Harrison, and Wilson,[33] who found that in healthy lungs obstruction to ventilation may result in a rise of the carbon dioxide in the arterial blood *before anoxæmia, as indicated* by the oxygen saturation, is produced. As they point out, this is contrary to the conclusions of Hastings, Neill, Morgan, and Binger,[34] who based their findings on work on pneumonia. The same situation is present in Case 7, but in this case the dyspnœa was severe, the respiratory effort apparently keeping the ventilation sufficient to prevent anoxæmia, but not to maintain an efficient carbon dioxide exchange. In Cases 1 and 8, and on the third observation in Case 4, the carbon dioxide pressures are at high normal levels in spite of the pronounced respiratory efforts, and the same explanation will account for the difference between the results in them and in Cases 2 and 3, and the earlier observations in Case 4, in which the exaggerated respiratory efforts were accompanied by low arterial *carbon dioxide pressures*. The method of estimating the oxygen in the blood in terms of saturation is not entirely satisfactory. The pressure of the gas is the essential factor, and it is possible that the apparent discrepancies between oxygen and carbon dioxide exchanges would disappear if oxygen pressures were estimated throughout.

While Cases 5 and 6 illustrate the raised carbon dioxide capacities in the presence of high arterial carbon dioxide pressures, Case 7 had the lowest capacity in the series in spite of a pressure above the normal limits. This patient was aged 59, his arteries were thickened, and there were numerous granular casts in the urine, and the low capacity may be accounted for by an *inability to readjust* base owing to renal and other changes accompanying age and arterio-sclerosis. A similar inefficiency of readjustment, though less in degree, is seen in Case 8, aged 67, and in the third observation in Case 4 shortly before the patient died.

In this group of cases, therefore, we find that in the study of individual cases lower carbon dioxide pressures are found in arterial blood the more severe the dyspnœa, but that in some cases severe dyspnœa is accompanied by high pressures. It is *clear*, therefore, that this type of dyspnœa cannot in general be due to high carbon dioxide pressure in the blood supplied to the centre. The results are understandable however if there is some factor other than low arterial oxygen saturation or high arterial carbon dioxide pressure stimulating the *centre to cause* hyperpnœa. This hyperpnœa would then result in low arterial carbon dioxide pressures in the cases with free pulmonary ventilation and efficient gaseous exchange between alveolar air and blood but might not be sufficient to lower the carbon dioxide pressure or to prevent a raised pressure in those cases *in which* pulmonary ventilation is obstructed or gaseous exchange with the blood inefficient. The congestion of the lungs and the œdema consequent on the heart failure are obvious possible causes for hampered ventilation and inefficient gaseous exchange.

Because of the retention of fixed acids, a raised hydrogen-ion concentration in the blood supplied to the centre is present in diabetic coma and in uræmia, and it is probably the cause of the hyperpnœa seen in these conditions.[35] In uræmia we have found low arterial carbon dioxide pressure, content, and capacity associated with normal oxygen saturation. The determination of the hydrogen-ion concentration of the arterial blood in cardiac dyspnœa is, therefore, of importance, since in it we find low carbon dioxide values and normal oxygen saturation. For convenience the logarithmic *expression—the pH of* Sörensen—has been utilised, and this has been determined for the whole blood in two ways. It has been calculated from the carbon dioxide volumes and pressures by the Hasselbalch formula according to the method of Van Slyke, Hastings, Murray, and Sendroy,[36] and it has been determined directly by the colorimetric method of *Hastings and Sendroy*.[31] The calculated values depend for their accuracy on the accuracy of the carbon dioxide dissociation curves, and will fail to represent the true arterial conditions in so far as these curves fail to do so. The direct determinations by the colorimetric method agree very closely in conditions of health with the values obtained by the *hydrogen electrode, but* considerable discrepancies have been reported in diseased conditions, and until the causes of these discrepancies are understood the calculated values are more reliable, although the colorimetric readings have the advantage of being independent of the determination of carbon dioxide contents or dissociation curves by means of which *the calculated* values are obtained. It is difficult to place the limits of the normal variations in arterial pH, and Austin[37] gives them as 7·30–7·50, though the variations in any one individual are almost certainly less than this. A study of the figures in Table V. shows that with only two exceptions the values all fall within these normal limits. The calculated pH on the *second* observation in Case 2, when the carbon dioxide capacity rose to an exceptional degree, is 7·52, which is more alkaline than the normal variations permit, but the colorimetric determination in the arterial blood is 7·33. In Case 7 the calculated value is 7·26, which is outside the limits on the acid side. Although the other values lie within the accepted limits, they are near the alkaline limits at the time of severe dyspnœa in Cases 2, 3, and 4, and are less alkaline in general on *improvement*. The values are near the acid limits in Cases 6 and 8. In Cases 6 and 8 the unusually high carbon dioxide pressures in the arterial *blood* are just compensated by the *readjustment* of base to avoid abnormal hydrogen-ion concentrations, but in Case 7, with pronounced arterio-sclerosis and renal changes, this compensation has failed. It is of importance to note that in Case 5 the carbon dioxide pressures are the highest in this group of cases, but high carbon dioxide capacity keeps the pH easily within normal limits. In Cases 1, 2, 3, and 4, with low carbon dioxide pressures, compensation by readjustment *of base and lowering* of carbon dioxide capacity is successful in keeping the pH within the limits of the normal on the alkaline side. This group of cases, therefore, shows that so far from severe cardiac dyspnœa being accompanied by increased hydrogen-ion concentration in the arterial blood, normal values are the rule, and there may be a lowering of the hydrogen-ion concentration *to the alkaline* limits of the normal with a rise later as the severity of the dyspnœa diminishes.

CASES WITH HIGH BLOOD PRESSURE AND ARTERIAL DISEASE.

The results of the *observations* on the carbon dioxide and hydrogen-ion concentration in the second group of cases are recorded in Table VI. This group consists of the six patients who had dyspnœa and heart failure with high blood pressure and arterial disease but no evidence of endocarditis. The volume of carbon dioxide *in the arterial* blood is below the limits of the normal variation in four (10, 11, 12, and

14) of the six cases, and about the lower limit in Case 9 The second observation on Case 13 is the only figure well inside the normal limits, and this is the case in this group that showed the low oxygen saturation of 87 8 per cent. (see Table II) In the second observation on Case 10 the volume of carbon dioxide is only 27·6 per cent, the lowest in the whole series, but this observation was made a few hours before the death of the patient The carbon dioxide capacity is, in general, within the accepted limits of the normal, except at the second observation on Case 10 just before the death of the patient, and at the first observation on Case 13, when the failure was extreme In these instances the figures are too low, presumably from faulty elimination of fixed acids In Case 13 the capacity rose as the general condition of the patient improved, As in the group of cases with mitral stenosis, the carbon dioxide pressures in the arterial blood are generally below the normal values Case 13 is the one exception, for at the two earlier observations the pressures are markedly high, and at the third, when the patient was greatly improved, the pressure had come down to a normal value The low oxygen saturation (see Table II) and high carbon dioxide pressures in this case are exceptional, and point to an inefficient gaseous exchange from œdema of lung tissue This prevents the effect of the hyperpnœa on the arterial blood which is observable in the other cases The hyperpnœa in the other cases must be the result of some respiratory stimulus other than low saturation or high carbon dioxide pressure in the arterial blood, and it causes in this group of cases, as in the group with mitral stenosis a washing out of carbon dioxide from the lungs with low figures for arterial carbon dioxide pressure, capacity, and volume That the respiratory stimulus is not increased hydrogen-ion concentration is seen on examining the figures for the pH in Table VI, for they fall within the normal limits with three exceptions On the second observation on Case 10, shortly before the patient's death, the calculated pH is too acid, and on the first observation in Case 13, when the failure was extreme and the arterial carbon dioxide pressure high, the value is outside the normal to the acid side, and with recovery more alkaline values were obtained In Case 11 the calculated pH is outside the normal range on the alkaline side In Cases 9 and 12 the hydrogen-ion concentrations are in the alkaline half of the normal range In this group, therefore, as in the group of mitral stenosis cases, there is no indication of retention of acid bodies as the cause of the dyspnœa except in the patient with extreme failure and faulty exchange of gases in the lungs, and in the observation of Case 10 a few hours before the death of the patient

CASES WITH PULMONARY DISEASE IN ADDITION TO HEART FAILURE.

The results in the three cases with pulmonary disease and the two unclassified cases are shown in Table VII The volumes of carbon dioxide in the arterial blood are all high, either around the upper limit of the normal or definitely above as in Case 17, and the first observation in Case 15 The carbon dioxide capacities are higher than in the other groups, and in Case 17 it is definitely above the limits of normal variation The carbon dioxide pressures are around the upper limit of the normal in Cases 18 and 19, and markedly above the normal in all the other observations, with the exception of the second observation on Case 15 In Case 17 and in the third observation on Case 15 the pressures could not be determined with any accuracy, as the arterial point lay beyond the ascertained range of the dissociation curve, and could only be arrived at by extrapolation That the pressures were abnormally high is, however, undoubted At the second observation on Case 15, when the figures for the pressure were below the normal range, the patient's condition was greatly improved, and he was quite free from signs of bronchial spasm which were present at the other observations, though orthopnœa and signs of heart failure were still evident This group is characterised, then by high carbon dioxide pressure in the arterial blood, with normal or high capacity and high carbon dioxide volumes This high carbon dioxide pressure in the presence of dyspnœa is accountable on the pulmonary lesions present in Cases 15, 16, and 17 In Case 18 it may be due to the holding of the breath that was noticeable in the presence of the paroxysms of pain of angina pectoris In Case 19 the general feebleness of the patient with carcinoma of the uterus might conceivably account for it The low pressure at the second observation in Case 15 would appear to indicate that in the absence of the bronchial spasm this case is essentially the same in the mechanism of the dyspnœa as the cases in the other groups, and it is probable that in so far as the cardiac dyspnœa is concerned there is a mechanism common to all the cases, though the evidence of it may be obscured in some by such complicating factors as pulmonary disease

TABLE VII

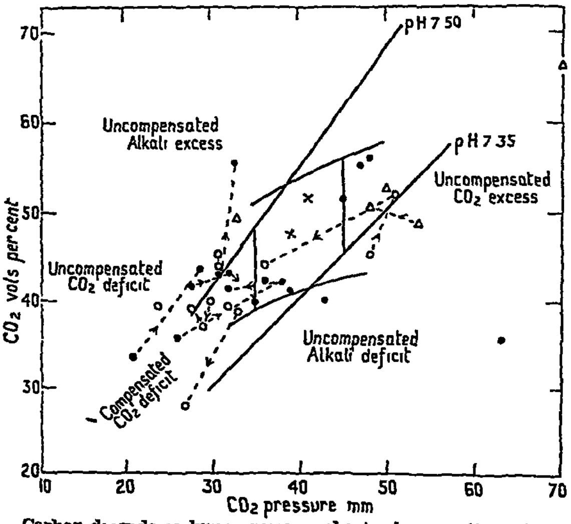
* Figures uncertain since that for CO_2 pressure was obtained by extrapolation

In view of the high carbon dioxide pressure it is not surprising to find hydrogen-ion concentrations as indicated by the calculated pH, that are abnormally high in Cases 15, 16, and 17 In Cases 18 and 19 values in the acid half of the normal range were found, and at the second observation on Case 15 a concentration towards the alkaline limit of the normal It is seen that in this group the colorimetric pH values differ considerably from the calculated and all lie within the normal range It is not possible to say which are the more accurate, in view of the profound disturbance of the acid base balance that is present, but the calculated values cannot be so accurate in these cases as in the others, because of the extreme position of the arterial points in the dissociation curves In the presence of the high carbon dioxide volumes and pressures in the arterial blood, the existence of a gaseous acidosis can be accepted



Carbon dioxide volume-pressure chart, showing the arterial points in Cases 1–19 The continuous lines enclose the normal area

● Cases 1–8 ○ Cases 9–14 △ Cases 15–17 × Cases 18 and 19

The arterial points for the 19 cases of the three groups have been placed on a carbon dioxide volume-pressure chart The area of normality, adapted from the chart of Hastings, Neill, Morgan, and Binger,[34] is shown, and it is seen that most of the arterial points are grouped in the areas representing compensated and uncompensated carbon dioxide deficit The points from the cases with pulmonary disease in addition to heart failure and from Case 13 lie towards or in the area of uncompensated carbon dioxide excess, those from Case 7 and the second observation in Case 10 are in the area of uncompensated alkali deficit, and that from the second observation on Case 2 in the area of uncompensated alkali excess The chart shows well that unless other factors are present in addition to heart failure, and so long as pulmonary congestion is not extreme, cardiac dyspnœa is accompanied by a condition in the arterial blood indicative of compensated or uncompensated carbon dioxide deficit, which is presumably the result of increased pulmonary ventilation

CONCLUSIONS ON CARBON DIOXIDE AND HYDROGEN-ION CONCENTRATION IN ARTERIAL BLOOD

The study of arterial blood in these 19 cases of cardiac dyspnœa permits of the conclusions that (*a*) in cases of extreme congestive failure and of pulmonary disease in addition to heart failure, faulty elimination of carbon dioxide and faulty absorption of oxygen in the lungs may be factors in the production of increased respiratory activity, and (*b*) in cases near death, retention of fixed acids, and raised hydrogen-ion concentration may be factors in the production of increased respiratory activity, but that (*c*) in cases of cardiac dyspnœa other than these the condition of the arterial blood cannot account for the dyspnœa, and is, indeed indicative of the presence of increased pulmonary ventilation to which the changes in the arterial blood are secondary. Since the changes in the arterial blood due to the conditions (*a*) and (*b*) would mask the effect of such increased ventilation, it is reasonable to suppose that there is a cause of increased respiratory activity present in all cases of heart failure, which is independent of the quality of the blood supplied to the respiratory centre

THE CHLORIDES OF GASTRIC CONTENTS

IN RELATION TO FREE ACIDITY

BY SINCLAIR MILLER, M D BELF,
AND
F B SMITH, M D CAMB,
HONORARY PATHOLOGISTS, ROYAL BATH HOSPITAL AND HARROGATE INFIRMARY

SINCE the publication by Ryle in 1920[6] the fractional method of gastric analysis as described by Rehfus and Hawk has found wide application in clinical work in this country, and much information is now available about the range of variation of gastric acidity in health and disease

Although it has long been accepted that the total *chloride content is the more accurate* index of the secretory activity of the stomach, records of such estimations by the fractional technique are relatively few, the most important being those of Bolton and Goodhart[3] These writers based their observations on 70 cases, and accepted the opinion of Boldyreff that the balance of muscle tone between the stomach and the pylorus is a most important factor in defining the degree of gastric acidity One of the results of the action of the pyloric sphincter is the control of the regurgitation of alkaline fluids to the stomach from the duodenum Bolton and Goodhart confirm the view that the total chlorides are a more accurate index of secretory activity and that the inorganic chlorides are a fair index of the degree of access of alkali to the stomach, mainly from the duodenum In 1924 Baird, Campbell, and Hern[1] published results of chloride estimations in fractional samples, and, on the evidence of simultaneous withdrawal of duodenal and gastric contents after test-meals, conclude that production of alkaline secretions by the stomach itself is at least as important a factor in control of gastric acidity as regurgitation of pancreatic and duodenal contents These writers also describe a method by which the estimation and calculation of the chlorides become practicable for routine clinical work

Our routine has been to estimate the chlorides in all fractional gastric analyses This communication is a survey of such estimations in 22 cases of Addison's anæmia and in 292 unselected cases of other diseases The technique for the test-meal is that outlined by Ryle[6] In approximately half of the cases examined by us the chlorides have been estimated by the complete Volhard method by fusion with and without alkali, and in the other half by the shorter and simpler method described by Baird, Campbell, and Hern the accuracy of which for clinical purposes we have confirmed Defining a unit of free acidity against Topfer's reagent or of chlorides as the equivalent of 1 c cm of N/10 HCl per 100 c cm of gastric contents, we have grouped our cases as follows —

1 Achlorhydria Free HCl absent in the resting stomach and throughout the test.
2 Hypoacidity Free HCl not greater than 10 units at any time after the administration of the meal
3 Normal acidity Free HCl greater than 10 units but not greater than 50 units after the meal
4 Hyperacidity · Free HCl greater than 50 units at some time after the meal

The following table shows the incidence of these groups of free acidity within the series, as well as the number of estimations of chlorides carried out at the various intervals of time in the course of digestion and passage of the meal.

The chlorides of the meal itself have been estimated repeatedly and found to vary from zero to 5 units, a negligible quantity in the interpretation of results Saliva expectorated during the test has been examined in 25 cases, in no case was free HCl present The total acidity to phenolphthalein varied from 0 to 10 units, the average being 5 units and the total chlorides from 10 to 55 units, the average being 20 units Allowance must therefore be made in considering the total chlorides of the fasting contents of the *stomach, which naturally may include an* appreciable amount of saliva This also emphasises the importance of taking precautions to exclude the swallowing of saliva after administration of a test-meal if the chlorides are to be estimated.

A = Achlorhydria (Addison's anæmia) B = Achlorhydria (other diseases) C = Hypoacidity D = Normal acidity E = Hyperacidity

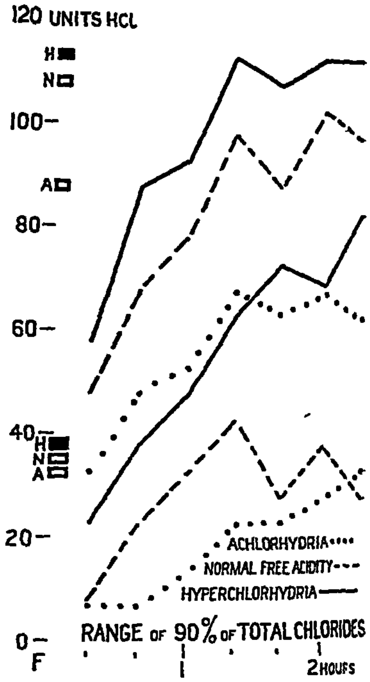
—	No of cases	Number of analyses									
		Hours after meal									
		0	⅓	⅔	1	1⅓	1⅔	2	2⅓	2⅔	3
A	22	16	18	16	7	7	5	4	2	2	
B	56	42	38	25	29	18	22	7	10		4
C	19	10	11	8	9	6	4	5	3		
D	181	113	113	70	107	62	72	39	26	11	9
E	36	21	23	12	23	9	17	4	6		
Total	314	202	203	131	175	102	120	59	47	13	13

The results of the estimations of chlorides indicated in the above table are expressed in two schemes of diagrams *(1) mean curves, representing the average figures at stated periods of time of digestion* (Figs 1 and 2), (2) curves defining the limits of 90 per cent. of the results (Figs 3 and 4) There is obvious general conformity in the shape of the average curves of total chlorides in all groups The total chlorides tend to return to the level of the resting contents of the stomach

The height of the curve of total chlorides places the various groups in an order of magnitude corresponding with the degree of free acidity (Fig 1) The appreciably high level of the total chloride curve in Addison's anæmia and other cases of achlorhydria shows that even in this group the secretion of HCl is appreciable but neutralised by alkali This fact is also demonstrated in Fig. 3 where the range of total chlorides in achlorhydria of other diseases than Addison's anæmia is seen to fall mainly within that for the group of normal free acidity, and even includes a portion of the zone covered by cases of hyperacidity The average curves and the range of 90 per cent *of the inorganic* chlorides in the various groups of acidity show only slight divergence, evidence that the absence of free HCl is most often due to access to the stomach of alkaline secretions, neutralising what may be potentially an appreciable degree of free acidity.

In all groups excepting that of hyperacidity the average curves of inorganic chlorides are broadly similar in shape to those of total chlorides, though at a lower level (Figs. 1 and 2), there is in both total and inorganic chlorides a rise in the curve within 40 minutes of taking the meal, and a tendency to return to the level of the fasting contents The former feature suggests that some secretion of alkali by the stomach is excited in almost immediate response to the meal Bennett and Dodds[2] demonstrated a correspondence between the curves of free acidity in the stomach and those of the pressure of CO_2 in alveolar air, and their published records provide some evidence that some output of alkali from the circulation commences about the same time as the arrival of food in the stomach In the case of hyperacidity the curve of inorganic chlorides remains almost horizontal at a distinctly low level up to two hours; there is a tendency to rise after two hours, but to a level appreciably less than in other groups This fact suggests that the secretion of alkali by the

FIG 3



AVERAGE CHLORIDES

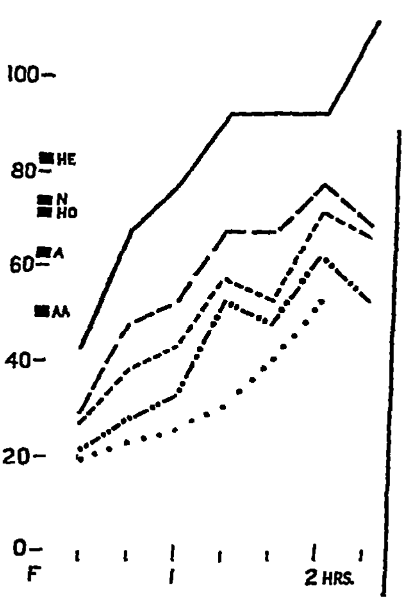


FIG 1.
Total chlorides

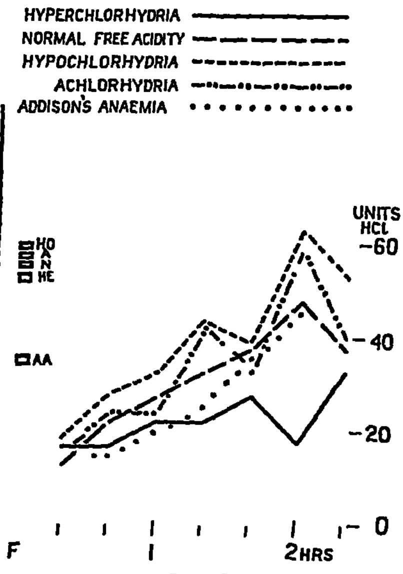

FIG 2.
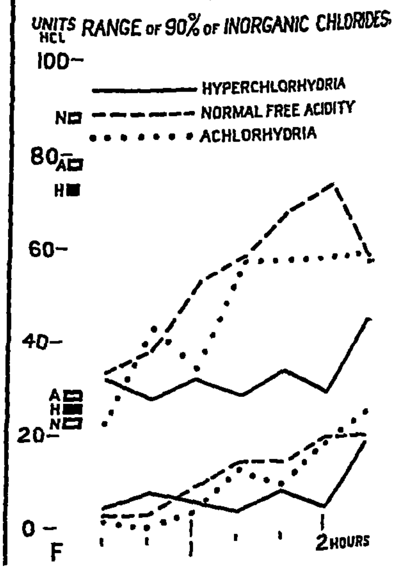
Inorganic chlorides

FIG 4



stomach is markedly deficient or delayed in this group.

Figs. 1 and 2 show clearly the association between deficient alkaline secretions and hyperacidity. The same point is brought out in Figs. 3 and 4, where a considerable proportion of cases with a normal range of free acidity are seen to have a range of total chlorides as high as many cases of hyperacidity, whereas the inorganic chlorides in cases of normal acidity are very much higher than those of hyperacidity.

The total and inorganic chlorides of the fasting contents of the stomach have a remarkably constant average in all groups of free acidity, the widest divergence being found in Addison's anæmia. In Addison's anæmia it is interesting to note the similarity of the shape of the average curve of the chlorides to that of other groups, the difference being only that of reduction in magnitude. The range of variation of the total chloride curves in Addison's anæmia falls within the zone of the curves of 90 per cent. of the cases of achlorhydria in other diseases. On the *basis of the figures for the total chlorides* there is no indication of any possible definition of so-called achylia as distinct from achlorhydria. The feature of the results of fractional test-meals in cases of Addison's anæmia is the rapid disappearance of *starch from the stomach.* In 16 (66 per cent.) of the 24 test-meals in cases of Addison's anæmia starch had disappeared from the fractional samples in one hour. In the cases of achlorhydria other than Addison's anæmia the proportion empty in one hour is 35 per cent. In the few fractional samples available in cases of Addison's anæmia after one hour the chlorides tend to rise, but at a slightly lower level than other cases of achlorhydria, an indication that a certain amount of HCl is secreted, but neutralised by alkali and absorbed by protein.

Summary.

1. The mean curves of total chlorides in all grades of gastric acidity are similar in shape, differing only in magnitude. 2. The mean curves of the inorganic chlorides have the same general form and relation to time of digestion as those of the total chlorides, but agree much more closely in magnitude. In hyperchlorhydria the inorganic chlorides tend to remain low or rise only very *slightly.* 3. On the basis of the figures of the chlorides there seems to be no clear definition of the so-called achylia of Addison's anæmia, as distinct from other cases of achlorhydria.

We wish to express our thanks to the honorary physicians of the Royal Bath Hospital for the use of their notes and permission to examine the cases: also to S. Linfoot for his technical assistance.

BRIGHTON AND HOVE PROVIDENT DENTAL HOSPITAL.—At the annual meeting on Feb. 25th it was decided to convert the hospital into a corporate body by registering it as a company with limited liability without the addition of the word "limited" to its name. The decision was unanimous, and the licence of the Board of Trade is to be sought. It was explained that the hospital had now a fairly large amount of invested funds which were in the hands of trustees, but it was felt that an institution of that kind should be master of its own funds and that it should be an incorporated body, having a definite legal status not dependent on cumbersome and obsolete trusts, and protecting its members from financial liabilities beyond those laid down. The annual report showed a decrease of 435 patients during the year; this was explained as due to the fact that the State, through the approved societies, was now providing dental benefit, formerly only available through charity.

POST-PARTUM AVULSION OF THE UTERUS:

A CASE OF RECOVERY.

BY R. H. BOGGON, M.B., B.S.LOND.,
SURGICAL REGISTRAR; FORMERLY SENIOR OBSTETRIC HOUSE PHYSICIAN, ST. THOMAS'S HOSPITAL.

With Remarks by

JOHN S. FAIRBAIRN, B.M. OXF., F.R.C.P., LOND., F.R.C.S. ENG.,
OBSTETRIC PHYSICIAN TO ST. THOMAS'S HOSPITAL.

THE following case is of interest as it reveals how completely a woman may recover from the effects of so serious a disaster as the tearing out of the whole uterus after delivery.

On July 7th, 1926, a letter was received at St. Thomas's Hospital from a practitioner asking for the admission of a patient, a multipara, aged 30, who had been delivered of her fifth child three days previously. The four previous confinements had been normal except the last, in which the placenta was removed manually. In addition there had been two miscarriages.

The medical man had apparently been called in when labour was well advanced. He found a breech presentation. The membrane ruptured early and a full-time living child *stated to be 12 lb.* in weight, was born after a normal labour of 18 hours. There was some delay in the birth of the placenta and when it did come (to quote the doctor's letter) "the uterus, placenta, and a tumour were so inextricably mixed up and the neck of the uterus so friable, that I removed them all." Unfortunately this unusual specimen was thrown on the fire and so destroyed. The method of removing the mass was to cut through such attachments as remained with scissors. It was on the third day after delivery that the doctor made his request for the admission of the patient, which was arranged for at once.

On examination after admission the temperature was 99° F., *the pulse-rate 120, and the* respirations 24 per minute. The patient looked extremely pale and feeble. She did not complain of great pain, but had a certain amount of abdominal discomfort together with severe *thirst.* The abdomen was slightly distended in the lower part and tender, and no uterus was palpable. There was a blood-stained discharge, not much more in amount *than the normal* lochia, and not offensive.

As there was no hæmorrhage and it was three days since delivery, *the patient was merely* given a sedative and propped up in bed. On the following day she had a much more anxious appearance and complained of abdominal pain. *The temperature* was 98°. A constant flow of bright blood per vaginam, accompanied by a rise in the pulse-rate, indicated the need for further investigation. An anæsthetic was given and examination by speculum made with the patient in the lithotomy position. At the top of the vagina was a ragged hole, which was gently explored when coils of gut were made out lying above. On the right of the tear was a piece of decomposing muscular tissue about 1 inch square, apparently all that remained of the uterus. From its attachment to the vagina it was thought to be the remains of the cervix and was removed for microscopy. The report returned was that it showed necrosis of tissue with enormous dilatation of vessels and extreme congestion, but that its histological structure could not be determined (Prof. L. S. Dudgeon). *The hole in the vault and* the vagina were lightly plugged with gauze wrung out of 1 in 1000 formalin solution and the patient put back to bed. *There was no further bleeding and the plug* was removed four days later. The patient was discharged on July 30th, having made an uneventful recovery.

She was seen again on Nov. 12th and found perfectly well and able to do her work. There was no pain or tenderness in the abdomen and no trouble with the bowels. There was no discharge, and on vaginal examination the tear was found to have healed up leaving a puckered scar in the vault.

Discussion.

It is unfortunate that the specimen as removed was not available for examination, as it would have been interesting to have been able to give a description of the "tumour." Probably there was complete inversion of the uterus with extensive laceration of the vagina, so that traction on the placenta while it still attached to the uterus would result in further tearing and separation of that organ from its surrounding structures The removal would then be completed by the scissors as described by the practitioner

The most striking feature is the absence of serious and rapidly fatal hæmorrhage in consequence of the tearing of the vessels, the retraction of which would be readily permitted by the loose nature of the pelvic cellular tissue which is characteristic of late pregnancy The low blood pressure resulting from the shock of the avulsion might be a contributory factor

Apart from early death from hæmorrhage or shock (or the two together), the other danger is that of the development of general peritonitis The risk is not, however, as great as might be thought, for the state of affairs differs little from that in vaginal hysterectomy, such as used to be performed for uterine cancer with its foul ulcerating surface General peritonitis was a rare complication of vaginal hysterectomy for cancer, although the chances of infection were much greater. In this case there probably was nothing more than a slight pelvic peritonitis—the signs of which decided the practitioner in charge to ask for the patient's admission to hospital All that was found on examination was slight distension and tenderness of the lower part of the abdomen In the absence of any indications for interference, the patient was merely propped up in the Fowler position, and had it not been for the bleeding that began on the following day nothing further would have been done The fresh hæmorrhage made thorough investigation necessary Only slight oozing was discovered which was readily controlled by a gauze plug

Remarks by DR JOHN S FAIRBAIRN.

The chief interest in cases of avulsion of the uterus after labour is a forensic one, because rare though they are, sufficient numbers are recorded in medical literature to show that the disaster may occur without evidence of undue force being used or of anything that necessarily involves criminal negligence

There are two papers easy of access in which details of other cases may be referred to The first is by the late Mr J Hopkins Walters, of Reading on Post-partum Avulsion of the Uterus, with a case, followed by Recovery,[1] and the other is by Dr Herbert R Spencer on Rupture and Avulsion of the Uterus at the Time of Labour,[2] in which seven cases of recovery without operation are recorded The latter paper was published after the quashing by the Court of Appeal of the conviction of a medical man for manslaughter in a case in which this accident had occurred The report of the proceedings in the High Court of that trial showed that the judge and jury were both unconvinced by the medical evidence that this accident might occur without great violence being used, and still more by the evidence that once it had occurred the proper treatment was to leave things alone unless there was hæmorrhage or other urgent reason for interference

A study of these recorded cases brings out certain points that are worth while recapitulating, because at any time criminal negligence or even a charge of manslaughter may be brought against medical practitioners or midwives who have been in attendance on the patient

The main point is that rupture of the vagina may occur spontaneously without internal manipulations, once started, the tearing may readily extend into the loose cellular planes around the cervix and lower uterine segment, and result in the complete separation of the uterus from the bladder and pelvic wall through the base of the broad ligament If the placenta is adherent or its separation and expulsion delayed, and a hand is passed up for its extraction, the detachment of the uterus may be readily effected if the extensive vaginal laceration is not immediately recognised—by no means an easy matter at the end of labour. Should, in addition, there be inversion of the uterus—whether spontaneous or the result of efforts at expression of the placenta—diagnosis is rendered much more difficult, because this rare and unexpected accident is frequently mistaken for a tumour, as is surmised to have happened in the case now recorded In one of the German cases in which a doctor was called in after the midwife had attempted to remove the after-birth manually and found the patient bleeding and collapsed, he found a large body, round which he could move his hand without feeling any adhesions and, being in doubt as to what it was, brought it out and found it was the uterus and appendages attached only to the vagina at a few points The patient recovered The unfortunate practitioner was suspended from practice and imprisoned for some months by the wisdom of the Teutonic law, whilst the midwife, clearly the cause of the disaster, escaped The most remarkable case is that recorded by Cooke in 1835 (Walters's paper, p 250) The labour was protracted (63 hours) and there was considerable hæmorrhage during the following night; 33 hours after the spontaneous delivery of child and afterbirth, the midwife was recalled because the patient had got out of bed to pass water, had screamed, and called for assistance, and was discovered sitting on a stool with a large substance between her thighs supported by her hands When the midwife arrived the patient was in bed, the large substance was connected by a shred of membrane only, was removed, and was found by the recorder of the case to be the inverted uterus with all its appendages, except the left ovary The patient survived without further treatment. The explanation given of this case is that the inverted and partially separated uterus was expelled during straining at stool, further separation occurred from the drag of the dependant mass while the patient was got back to bed, and the midwife's story, supported by husband and relatives, that only a few membranous tags remained, is accepted as reliable.

Another trial for manslaughter in this country is quoted by Walters (Popplewell, 1868), and in the discussion subsequent to the reading of his paper he said, in reply, that no penal action was taken against the midwife responsible for the case he recorded, and that he was thankful this was so, as he would at the time have given much stronger and more positive evidence against her than his further study of the subject would have justified

These disasters are happily so rare that even those of us with the widest hospital experience are unlikely to meet with more than an occasional case, so that evidence based on personal knowledge alone will not be convincing to the court, as is shown in the report of the manslaughter trial at the end of 1924 [3]

This record and references to others are made in the hope of lessening the chances of another verdict like that in the case just mentioned

[3] THE LANCET Special Supplement, Feb 14th, 1925

EXTENSION OF HOSPITALS —The Blackpool Victoria Hospital is to be renovated and enlarged at a cost of about £100,000 Additional accommodation will be provided for approximately 200 patients, and a ward for paying patients is included in the scheme —The sum of £20,000 is to be raised to equip the Chester Infirmary with apparatus for the treatment of cancer The adjacent counties of Cheshire, Flintshire, and Denbighshire will be invited to coöperate —The first block of the new Bradford Royal Infirmary at Daisy Hill is to be begun at once The cost of the whole institution will be about £500,000 It has been stated that there is no town or city in England in which the workers subscribe a larger sum per head than they do in Bradford to the hospital and convalescent fund Last year £20,000 was raised amongst the workers for distribution to the voluntary hospitals, and 1100 people were sent to convalescent homes —A fund is to be opened for the remodelling of Denbigh Infirmary, which is one of the oldest hospitals in North Wales

ON THE VALUE OF PRESENT METHODS OF TREATING LEPROSY.*

By H W. WADE, M D. Tulane.
AND
C. B. LARA, M.D Manila,
CHIEF PATHOLOGIST AND CHIEF PHYSICIAN RESPECTIVELY, CULION LEPER COLONY, PHILIPPINE HEALTH SERVICE

It is now many years since the outlook in leprosy work was such that there seemed little hope of finding an effective treatment Various drugs were reported as beneficial, but few gave any apparent cures, and there was usually doubt lest these were but temporary retrogressions or if permanent, were due to factors other than treatment At present, those actively engaged in or familiar with modern leprosy work on a large scale have, as a rule, a much less pessimistic outlook However, from others one occasionally hears expressions reminiscent of the cheerless past It may be well, therefore to take stock, to inquire whether one's own more optimistic view is really justified.

Because the anti-leprosy work in the Philippine Islands is so largely an attempt at eradication and treatment, and because it was here that what may be considered the transition period began with the Heiser-Mercado treatment, it may be of special interest to compare as well as we may the results now being obtained with those of the recent past In this connexion certain other pertinent matters will be touched on

Definition of "Leper."

The term "leper" is often applied without qualification to cases that are of three main classes It has long been applied by some to anyone who shows evidence of ever having had leprosy, whether the actual disease still exists or not In the asylums of some regions the old, crippled "ex-lepers" are particularly conspicuous For all scientific purposes such cases should be distinguished from those with the active disease

Of the latter there are two groups In those most commonly seen the bacilli can be demonstrated Only such cases can be held for segregation under Philippine regulations, and Philippine reports have dealt almost solely with such cases. Because of the degree of advancement when first seen, these are at best only fairly favourable material for treatment, and usually they are decidedly otherwise.

The other group, which has recently begun to receive due attention largely because of Muir's insistence, comprises those who present only clinical evidences of the disease Such persons we prefer to call "suspects," or when the diagnosis is reasonably certain, "clinical lepers"

When these basic distinctions are not used it is impossible fairly to compare different reports on treatment work The results obtained, should suspects and clinical lepers be recorded unqualifiedly as lepers, may be expected to be comparatively spectacular, which may unnecessarily excite incredulous scepticism in the minds of physicians who treat only bacteriologically positive cases There is of course greater possibility of error in diagnosing the bacteriologically negative group, though with careful properly trained workers this is not important

Previous System and Treatment

At the time of the opening of the Culion Leper Colony in 1906, lacking a reasonably *effective treatment* the only available anti-leprosy measure was segregation of bacteriologically positive cases It were out of place here to discuss at length the effectiveness of this measure Suffice it to quote the following official statement:—

> "Revenges and anonymous letters are the best sources of information to localise detected cases of leprosy, though some lepers are identified in fiestas and sometimes in the public dispensaries"[1]

While this statement is probably too sweeping, it nevertheless has an important basis of fact, which is to be considered in connexion with claims of critics of the segregation measure that this has been applied intensively and ruthlessly.

Until recently treatment has been an unimportant factor in the eradication campaign in the Philippines, if indeed it was a factor at all Of the earlier treatment work here only a few points need be touched on In 1908 Heiser introduced, both at Manila and Culion, Dyer's method of using chaulmoogra oil by mouth. A number of patients became negative, but it is stated that none remained so for two years Injection experiments were unsatisfactory until the development of the well-known mixture of Mercado, who was house physician at the San Lazaro Hospital, Manila Several cases having become negative, systematic work was begun early in 1912,[2] and the treatment was shortly introduced at Culion According to Mercado,[3] from 1910 to 1912 he gave the treatment to 52 patients, 24 of whom "recovered, blood negative" Apparently most of these relapsed, for only four treated cases were released in 1913, after being negative for two years These were the first so to be released though one other recovery had previously occurred, spontaneously, at Culion Two more treated patients were discharged from San Lazaro in 1915, and 23 from Culion All of the latter group showed neutral stigmata suggesting that treatment had been aided by a comparatively high tendency to spontaneous recovery.

The only indication of quantitative results obtained during this period is that of 30 selected cases treated at San Lazaro by a special committee appointed in 1914, six had become negative before the end of two years We are unable to say how many of these were ultimately released After 1915 comparatively few patients were held at San Lazaro for continued treatment

As is the common experience enthusiasm on the part of the patients tended to wane In 1915 1500 received treatment at Culion (apparently weekly) Later reports were to the effect that attendance was declining and in 1919 an average of only 700 injections were given weekly No record is available of the total numbers who took treatment, but it was undoubtedly less than half and at that time perhaps only one-third of the total population, which was about 4500 in 1919 In 1922 the same number of treatments were being given with about 5000 in the colony Though the treatment was at least beneficial to most of those who could take it energetically and persistently, and probably increased the average length of life, most patients were irregular in attendance for the medicament was often so irritating to the tissues that the treatment was decidedly heroic

To ascertain the number of cases discharged between 1916 and the present period, various records have been examined, especially those of the official committee on diagnosis, on which one of us served from 1916 to 1922 Absolute accuracy for one or two of the years is not possible but the figures in Table I. are essentially correct

Excluding the 20 discharged previous to 1916, the treatment work with the Mercado mixture produced 59 discharged cases in six years, an average of 10 a year.

TABLE I —*Treated Cases Discharged from San Lazaro Hospital, Manila, and the Culion Leper Colony, to 1922* (*a*).

	Previous	1915	1916	1917	1918	1919	1920	1921.	Total
San Lazaro	4	2	4(*c*)	14	5	2	2	9	42
Culion	(*b*)	23	4	1	4	0	12	2	46
Total	4	25	8	15	9	2	14	11	88

(*a*) Discharged cases that had become negative at San Lazaro in 1920 (Mercado treatment) and in 1921, and a number of Mercado cases discharged from Culion early in 1922, appear in the figures of Cavino and Tietze (Table II)

(*b*) One case, spontaneously recovered

(*c*) Not including five patients eloped after one negative examination

Present System.

The whole situation has changed since the advent of modern treatment methods, so much so that the general plan of the anti-leprosy campaign in the Philippines has evolved to a three-phase one, in which both treatment and segregation play leading rôles.

Two phases have to do with the handling of segregated cases (1) Those more hopeful of successful treatment are to be kept for that purpose in regional treatment stations of the hospital or asylum type, this will permit close supervision, will provide the most encouraging milieu possible, and will meet in part the objection to segregation in a distant place. (2) Those proven unfavourable for effective treatment are to be transferred to the Culion Colony where they can lead more normal lives, here those who are suitable will continue to receive such treatment.

The other phase, which it is hoped will be started in 1927, is to be the searching out and dispensary treatment of clinically positive but bacteriologically negative cases This is the activity on which Muir places so much importance for India. If it can be carried out thoroughly it will undoubtedly greatly hasten the reduction of leprosy, but the practical difficulties are such that it will require workers of unusual enthusiasm and personality to overcome them.

At present the system is in transition Only at Manila and Cebu are there quarters that can be used as treatment stations even to a limited extent. Such of the favourable cases collected there as can be accommodated are held for continued treatment, the rest being sent to Culion All cases found in other regions are still sent here direct Negatives are no longer all held until they can be discharged after the two-year negative period; under certain conditions they may be parolled after six months, to return weekly for treatment and examination Discharges and paroles are made from Cebu as well as Manila, a second committee for diagnosis having been appointed at the former place

Present Treatment and Results

With regard to the preparations now used, it is sufficient to say that the mixed chaulmoogra ethyl esters constitute the chief medicament, for the most part with iodine added to reduce irritation (0 5 per cent heated until brown) Weekly intramuscular injection is the almost universal rule

It is not practicable to present the results in such a summary as may be desirable, for more or less continuous treatment work is being done in three places, and patients are being discharged from two, the work in these places not being closely coordinated It is therefore preferable to deal separately with each centre of activity.

1. *San Lazaro Hospital*—Here experiments with the newer methods were begun on a small scale in July, 1920, primarily with the sodium salts introduced by Rogers, the ethyl esters being added shortly thereafter In due course the old treatment was generally abandoned, the ethyl esters being then used almost exclusively The results obtained here have been summarised by Cavino and Tietze[4] The pertinent figures, with recent additions, are given in Table II.

TABLE II —*Numbers of Patients Treated, becoming Negative, &c, at San Lazaro Hospital, Manila, 1921 to 1924 inclusive**

	1921	1922	1923	1924	1925
Total patients treated	443	606	642	650	649
(*a*) Admitted during the year	302	391	339	303	244
(*b*) Previously admitted	141	215	203	347	405
No treated in previous year, now transferred to Culion, &c	211	230	401	295	374
Number becoming negative during year	21	32	36	84	183
Number discharged or parolled	—	18	62	35	150

* Adapted from report by Cavino and Tietze Data from 1925 recently furnished, personal communication Figures for cases under treatment in 1920 omitted since comparatively few received the newer preparations, and those for only six months

From this summary it is seen that in five years, 1921–25 inclusive, a total of 250 (average 50 per year) bacteriologically positive cases became negative During the first four years 115 (including probably 20 to 25 that became negative under the old treatment) had been discharged or parolled The surprisingly large number released in 1925 (150) these workers ascribe to the fact that maximum results are obtained only after long periods of treatment

It is to be realised that since San Lazaro Hospital is primarily a collecting station, with insufficient accommodation for retention of all patients eligible to stay there under the plan, much of the population has been shifting This is to some extent disadvantageous, but on the whole it has probably been otherwise, permitting better selection of cases The reporters wisely refrain from drawing statistical conclusions from their data The duration of the disease in these cases is not discussed However, data as accurate as can be hoped for were got by Callender and Bittermann,[5] who carefully questioned a representative group of 259 patients during this period. The average was 2 65 years (corrected figure).

It is to be pointed out that the above figures cannot fairly be compared directly with those in Table I, for in the earlier period comparatively few patients were held at San Lazaro for continuous treatment However, it is not without significance that San Lazaro alone releases several times as many per year as Culion and San Lazaro together formerly did.

2. *Cebu Detention Camp*—This has been less a treatment station than has San Lazaro, as relatively fewer patients could be held for continuous treatment Nevertheless, a not inconsiderable number of patients have been parolled from here, as is seen from Table *III*.

TABLE III —*Data on Treatment Work at Cebu Detention Camp* †

	1923	1924	1925
Remaining from previous year	24	64	104
Collected during year	265	189(*a*)	165
Total	289	253	269
Transferred to Culion	202	84	152
Died, escaped, &c	5	15	7
Released (parole)	18	50	8
Remaining (incl negatives)	64	104	102
Total	289	253	269

† From the (unpublished) Annual Reports of the District Health Officer, Province of Cebu for 1923 and 1924, Dr S A Chiyuto, now Chief, Culion Leper Colony, for 1925, Dr Agusano

(*a*) Certain discrepancies in this report make the accuracy of these figures questionable

---

[4] Cavino, C, and Tietse, S Jour Phil Is Med Assoc 1925, v, 50, also personal communication

[5] Callender, C R, and Bittermann, T Phil Jour Sci., 1925, xxvii, 9

The total figures for admission, &c , are not of importance here except to emphasise the large turnover in this institution In view of this, the number parolled, totalling 76 in three years, is creditable It is to be said that the small number parolled in 1925 is probably due to a tendency of patients to abuse the parole privileges by not returning regularly for weekly injections

3 *Culion Leper Colony* —New work was started here in the middle of 1921, with 500 cases Most of them received ethyl esters, but groups of 50 each received sodium gynocardate and sodium morrhuate, and a control 100 the Heiser-Mercado treatment By the beginning of 1922 1000 cases were under treatment, the ethyl esters being used almost exclusively. Increased appropriations, further augmented because of the keen interest taken in the matter by Governor-General Wood, made it possible greatly to expand the activity, and by the end of that year a total of 4458 cases had been, for a time at least, under treatment The average duration of the disease in these was about eight years,[6] certainly too long for systematic —i e , "cutaneous" and "mixed" cases to be considered favourable treatment material

Since then there has naturally been much change Many patients have proved, or become, unsuitable for treatment Death has unavoidably taken its quota New patients have been brought in (total 1630, 1923 to 1925 inclusive), and all suitable cases have been treated The exact total involved cannot be stated, but it is less than the total of the total figures given—i e , somewhat less than 6000

We will not discuss the results in terms of percentages improved Important as this is, the final test of effectiveness of treatment is the ability to carry improvement to the point of causing bacteriologically positive cases to become negative, and to remain so To date (Nov 1st, 1926) 358 patients have been discharged or parolled, 27 have died while in the negative period, and there are (Nov 1st, 1926) 244 negatives now undergoing observation, bringing the total to 629 This is about 10 5 per cent of all cases treated

When this can be done in a leper colony, where the patients are bacillus-positive, very few early, and many proven unsuitable for treatment, where they live scattered over a wide area, and so not under close control, where many cannot be persuaded to deny themselves the harmful indulgence of marriage or its equivalent, and where they are constantly associated with discouraging, hopeless cases, it must, we feel, be admitted that an important advance has been made in leprosy treatment

Relapses

With reference to what actually constitutes a relapse the experience of the first three years work at Culion, investigated by one of us from the viewpoint of the bacteriologist, emphasised the following basic principle —

The disappearance of bacilli in patients improving under treatment being a gradual process, at some stage it will become a matter of chance whether any of the remaining bacilli will be found in material taken for examination, and thereafter the chance will decrease progressively Consequently, it is practically unavoidable that some patients be declared negative earlier than they should be, and that at least some of these should suffer interruption of that period because of subsequent positive findings Such cases in the absence of *definite indication of reactivation of the disease* should not be considered relapses

These and other considerations emphasise the necessity of repeated careful standard examinations before declaring a patient negative, continued treatment and repeated examinations for a definite period (two years) thereafter, and occasional examinations for several years more [7]

Of the experience in the earliest period of Philippine work, Heiser stated that no treatment had caused any patients to remain bacteriologically negative for two years previous to the use of the Mercado mixture Better as this was, an unfortunately large proportion of negatives relapsed, not a few of them permanently Several so relapsed at the end of the two-year period or after release Unfortunately, accurate data cannot be worked out from available records.

Culion records showed, in October, 1925, that of the 508 patients who had then been put on the negative list since 1922, 15 per cent (75) had at some time been removed because again found bacteriologically positive One-third of these had already been returned negative In less than half of the instances (ratio 29 35) was any clinical evidence of reactivation recorded In several instances the interruptions were clearly due to overlooking in the first instance some region that should have been examined bacteriologically, this was before a systematic record card had been introduced

According to calculations based on the data obtained some 60 of the 246 who had been parolled or discharged up to that time might be expected to be found at least bacteriologically positive Actually, of the 358 that have now been sent out (November 1926) only four have been sent back to Culion, one out of 115 discharged, three out of 245 parolled One other is held at San Lazaro Unfortunately, we cannot stress these figures It is known that the released cases have not been thoroughly followed up. However, there is, to our minds, no doubt whatever that actual relapse is now relatively much less frequent than in the past

Discussion

To compare the totals indicated above, 88 discharged cases (1913 to 1921) with 684 (1922 to 1926), would not be a valid measure of the greater effectiveness of the newer preparations, for treatment work is now much more extensive and intensive than in the past, and the former figure includes only cases discharged after a two-year negative period, "parole" not being granted at that time However, we have been satisfied, from the results of direct comparative trials both at San Lazaro and at Culion, that the ethyl esters can be employed more effectively than the Mercado mixture For, while the action of each of these preparations depends on the same active principles, a given dose of the former is much smaller in bulk and less irritating locally than an equivalent dose of the oil-mixture and is more readily absorbed, as shown both by clinical observation and by experimentation [8]

The present view is that for large-scale work the modern treatment methods are decidedly superior to the older ones, and that they seem to be particularly effective in early cases Though they are admittedly much less effective in well-established advanced cases, the results obtained in the Philippine Islands during the last few years show that a not inconsiderable proportion of such cases (probably 15 to 20 per cent) can be "apparently cured" if treated intensively under proper conditions This is a noteworthy advance, however discouraging to anyone treating any particular small group of unselected cases In view of the impressive total, which all 1926 releases will bring to 800 or more, one cannot, we submit, deny the relative effectiveness of present treatment, or its absolute value in properly selected cases It were quite as correct to deny the value of surgery in cancer In leprosy, as in cancer, emphasis must be laid on getting the patient early It is from this viewpoint that treatment is now revolutionising anti-leprosy campaign systems produced 59 discharged cases in six years, an average of 10 a year.

Present Treatment and Results

With regard to the *preparations* now used, it is sufficient to say that the mixed chaulmoogra ethyl esters constitute the chief medicament, for the most part with iodine added to reduce irritation (0 5 per cent heated until brown) Weekly intramuscular injection is the almost universal rule

It is not practicable to present the results in such a summary as may be desirable, for more or less continuous treatment work is being done in three places, and patients are being discharged from two, the work in these places not being closely coordinated It is therefore preferable to deal separately with each centre of activity

1. *San Lazaro Hospital*—Here experiments with the newer methods were begun on a small scale in July, 1920, primarily with the sodium salts introduced by Rogers, the ethyl esters being added shortly thereafter In due course the old treatment was generally abandoned, the ethyl esters being then used almost exclusively The results obtained here have been summarised by Cavino and Tietze[4] The pertinent figures, with recent additions, are given in Table II.

TABLE II —*Numbers of Patients Treated, becoming Negative, &c , at San Lazaro Hospital, Manila, 1921 to 1924 inclusive* *

	1921	1922	1923	1924	1925
Total patients treated	443	606	642	650	649
(*a*) Admitted during the year	302	391	339	303	244
(*b*) Previously admitted	141	215	203	347	405
No treated in previous year, now transferred to Culion, &c	211	230	401	295	374
Number becoming negative during year	21	32	36	84	183
Number discharged or parolled	—	18	62	35	150

* Adapted from report by Cavino and Tietze Data from 1925 recently furnished, personal communication Figures for cases under treatment in 1920 omitted since comparatively few received the newer preparations, and those for only six months

From this summary it is seen that in five years, 1921–25 inclusive, a total of 250 (average 50 per year) bacteriologically positive cases became negative During the first four years 115 (including probably 20 to 25 that became negative under the old treatment) had been discharged or parolled The surprisingly large number released in 1925 (150) these workers ascribe to the fact that maximum results are obtained only after long periods of treatment

It is to be realised that since San Lazaro Hospital is primarily a collecting station, with insufficient accommodation for retention of all patients eligible to stay there under the plan, much of the population has been shifting. This is to some extent disadvantageous, but on the whole it has probably been otherwise, permitting better selection of cases The reporters wisely refrain from drawing statistical conclusions from their data The duration of the disease in these cases is not discussed However, data as accurate as can be hoped for were got by Callender and Bittermann,[5] who carefully questioned a representative group of 259 patients during this period The average was 2 65 years (corrected figure)

It is to be pointed out that the above figures cannot fairly be compared directly with those in Table I, for in the earlier period comparatively few patients were held at San Lazaro for continuous treatment However, it is not without significance that San Lazaro alone releases several times as many per year as Culion and San Lazaro together formerly did.

2. *Cebu Detention Camp*—This has been less a treatment station than has San Lazaro, as relatively fewer patients could be held for continuous treatment Nevertheless, a not inconsiderable number of patients have been parolled from here, as is seen from Table III

TABLE III —*Data on Treatment Work at Cebu Detention Camp* †

[5] Callender, C R, and Bittermann, T. *Phil* Jour Sci, *1925*, xxvii, 9

A daily evacuation of the bowels should be secured, and, needless to say, regular bathing of the skin must not be neglected The heart must be examined at every visit, not only by auscultation, but also by light percussion, by means of which evidence of dilatation will usually be detected, long before a murmur can be heard It is strange that percussion of the heart in children is so little practised, and yet it is of fundamental importance in such cases

How long must the patient be in bed ? Very often six weeks is not too long a period Much depends on the severity of the case and on the amount of involvement of the heart This being so, we must, to some extent, compensate for the enforced want of real activity by making use of massage Massage in such cases not only keeps up the nutrition of the limbs, but actually aids in checking the choreic movements if regularly and properly carried out To be of value it should be gentle, and stroking rather than kneading movements should be employed by the operator The child will often sleep better if the massage is carried out in the evening , and, in any case, it should be done twice a day, if possible

During convalescence attention should be devoted to the heart It is always well to give gr 5 of one of the salicylate group along with gr 5 or 10 of the saccharated carbonate of iron for several weeks thrice daily Nux vomica and cod-liver oil are also of great value in restoring nutrition Return to school should be delayed for at least three, and preferably for six, months Watch must be kept throughout for any signs of pains in the limbs or joints, for sore-throat, or, indeed, for any other possible rheumatic manifestation The patient should have the heart examined by the medical attendant at least once in six months as long as may be considered necessary I have met with many cases of heart affection in adults traceable to chorea in childhood where no after-care had been taken Is it too much to state that not a few of these cases might have escaped any serious heart involvement if greater attention had been paid to them during the convalescent period and in the years thereafter ?

A CASE OF

PETECHIAL HÆMORRHAGES

ON THE LUNGS AND HEART OF AN UNBORN CHILD

By Sydney Smith, M D. Edin , D P H ,
PRINCIPAL MEDICO-LEGAL EXPERT, EGYPTIAN GOVERNMENT SERVICE

The following case is worthy of record

A young woman, eight to eight and a half months pregnant, received a blow on the head from a heavy stick and died shortly after She was examined at the medico-legal mortuary on the following day, and the fœtus was removed from the uterus On examination of the thoracic organs of the child numerous petechial hæmorrhages were observed on the anterior surface of the heart and aorta and over the right and left lungs They were scattered over the whole surface of the lung, but were more intense on the surfaces in contact with heart and on the interlobar surfaces. The hæmorrhages varied in size from small pin-pricks to spots the size of a pin's head The surface of the left lung had a slightly mottled appearance in the upper lobe, but as a whole the lungs looked as though they had never respired They sank when placed in water On microscopic section no trace of vesicles could be observed, but under the pleura and scattered throughout the whole of the lung tissue there were numerous hæmorrhages These were by no means petechial but took up quite a large part of the section Numbers of greatly dilated capillaries could be observed and these were in many cases surrounded by blood In certain places hæmorrhages could be traced from the lung tissue to the pleura There was no sign of organisation of the blood or other change in the tissues of the lung

The other organs of the child and the organs of the mother were healthy

The case has some medico-legal interest, for the appearance of the lungs was exactly similar to the condition found after asphyxia by violence The origin of the hæmorrhages is not easily explained It is obvious that rupture of capillaries must be the result either of excessive blood pressure or of damage to the vascular walls or both In this case damage to the capillaries is not likely to have occurred as the death of the mother took place within a few minutes, and she was previously in normal state of health Increase of blood pressure must therefore be the principal causal factor, and it is of interest to ascertain in what manner this might produce the conditions found.

When the mother died the fœtal blood circulating in the placenta would be deprived of its oxygen and remain charged with the products of metabolism If vasomotor control in the fœtus is operative, this would cause an increase in blood pressure, and I suggest that this case gives some justification for the assumption that the centre is operative in the fœtus

In the fœtal circulation, it will be remembered, oxygenated blood from the placenta passes by the inferior vena cava to the right auricle, and is directed across this chamber and passes through the foramen ovale into the left auricle Impure blood from the upper part of the body passes by the superior vena cava into the right auricle, and after mixing slightly with the blood from the inferior vena cava, passes to the right ventricle through the tricuspid valve This impure blood then passes to the pulmonary artery and after a small quantity is distributed to the lungs by the right and left branches, the main bulk of the blood enters the aorta by means of the ductus arteriosis The normal blood pressure in the pulmonary artery and right side of the heart must be greater than the pressure in the aorta and left ventricle, otherwise it would not be possible for the blood in the pulmonary artery to be forced into the aorta

If, now, anything occurs which stimulates the vasomotor centre, the increase of pressure will occur only in the systemic circulation, for the pulmonary circulation is not controlled by this centre A point may thus be reached where the pressure in the aorta is equal to the pressure in the pulmonary artery, and the full quantity of blood in the latter, instead of finding an outlet into the aorta through the ductus arteriosis, must be forced through the lung capillaries. This increase in volume of blood would naturally cause dilatation of the capillaries, and numerous hæmorrhages by rupture would result The condition found microscopically would thus be reproduced

TWO CASES OF

STREPTOCOCCAL EMPYEMA TREATED BY CONTINUOUS ASPIRATION

By H Ferguson Turney, M B Oxf ,
M R C P Lond ,
LATE HOUSE PHYSICIAN AND ASSISTANT CASUALTY MEDICAL OFFICER, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, LONDON

The treatment of empyema by continuous aspiration appears to have attracted comparatively little notice in recent discussions on the subject , hence the following two cases treated by this method are worthy of record, especially as both were streptococcal in origin The technique used was fully described by F J Poynton and F N Reynolds [1] Briefly it consists in introducing a short silver cannula between the ribs by means of a trocar, novocaine anæsthesia being used A tight-fitting rubber catheter is then passed through the cannula, and suction is applied by means of a water pump The only modification of the original method was the use of an elastic rubber belt to keep the cannula in place, and this was found far more effective than tapes

The two following cases were admitted on successive days to the Hospital for Sick Children, under the care of Dr F J Poynton

Case 1 —A boy aged 6 years and 2 months The history began with broncho-pneumonia on Dec 27th, 1925, the

Clinical and Laboratory Notes.

A CASE OF
SEVERE CHOREA ASSOCIATED WITH TAPEWORM,
WITH REMARKS ON THE TREATMENT OF THIS DISEASE

By JAMES BURNET, M D , F R C P EDIN ,
LECTURER ON DISEASES OF CHILDREN, SCHOOL OF MEDICINE OF THE ROYAL COLLEGES, EDINBURGH

THE special interest of the following case lies in the fact that the patient was distinctly rheumatic, although the movements ceased almost as soon as the tapeworm was passed

The patient was a girl aged 9½ years Both parents were rheumatic The father had suffered in early life from acute rheumatism, and the mother suffered at times from pains in the shoulders and ankles An only brother, aged 12, had a severe attack of acute rheumatism at the age of 10, which affected the heart The patient herself had had frequent attacks of sore-throat, and a year previously had a slight attack of chorea

When first seen she had been ill for about ten days She was confined to bed, and her movements were extremely violent, so much so that on two occasions she had fallen on to the floor Her face was abraded from constant rubbing on the pillows, and one of her elbows was skinned She jerked her head, arms, and legs continuously so that she could only be restrained with the greatest difficulty Under the circumstances feeding had become almost impossible The temperature was 102 6° F , rising to 103° F towards evening The pulse was very rapid, feeble, and somewhat irregular The average rate was between 140 and 150 Respiration was very difficult and irregular The patient took no notice when spoken to, and looked extremely haggard and pale Examination of the heart, which was by no means easy, revealed a considerable amount of enlargement and a definite systolic bruit at the apex

As the bowels had not acted for five days an enema was given, which yielded a good result After this the girl was given chloral hydrate gr 10 per rectum, and this dose was repeated in six hours At the same time salicylate of soda gr 10 4-hourly was ordered, and she was put between blankets on a water-bed Next day the temperature fell, but the movements remained quite as severe, and the possibility of tapeworm was accordingly thought of Some years ago I had published three cases of chorea associated with tapeworm,[1] but since then I had not met another case of the kind In this case the association existed, and early in the morning she was given half a drachm of ext. filicis liq in warm milk Four hours later a dose of magnesium sulphate was administered, and in the forenoon she passed a large tapeworm Unfortunately the head could not be found

On the evening of the same day the movements were markedly lessened The temperature had fallen to 99 4° F , and the child for the first time spoke She asked for water, and wished to sit up in bed From then onwards she made an uneventful recovery She was, however, kept in bed and given salicylate of soda for nearly a month, during which time the condition of the heart gradually righted itself She was then ordered iron and cod-liver oil

Had this child been treated by means of arsenic recovery could not have taken place The case emphasises the importance of determining the exact cause, especially in severe cases of chorea, even in subjects known to be rheumatic This patient was definitely rheumatic, and yet the chorea was obviously started by the presence of a tapeworm Chorea seldom occurs in any but rheumatic children, and yet not every rheumatic child suffers from chorea Before it can develop there must be some exciting cause superadded to the constitutional disease This exciting cause may be school strain, the approach of puberty, fright, or, as in this case, the presence of intestinal parasites It is incumbent upon us to discover such exciting factors, and either counteract or remove them before undertaking the treatment of the chorea itself This is matter too often forgotten or neglected in such cases The result is that cure is either delayed, or at best is very imperfect

As regards the treatment of chorea itself, it is extraordinary to find how many still cling to the routine administration of arsenical preparations It is a guiding principle in therapeutics to treat, if possible, the cause of any disease In practically every case of chorea occurring in childhood we have a definite underlying constitutional condition—namely, rheumatism Surely, therefore, it is our duty in all such cases to administer one of the salicylate group of remedies There are those who maintain that there is no known drug which will actually cure chorea This is, to a certain extent, perfectly true At the same time it is incumbent on us in all such cases to give antirheumatic remedies with a view to counteracting the rheumatic influence at work In this respect, acidum acetylsalicylicum is to be preferred to salicylate of soda, as it is less likely to produce symptoms of acidosis and at the same time is rather more pleasant to take When salicylate of soda is given, it is always advisable to combine it with an equal quantity of the bicarbonate, and only the pure natural salt should be employed Another important fact to be kept in mind is that small doses are not likely to do much good. To a child of ten years not less than gr 10 either of acid acetylsalicyl or of salicylate should be administered for a single dose, and this may be repeated thrice daily or every four hours, according to the severity of the attack

If arsenic is given it should never be pushed, as is far too frequently done In fact, there can be no doubt that many so-called cases of chorea by means of this drug are due to the production of peripheral neuritis. Like other observers, I have met with several cases of this kind The usual practice is to begin with drop doses of the liquor arsenicalis, and go on gradually increasing the dose by 1 minim until 10 or even 15 minims are taken three times a day This, in my opinion, is a very dangerous practice Not only does the arsenic fail to benefit the rheumatic condition underlying the chorea, but it renders the patient liable to very bad after-effects In one case a child had been getting 15 minims of the liquor arsenicalis thrice daily for several days The choreic movements had certainly entirely ceased but the child's limbs were completely paralysed There was a mild degree of drop-ankle and drop-wrist present, and on grasping the limbs the patient winced Sometimes these symptoms do not appear at once They may be delayed until some time during the convalescent period. In one such case the onset of the neuritis did not occur until three or four weeks after the patient had been allowed out of bed If, therefore, arsenic is given, it should be administered in moderate doses, and heroic amounts, such as 10 or 15 minims, should not be approached in any case If this drug is going to benefit the case, it will certainly do so in doses ranging from 3 to 5 minims , if not, then the sooner its administration is given up the better

Other drugs which have their advocates are chloral hydrate, which appears to act best in those cases in which the sleep function is disturbed It is certainly to be preferred to bromides in such cases Sometimes, especially in younger children, phenazonum may be tried, as it certainly seems to possess a sedative and antispasmodic action , but its effects must be carefully watched The only other drug which need be mentioned is calomel This is of special value, I find, in cases where the heart is seriously involved

There are certain other points in the treatment of chorea which have to be kept in view I believe that such cases should always be treated between blankets Watch should be kept on the skin lest bedsores develop, and every care taken to prevent their occurrence Sometimes a water-bed will be necessary. In the diet, soups, eggs, custards farinaceous foods, porridge, fish, chicken, jellies, and fruit are all of value Tea with an equal amount of milk may be given Rusks, toast, bread with butter dripping, or marmalade may be allowed Care must always be taken to see that the patient's food is

---

[1] British Journal of Children's Diseases, March, 1905

Symptoms and Clinical Types —Diagnosis rested on a symptom-complex which included one or more of three cardinal symptoms — amenorrhœa, irregular uterine hæmorrhage, and abdominal pain Pain on defæcation was also an important symptom Shoulder pain was usually associated with ruptured tubes where the peritoneal cavity was suddenly flooded with blood The incidence of the symptoms was as follows . amenorrhœa 72 per cent , irregular uterine hæmorrhage, 92 per cent , abdominal pain, 97 per cent Irregular uterine hæmorrhage was associated with separation of uterine decidua, but might persist after complete expulsion of decidua or after curettage, in which case it might be due to presence of living chorionic villi Abdominal pain was generally sufficient to indicate to the patient that something was wrong , it might be lancinating, colicky, or diffuse The site of the pain generally indicated the site of the pregnancy Amenorrhœa, uterine hæmorrhage, and abdominal pain were present together in 64 per cent of cases, whilst bleeding and abdominal pain were associated in 24 per cent Amenorrhœa and abdominal pain were found in about 4 per cent , amenorrhœa and bleeding in 3 per cent , and pain alone in 3 per cent. The cases might be divided into three groups or clinical types: (1) Those in which the ovum remained in the tube, and there had been little or no hæmorrhage into the abdomen (13 per cent in this series) (2) Those in which rupture or abortion had recurred with diffuse intraperitoneal hæmorrhage (27 per cent.). (3) Those in which rupture or abortion had taken place with gradual or repeated hæmorrhage into the abdomen (60 per cent).

Treatment was surgical, and the sooner the better. It was impossible to foretell when another, and possibly fatal, hæmorrhage would occur. In the very severe cases, where the patient was pulseless and profoundly shocked, operation might be delayed for a time while treatment was directed to the shock When and if the condition of shock was relieved, operation should be undertaken immediately.

Prognosis and After-history —Prognosis was good, and was better the earlier the operation could be performed There was no disease of parallel severity in which the response to prompt surgical treatment was so rapid and so satisfactory There were no deaths in Prof Dougal's series As regards subsequent pregnancies it was found that among patients who could be traced and who had been operated on more than six months previously the results were as follows subsequent uterine pregnancies, 46 per cent ; subsequent ectopic pregnancies, 13 per cent , no subsequent pregnancy, 41 per cent The prognosis for subsequent uterine pregnancy was fairly good, but there was a serious risk of the patient having a second ectopic pregnancy In this series seven patients had had two ectopic pregnancies

Discussion

Dr. F H **LACEY** asked if there was any history of infections in the puerperium He considered that shoulder pain was usually complained of in ectopic pregnancy

Dr W W **KING** considered that rectal pain was more common than shoulder pain He strongly advised waiting in the very severe cases till the accompanying shock had been treated. He did not regard the other cases as urgent at all

Dr **LEITH MURRAY** had recently examined his series of 112 cases He had found the pregnancies more common on the right side (67) than on the left (45) He did not agree with Prof Dougal as to the terminations In his series the intratubal ruptures greatly exceeded the tubal ruptures The figures were intratubal rupture including mole abortion, 105; primary peritoneal rupture, 1; secondary peritoneal rupture, 4 , intraligamentary rupture, 2 He agreed that in the majority of cases there was evidence of pelvic disease or a history of antecedent infection Disease of the appendix might be a common predisposing factor accounting in the first place for the preponderance of cases of pregnancy on the right side. In these cases he had removed numbers of apparently normal appendices, and microscopically had found them diseased In his series a history of amenorrhœa was less often elicited, and pain was not so marked a feature

Dr. E O **CROFT** said that in his experience amenorrhœa was not so marked a symptom and pain was generally abdominal In some cases it was situated elsewhere than over the lesion.

Dr A A **GEMMELL** asked if there was any evidence of an increased number of abortions antedating these ectopic pregnancies, as in Germany it had been thought that ectopic pregnancies had increased with the increase in criminal abortion during the war.

Mr **ST GEORGE WILSON** asked if in any of the severe cases transfusion with the patient's own blood had been carried out. He had lately done this in a case of uterine rupture, with satisfactory results

Mr. W **GOUGH** agreed about the need for early operation

Prof **MILES PHILLIPS** had recently collected 150 cases with three deaths As regards the ætiology, he was of the opinion that in a number of cases ovarian disease or dysfunction was a factor

The **PRESIDENT** remarked on the preponderance of ruptures over tubal abortions and agreed with Dr Murray that in his experience it was the reverse He had operated on cases with normal tubes but cystic ovaries, and he considered that ovarian disease was a factor in the ætiology.

In reply, Prof **DOUGAL** said that he had no complete details of previous puerperal infection, but he had details of cases with previous abortions He did not approve of delay in operation in any type of case. The symptoms in unruptured cases were quite definite He agreed about the large number of cases of ectopic pregnancy on the right side, and he had operated on patients from whom the appendix had been removed previously In some cases it was difficult to decide whether there was rupture of a tube or an abortion He had not tried transfusing the patient with her own blood The ovaries, he thought, might sometimes be at fault

Fibroids after the Menopause

Dr **MURRAY**, after describing a case of infraligamentary fibromyoma removed from a woman of 60, said that in his experience fibroids rarely caused symptoms in the menopause In 540 consecutive operations for fibroids only 14 (2 6 per cent) had caused symptoms in the menopause Œdema of the fibroid was the usual cause of postmenopausal symptoms

The **PRESIDENT** remarked on the small number of postmenopausal fibroids in Dr Murray's series He had seen many cases of fibroids which had caused symptoms after the menopause

Prof **PHILLIPS** and Dr **CROFT** agreed with the President

Mr **GOUGH** remembered seeing a case of fibroids in the menopause giving rise to symptoms owing to shrinkage It had previously rested in the abdomen, and when it shrank had fallen down into the pelvis and caused retention of urine

Dr **MURRAY** also described a case of

Congenital Absence of Vagina and Cervix

A girl, aged 15, was sent to hospital with a history of abdominal pain lasting two years The pain was colicky, occurred every four to five weeks and lasted, on each occasion, about five days She had a feeling of much weight in the pelvis at those times and frequently vomited There had been no menstruation. Examination under anæsthetic on Dec 16th, 1925, showed a vulval depression which just admitted the top of the index-finger This was all that could be found to represent a vagina. The vulva and the site of the urethral orifice were normal, and the breasts and pubic hair were well developed On bimanual rectal examination no thickening such as would suggest a vagina could be found The uterus appeared to be normal in size and position ; the right ovary was readily palpated

At a perineal exploratory operation the pelvic connective tissue between the urethra and the bladder in front and the bowel behind was easily opened by a finger, after incision patient getting steadily worse until Jan 7th, 1926, when a swelling appeared on the right side of the chest On the following day the chest was aspirated and 3½ pints of pus removed On Jan 11th a similar amount was withdrawn, and on the following day a rib was resected Very little fluid was found in the chest, and only a negligible amount drained from the wound The condition getting worse, the patient was admitted to hospital on Jan 21st

On admission he was very pale and emaciated, obviously in a serious condition, and with a temperature of 102 8° F Examination of the chest suggested a pyopneumothorax under considerable pressure, both respiratory distress and displacement of the heart being very marked The operation wound was very low down, and drainage could not be established through it The chest was aspirated and several ounces of pus removed The condition at once improved and the temperature fell, but subsequently rose again, and on Jan 31st a further 8 ounces of pus were removed Again a temporary improvement occurred, but the temperature rising once more, it was decided to start continuous aspiration. This was done on Feb 5th. Pus drained away freely for the first few days, and then rapidly diminished The cannula was removed on Feb 16th and recovery was uninterrupted

A hæmolytic streptococcus was isolated from the pus

Case 2 —A boy aged 9 years and 1 month The illness began 12 days before admission, with pain in the right side of the chest On admission the boy was in a very toxic condition with a temperature of 102 4° F A needle was inserted and 3 ounces of very foul-smelling streptococcal pus removed A small abscess containing similar pus subseqently formed at the site of the puncture The temperature fell after the aspiration but rose again, and on Jan. 29th continuous aspiration was instituted Two days later the wound round the cannula became infected, probably as the result of an error of judgment in the introduction of the cannula too near to the original puncture, and the cannula had to be removed Fomentations were applied to the chest, and the wound infection rapidly cleared up

On Feb 8th a self-retaining catheter was introduced through the original puncture in order to maintain drainage, it was removed on Feb 12th as all discharge had ceased The temperature now remained normal for over a week, but on Feb 20th it began to rise again On Feb 24th continuous aspiration was again resorted to, the cannula being replaced under nitrous oxide anæsthesia Some ounces of the same foul-smelling pus drained away For the next dew days pus continued to discharge and then gradually ceased The cannula was removed on March 10th, and thereafter recovery was uneventful.

Discussion.

In both these cases a surgical opinion was obtained, and in each case, though aspiration was regarded as a mere preliminary to operation, surgical interference was subsequently found to be unnecessary Two points, on account of their practical bearing on treatment, appear worthy of further emphasis

The first of these is the failure of simple aspiration and the success of the method of continuous drainage by aspiration, which by itself suggests that this should be adopted by choice It is well known that simple aspiration is sufficient to bring about an ultimate cure in many cases of empyema, but even so it is certain that a considerable quantity of pus must be left in the pleural cavity to undergo absorption or organisation with resulting toxæmia, and the possibility of permanent impairment of the lung These disadvantages are avoided by the method of continuous aspiration, and it is interesting to note that in the cases under discussion the completeness of the recovery was confirmed by both clinical and radiological evidence

The second point is that both these cases were examples of a streptococcal infection, in which it is a matter of general agreement that open operation is essential In fact, the usual objection to all aspiration methods is that the streptococcal infections do not clear up, while in the pneumococcal types large fibrinous masses tend to be left behind, which interfere with the subsequent expansion of the lung The former objection was shown to be groundless with treatment by continuous drainage, the latter lies, perhaps, beyond the scope of this note, but there is reason for believing that such fibrinous masses undergo liquefaction and are efficiently dealt with by the same method

Lastly, the simplicity and almost painless nature of the manipulations must be emphasised Both the above patients were highly strung, nervous boys, but in neither case was any difficulty experienced in introducing the cannula, and once in position it was quite painless In addition to this, the daily dressings, so often a source of terror to children, are completely done away with

It will take time and a more extended experience before the final results by this method can be critically compared with those of open operation, but its essential superiority to any method of intermittent aspiration appears to be beyond doubt

My best thanks are due to Dr Poynton for his permission to publish these cases

Medical Societies.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY

A meeting of this Society was held at Sheffield on Feb. 25th, Prof **Fletcher Shaw**, the President, in the chair. Prof D **Dougal** read a paper on

A Hundred Cases of Ectopic Pregnancy

operated on by him during the last seven and a half years The number of operations actually performed was 105, as in five instances a second operation for a similar condition was carried out. The main features of the cases were as follows

Pathological Anatomy —The pregnancy was situated in the Fallopian tube in 103 cases In two cases of infected hæmatocele only the posterior fornix was opened In the vast majority pregnancy was early, in only two cases had the fœtus reached two months development. In 76 5 per cent of cases tubal mole was present, whilst there was no mole in the remainder. The pregnancy was on the right side in 59 per cent and on the left side in 41 per cent The terminations observed at the time of operation were as follows tubal abortion, 52 per cent, tubal rupture, 37 per cent; unruptured, 12 per cent In four cases it was impossible to give an opinion Both rupture and abortion were noted in one case

Ætiological Factors —Sixty-six per cent of cases occurred between ages of 26 and 35, the youngest patient was 21 and the oldest 43 The greatest number of cases occurred during the first five years of married life, a considerable proportion during the second five years In eight cases the patients had been married one year or less, and in all of these the ectopic was the first pregnancy Evidence of pelvic infection was noted in only one of these cases

Nearly one-third of the patients had never had a previous uterine pregnancy In those who had previously been pregnant—given that the normal interval between successive pregnancies was *not* more than three years—the interval was unduly long in 55 per cent, and it exceeded five years in 31 per cent The shortest interval was seven months

The chief predisposing cause of extra-uterine pregnancy, said Prof Dougal, was undoubtedly a previous pelvic infection which had so damaged the Fallopian tubes as to obstruct or delay the passage of the fertilised ovum to the uterine cavity Developmental abnormalities and distortion of the tubes might have a similar result, but occurred less often In certain cases—e g., gonococcal—evidence of old infection could only be obtained by microscopical examination of the tubal mucosa In this series old-standing adhesions had been present in 50 per cent of the cases The opposite tube was converted into a hydrosalpinx in seven cases and a pyosalpinx in one case The only developmental abnormality met with in this series was a bicornuate uterus, this pregnancy was situated in the right tube, and terminated by abortion Fibroids were seen in two cases calcium mechanism of the body. In making parathyroid products it was generally the external parathyroid which was utilised

Dealing with the suprarenals Dr. White cited one case of severe asthma where the patient had received at least 50,000 injections of adrenalin solution. His blood pressure to-day was probably not more than 120 systolic, so that the continued use of adrenalin had not resulted in permanent high blood pressure In fact, most of these asthmatic cases had a low blood pressure with an exaggerated vagal tone. Reference was made to the classification of hypopituitarism into pre-adolescent and post-adolescent types, and the more modern classification into deficiency of the anterior as opposed to the posterior lobe Pre-adolescent hypopituitarism involving only the anterior lobe was now referred to as of the Lorain-Levi type In this type of case the patient was of short stature the genitalia remained infantile in development, and secondary sexual characteristics were absent With the well-known type of adipose genital dystrophy (Fröhlich s syndrome) there was, in addition, girdle obesity in which the deposit of fat extended over the lower part of the abdomen to the lower third of the thigh Speaking of anterior pituitary, the lecturer reminded his audience that Gardiner-Hill claimed to have had better results in cases of defective growth in children by the combined administration of thyroid and anterior pituitary than with either of these glands alone

After speaking briefly of the recent work of Allen and Doisy in isolating the active extract from the ovary, Dr White concluded by saying that the uses of gland therapy were many and logical, but we were not likely to advance very far if we took a pessimistic view, or if on the other hand, we adopted the equally unfortunate attitude of the optimist who was prepared to prescribe gland preparations for conditions which obviously did not lend themselves to it

LIVERPOOL MEDICAL INSTITUTION.

A MEETING of this Institution was held on Feb 17th when Dr. HENRY COHEN read a paper on the

Diagnosis and Localisation of Spinal Tumours

based on 16 cases He discussed the diagnosis under three headings: (1) the gradually increasing compression of the spinal nerves and cord, (2) the site of the compression; and (3) the nature of the compression. After a general survey of the clinical features, Dr. Cohen gave a critical account of the available methods of diagnosis He dismissed the air replacement method of myelography as of no practical value, and then spoke of his experiences with heavy lipiodol introduced by the cisternal route This procedure, he said, was not without danger because of the irritation and comparative non-absorbability of the drug; he had found it present more than two years after it had been injected. Lipiodol should *not* be used he *thought*, (*a*) until a definite diagnosis of compression of the cord had been made by careful examination of signs, symptoms, and cerebro-spinal fluid; (*b*) unless exact localisation by clinical methods was impossible; and (*c*) unless an operation was to be subsequently undertaken Dr Cohen showed lantern slides illustrating the possibility of differentiating extramedullary growths by the use of lipiodol The value of light lipiodol (ascendant) was questionable After discussing the nature pathology, and differential diagnosis of spinal tumours, Dr Cohen indicated the general prognosis with regard to operative mortality, and the likelihood of recovery of function after complete removal of the tumour He pleaded for the earlier recognition of these cases in order to improve the results in a disease which when treated early, was one of surgery's greatest triumphs but if left too late resulted in the tragedy of a bed-ridden paraplegic

Dr S BARTON HALL read a paper on Blood Pressure in the Psychoneuroses, which will appear in a later issue of THE LANCET

Reviews and Notices of Books.

ALCOHOL AND LONGEVITY.

BY RAYMOND PEARL, Institute of Biological Research The Johns Hopkins University London and New York Alfred A Knopf 1926 Pp 273 15*s*

IN this book Dr. Pearl has collected together his well-known researches on the effect of alcohol on the duration of life, the main results have already appeared in short papers. That excessive drinking tends to shorten life is not in dispute, but the question remains whether regular moderate drinking, such as "a daily pint or two of beer or a daily bottle of claret or a few glasses of whisky and soda" does in fact tend to an appreciable decrease in the expectation of life Dr Pearl offers some direct evidence on this point in the form of a sample of over 5000 of the working-class population of Baltimore and Maryland. By reclassification he has met the criticism that in his original studies moderate and heavy drinkers had been classed together The material used was collected (originally for another purpose) by direct inquiry among the families concerned. As regards qualitative classification the limitations of the material available however tactfully the latter may be sought, and however willingly given are obvious, but the careful avoidance of bias in obtaining the data and the critical analysis of the results seem to justify the conclusion that in this sample moderate drinking did not shorten life The heavier drinkers, on the other hand showed heavier ratio of mortality than either the abstainers or moderate drinkers—a result in accordance with much previous life insurance experience To draw from these data the general conclusion that the moderate consumption of alcohol has no harmful biological effects would be to press them farther than they will go and the author is careful to do no more than to suggest that in his opinion this conclusion is probably true Pearl supplements this statistical evidence with a summary of the experimental work done by himself and others on the effect of alcohol on animals, birds, and insects From this he concludes that in these cases the racial effect of alcohol is preponderantly either beneficial or at least not harmful and that this beneficial effect appears to be the result primarily *of the fact* that alcohol acts as a definite but not too drastic selective agent both upon germ-cells and developing embryos The chief harmful racial effects were the production of defective offspring in early generations in guinea-pigs and some reduction in fertility. The summing up is perhaps too definite in face of the fact that in C R. Stockard's experiments with guinea-pigs the beneficial effect did not appear till the fourth generation the last four generations being unalcoholised

The book is clearly the result of a large amount of careful work, and the statistical data of moderate drinkers appears to be the first of their kind. Some minor points here and there suggest hasty writing. The statement for instance, on p 105 that in these life-tables—"a person goes out of the exposed to risk only because of death" is not accurate, as all the living go out of the exposed to risk at their age at the time of record The argument on p 107 that to start the tables at age 20 (and so include among the abstainers persons who died early but might otherwise have passed from the abstainer class to one of the drinking classes) would be to make the death-rates of the abstainers "spuriously high" is unsound so far as concerns the actual effects of drinking or not drinking, and is only valid as regards the effects of the other habits and characteristics of drinkers or persons liable at some future time to become drinkers—which is not the point under examination The side issue of the mortality of parents is also not very clearly treated, two points arise which should be dealt with separately One is the entirely "spurious" at the apex of the vulval depression The lower pole of the uterus could just be reached, but was not brought down by volsellum lest injury to the bladder or bowel resulted No suggestion of any vagina was found

The girl was kept in hospital for observation during her next periodic pain There was no question that she began to suffer severely on Dec 21st The attack was an obvious colic associated with abdominal pain, tenderness, and backache, it lasted four days and the patient was then very languid and tired On Jan 2nd, 1926, the uterus was removed together with the left appendage The fundus of the uterus was adherent to the bladder, and there was a small quantity of black uncoagulated blood in the pelvis Both appendages were lightly adherent, particularly around the tubal ostia It seemed likely that blood had on occasions been regurgitating into the peritoneum Each ovary appeared normal and neither was enlarged, the uterine body was firm and not appreciably abnormal On cutting across the broad ligaments, as soon as the uterine arteries had been divided, the uterus was completely released by finger pressure The lower pole bore no resemblance to a cervix and was uncovered by epithelium The sudden release of the uterus, after section of the broad ligaments, was very noticeable and quite unexpected, this may have been due, in some degree, to the preliminary exploration

The length of the uterus was two and a half inches On opening the cavity about 18 drops of dark fluid escaped, this was obviously under tension The cavity thereafter was found to measure one and a quarter inches, it ended blindly, and the obdurating bridge at its lower pole measured three-eighths of an inch There was no evidence of dilatation of the Fallopian tubes

Sections show no sign of cervical stroma or endocervix The endometrium is practically normal throughout except at the lowest level, where a slight tendency towards polypoidal development is evident The wall of the uterus and the obdurating bridge appear as a normal myometrium

Dr MURRAY said that he had failed to find in literature any case exactly comparable to this. According to Keibel and Mall,[1] the tubal position of the uterus formed the corpus uteri and the utero-vaginal canal the cervix and vagina, the development of these two was therefore to some extent independent It seemed remarkable, however, that the demarcation between the distal three-quarters and the remaining quarter of the whole uterine and vaginal tube should be so complete as was evident in this case Mr Stacy had read an almost similar case to the Anatomical Society in 1924

Prof DOUGAL read notes of a case of

Adhesive Vulvitis

The patient was 36 years of age, married ten and a half years, and a nullipara. Menstruation was normal Eight years previously, during a severe attack of pneumonia, she began to complain of irritation about the vulva, and the "vagina healed up" Intercourse had not been possible since, and recently she had had difficulty in micturition. Six years ago she had been curetted, and the adherent labial folds separated, but she had been no better

On examination the labia minora were found completely glued together in the midline, except at a point about the middle of the vulva, where a small opening one-eighth of an inch in diameter served for escape of menstrual blood and urine Under an anæsthetic it was found possible to separate the adherent folds without difficulty, and during separation a thin layer of desquamated epithelium was partially torn away and remained stretched across the vulval opening The area affected consisted of the inner surfaces of the labia minora and the folds about the clitoris The surfaces were disinfected and separated by a dressing, but in a few days became adherent again, so the vulva was excised, and the vagina orifice well opened up, and no labial surfaces were left in contact Seen two months afterwards, she was quite well, and there was no recurrence

Sections of the skin showed inflammatory changes in the deeper layers, and thickening and keratinisation of the squamous-celled layers

Prof PHILLIPS asked if Prof Dougal thought that the infective agent was the pneumococcus He himself had seen a case of pneumococcal endometritis in pneumonia

Prof DOUGAL said that he believed that the condition was due to the pneumococcus

Dr LACEY described a case of

Foreign Body in the Pregnant Uterus.

The patient, aged 28, had had amenorrhœa for two months, had felt a lump in the vagina, and had tried to push it back with a crochet hook, which disappeared She aborted in hospital and at operation the crochet hook was found protruding through the posterior wall of the uterus and firmly embedded against the sacrum It was removed with little difficulty, and she made an uninterrupted recovery

The PRESIDENT inquired whether these cases should be reported to the police

Dr MURRAY said that he had had a case of premature twins in which he suspected criminal abortion He had asked the British Medical Association what should be done and had been advised not to do anything unless the patient died.

Dr J W BRIDE had removed two crochet hooks from the abdomen, one from the right kidney pouch and the other from the pouch of Douglas In neither case was the patient pregnant, though pregnancy was suspected One of the cases was already in the hands of the police, and when he informed them that the patient was not pregnant, they took no further action

Dr CROFT had had a similar case, and had removed the foreign body after the abortion.

Miss RUTH NICHOLSON described a case of cystic papillary tumours of the ovaries

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

AT a recent meeting of this Society, Dr J C BUCKLEY, the President, in the chair, Dr J STANLEY WHITE read a paper entitled

Some Recent Aspects of Gland Therapy

After dealing generally with the subject of hormone balance he went on to speak of the glands individually He laid emphasis upon the value of determining the basal metabolic rate in cases of thyroid dysfunction, and speaking of the use of thyroid in obesity reminded his audience that obesity was not necessarily due to hypothyroidism Obesity was often influenced by gland therapy, but it was obvious that thyroid obesity was really a minor manifestation of myxœdema Other endocrinological aspects of obesity had to be considered—pituitary obesity, thymic obesity, and gonadal obesity Referring to the less severe cases of hypothyroidism, he expressed the opinion that these cases were much more frequent than was generally realised A medical officer of health had stated that sometimes as many as 10 and 12 per cent of children in a community might be exhibiting mild forms of hypothyroidism He instanced the type of patient that became readily fatigued and was not able to apply himself closely to study Such cases responded well to minute doses of thyroid

Going on to speak of exophthalmic goitre Dr White said that until recently Graves's disease had been regarded as a condition of hyperthyroidism, the symptoms being attributed to the presence in the blood of a secretion that was normal in quality but abnormal in quantity The distinction between the excessive secretion of a normal substance and the secretion of an abnormal and toxic substance had only been clearly worked out within the past few years, and we were now compelled to recognise hyperthyroidism as a condition entirely distinct from exophthalmic goitre, and one that called for quite different treatment

The parathyroid glands, said Dr White, were embryologically related to the thymus rather than to the thyroid, although in practice it was found difficult to present a parathyroid product which was entirely free from this latter gland He explained the theories underlying parathyroid therapy, making reference to the Noel Paton school, which regarded the parathyroid as a detoxicating agent in that it seemed to be capable of neutralising the poisonous purin derivative guanidin, which otherwise tended to collect in the muscles Many clinicians, however, favoured the view that the function of the parathyroid was chiefly to control the

DISEASES OF THE EYE

Fifth edition. By SIR JOHN HERBERT PARSONS, C B E , D Sc , F.R.C S , F R S., Ophthalmic Surgeon, University College Hospital , Surgeon, Royal London (Moorfields) Ophthalmic Hospital London J and A Churchill 1926 With 21 plates and 313 text-figures Pp 676 19s

THIS book contains the information that the average student is likely to require without being so bulky as to frighten him The fifth edition does not greatly differ from its predecessors There are 23 extra pages which include 17 extra figures, some of which illustrate the use of the slit-lamp for displaying the intimate structure of the lens or the exact depth of a foreign body in the cornea ; others reproduce some valuable pathological sections by the late George Coats, illustrating the microscopical appearances in vascular diseases of the retina These subjects cannot be more than lightly touched on in a book of this scope The author's views on the pathology of retinitis pigmentosa or of angioid streaks in the retina are not universally acceptable Some operators, again, though not many in this country, might demur at the somewhat cavalier way in which the newer operations for intracapsular extraction of the lens are dealt with, while other authorities might consider too dogmatic the advice given as to the treatment of difficult cases of sympathetic ophthalmia—to excise the wounded eye, even when it retains sight, the moment there is the slightest sign of ciliary irritation or keratitis punctata in the fellow eye But a text-book is no place for the exhaustive discussion of controversial matters The student has to learn some time that opinions on certain parts of ophthalmology are not unanimous, and it is on the whole desirable that he should realise this at an early stage of his career For a practical guide to the subject, however, he has in this book all that he is likely to require before he begins to specialise, and no one could wish for a more concise and readable exposition of the present-day orthodox teaching of ophthalmology

ASTIGMATISM

Die Bestimmung des Astigmatismus durch die Schattenprobe mit Cylinderglasern By Prof Dr K LINDNER, Director of the Eye Clinik in the General Polyclinik of Vienna Berlin S Karger. 1927. With 83 figures, some coloured Pp 111

THIS is a book well worthy of study by that increasing number of students and practitioners who aim at making the accurate determination of refractions an important part of their life work It is easy enough to learn how to do a retinoscopy which shall be approximately accurate, but to attain precision is far more difficult, so much so that for what we may term the fine adjustment, many still prefer to rely chiefly on subjective tests The matter becomes specially important in two classes of patients with astigmatism, first, those who are peculiarly sensitive to minimum degrees or minimum variations of the degree, and, secondly, those in which the axis of the astigmatism is oblique When these two conditions are combined the case presents the maximum amount of difficulty Prof Lindner has specialised in the teaching of retinoscopy, and we know of no book in which the niceties of the method are better explained and illustrated Especially is this true with regard to the determination of the angle in which he makes great use of the "astigmatic band" and the variations in its direction which are produced by a cylindrical glass placed at an angle different from that of the astigmatism For his methods the use of cylindrical glasses for the retinoscopy test is essential, and this will prove a difficulty in hospital clinics where, as a rule, the retinoscopy box contains sphericals only For learners the author strongly recommends an artificial model This book should prove of great value to readers who desire to do the best possible work as refractionists

MOSQUITO REDUCTION AND MALARIAL PREVENTION

BY J A. CRAWFORD, M B , Ch B. Edin , Captain, R A M.C , and B S CHALAM, L R C P. & S. Edin London Humphrey Milford, Oxford University Press 1926 Pp 102. 4s 6d

OF elaborate general treatises on malaria and its prevention there are enough, but these have been for the most part unintelligible to the layman In this book the authors explain in non-technical language the simple facts of practical anti-mosquito work in the field It is designed to be a suitable source of instruction for the manager of a tea estate, a sanitary inspector, or a non-commissioned officer of a regimental sanitary squad, and deserves to be appreciated by these Though this book is intended for those who have to combat the mosquito pest abroad, it may be informative to local authorities at home, to supplement the pamphlet published on this subject by the British Museum, to which the Minister of Health had occasion to refer in the House of Commons on March 1st It is obviously impossible entirely to avoid the use of scientific names, but it would have been better to describe the appearance and habits of larvivorous fish in English rather than to record them in doggerel Latin More attention might have been paid to the illustrations—the line-drawings of the developmental cycle of the mosquito are not very good A synoptical table of the differential characteristics of the Indian anopheline mosquitoes completes a useful work

MODERN CLINICAL SYPHILOLOGY

By JOHN H STOKES, M D , Professor of Dermatology and Syphilology in the School of Medicine, University of Pennsylvania With the cooperation of PAUL A O'LEARY, M D , WILLIAM H. GOECKERMANN, M D , the Mayo Clinic, LODEN W SHAFFER, M D , and CLEVELAND J. WHITE, M D London and Philadelphia W B Saunders Company 1926 With 865 illustrations and text-figures Pp 1144 55s

SO many text-books on syphilis have been produced in recent years, repeating the same facts in very much the same way, that it seems almost impossible that welcome could be found for yet another This book, however, differs from most of its predecessors in important respects, notably in that the reader gets the impression that the authors have had vast experience in the disease The views put forward are essentially those of Prof Stokes himself, while an account of alternative views would often have been useful, we can hardly regret the condensation which has enabled him to produce a readable work in one volume, which is nevertheless unusually complete If we have any fault to find with the book, it is with the presentation on so many pages of differences in symptoms and signs arranged in tabular form This is not an attractive way of setting out information, though it may be justified on the ground that this it saves space The sections dealing with neurosyphilis are outstanding in a work which has unusual merit

HEALTH

Resistance to Disease. a New Orientation Second edition By HARRY MERRALL, M B , Ch B London Williams and Norgate 1927. Pp 181. 6s

DR Merrall is impressed by the fact that the alimentary tract is more or less lined from end to end with lymphoid tissue, and he regards the leucocytes which, he says, are derived from that tissue to be one of the most important defences of the body against microbic invasion He believes also that intestinal toxæmia is the source of many ills and that iodine is an element necessary to salvation. He urges, therefore, that people should keep themselves healthy by seeing to any catarrh, and especially by swabbing the throat with iodine and glycerine, and by keeping their bowels open by belly exercises advantage in mortality in a life-table of parents only, due to the inclusion in the exposed to risk of people before the age at which they became parents—i e, before the age at which death can occur, the second is the selective factor involved in marriage, which again Dr Pearl does not distinguish from parenthood The genealogical material used as illustration suggests that it may consist of socially "better" lives than the general population, which would to some extent outweigh the declining death-rate To go back to the main subject of the book, we may hope that not many people will take seriously Dr Pearl's advice to "learn by precise experimentation what constitutes moderate drinking *for him*" Precise experimentation with one's own individual expectation of life is apt to be dangerous

The book contains a bibliography of some 270 works—a selection from a much larger one which the author hopes to publish later

---

POPULATION PROBLEMS OF THE AGE OF MALTHUS

By G TALBOT GRIFFITHS, B A Cambridge University Press 1926 Pp 276 12*s.* 6*d*

THIS book is a critical and scholarly study of the factors affecting the birth-, marriage- and death-rates prevailing in England and Ireland at the time of Malthus—that is to say, between the years 1766 and 1834. The problems arising from the vital statistics of to-day are not considered, neither does the author draw any inferences bearing upon them from the period he discusses But in spite of this, the book has much more than an academic interest The cultural changes which took place between 1750 and 1850 were responsible for the initiation of that upward leap in the population of these islands which, though steadying itself in the latter years of the nineteenth century and in the present century, has since been maintained, and despite the fall in the birth-rate, is still in operation to-day This fall in the birth-rate, and the behaviour of the birth-rates of other European countries, have in recent years directed much attention to problems of population, which cannot be understood without the historical background which it is the aim of this book to provide. For the task which has here been so painstakingly accomplished, Mr Griffiths will earn the gratitude of the historian, both of economics and medicine.

Our knowledge of the dimensions of the population of Great Britain and Ireland throughout the eighteenth century is, and is likely to remain, incomplete But so far as it goes, it points to a fairly uniform increase in the birth-rate from the figure of 27 5 per 1000 in 1710 to that of 35 4 per 1000 in 1790, after which the rate steadily fell to about 32 per 1000 in 1836, the year of Malthus's death Far more dramatic than anything in the birth-rate, however, are the changes presented by the death-rate during these years The curve of the death-rate seems to have reached a peak of 33 4 per 1000 in the year 1730, when it was actually higher than the birth-rate; and then, except for a rise of 2 per 1000 between 1760 and 1780, to have plunged downwards till the year 1810, when, in the figure of 19 9 per 1000, it reached its lowest point for the indicated period Between 1730 and 1810—a period of 80 years—the birth-rate maintained itself within a margin of 2 per 1000 Between 1780 and 1810—a period of 30 years—the death-rate fell by 9 per 1000. The chief argument of this book is based upon a comparison of these rates, and is to the effect that, discounting immigration from Ireland, the sensational fall in the death-rate during Malthus's life was a more important factor in the increase of the population than was the comparatively small change in the birth-rate The prominence to-day given to the subject of artificial birth control in public discussion—a practice first popularised during this period not by Malthus (the author thinks that Malthus would have been opposed to it) but by Francis Place—has resulted in stress being laid on the birth- rather than the death-rate in causing the increase in population that characterised the period The facts adduced by Mr Griffiths seem to indicate that the stress has been laid upon the less important phenomenon

The various factors affecting the birth-rate by encouraging early marriages and fecundity in marriage—factors chiefly social and economic—are closely examined To medical men, however, the factors recognisable for reducing the death-rate will be of greater interest A chapter of some 50 pages is devoted to an analysis of the influence of increase in medical skill upon the fall in the death-rate Though medical skill can increase the birth-rate by eliminating factors like venereal disease and lead poisoning which diminish the number of births, it is upon reducing the death-rate that it exerts its most important effect During the period here reviewed medical teaching was organised all over Europe, and the foundations of our existing hospital and dispensary systems were laid Through improvements in sanitation and through the realisation—first occurring at this time—of the importance of cleanliness and ventilation, the incidence of fevers was much reduced In the earlier years of the eighteenth century fevers were responsible for one fifth of the annual mortality of London Deaths from puerperal sepsis were also much diminished through the same agencies But from the social point of view, perhaps, the most important event of all was the lowering of the infantile mortality-rate This seems to have been in large measure brought about by better feeding, the improved supply of milk and of fresh vitamin-containing foods being due to advances in agriculture and cattle farming which occurred at this time And not least important, epidemics of small-pox, which, throughout the eighteenth century had taken an enormous toll, especially of children, were much mitigated in severity by the introduction of vaccination

This book is a valuable piece of research into a phase of our recent past which the historian of the future will probably regard as critical in the development of the present age

---

TRADE DERMATITIS

Schädigungen der Haut durch Beruf und gewerbliche Arbeit By K ULLMANN, in collaboration with M OPPENHEIM and J H RILLE Vol III., Sections 1–2 and 3–6, in two paper-covered volumes with articles by numerous writers and many half-tone illustrations in the text Leipzig L Voss 1925–26 Sections 1–2, pp 96, Sections 3–6, pp 308

THE increasing economic importance of industrial disease has created a general demand for statistical and other data The scope of these volumes is by no means limited to the suggestions conveyed in the title, and although skin affections occupy the major space, there are articles by various experts of interest to ophthalmic and dental surgeons, to factory inspectors, and medical assessors. Research workers will find some valuable information in the studies included in the paper on "cancer as a sequel" in industrial disease. This article is profusely illustrated and well furnished with a bibliography, and is an important contribution to a question much studied at the moment An article on prophylaxis is well conceived, and is followed by a summary of the regulations (German and foreign) which have been drawn up from time to time with that end in view There is a short dissertation on treatment

The classification of the various articles appears to be somewhat haphazard, and there is no evidence of a guiding hand or plan in their selection The work as a whole must be regarded rather as a compilation than a text-book, and an introductory paper or editorial preface would greatly improve a future edition.

THE LANCET.

LONDON: SATURDAY, MARCH 19, 1927

CHEMICALS IN BREAD

THE Departmental Committee on the Treatment of Flour with Chemical Substances has now presented its Report [1] The Committee was appointed in July, 1923, to inquire into the use of preservatives and colouring matters in food, and the final report on this general inquiry has already appeared[2], but in June, 1924, the reference was extended to include the question whether and to what extent the practice of treating flour with chemical substances is objectionable on grounds of health and whether it is desirable in the interests of the public health that the practice should be prohibited or restricted, and in the latter case what restrictions should be imposed—and the present Report deals exclusively with the supplemental reference This inquiry has been long and difficult A considerable part of it was necessarily of a technical character, commercial considerations have intervened in large measure, and the question has involved applied chemistry in a field where exact knowledge is difficult to come by and accurate deduction still more difficult to make The Bread Acts of 1822 and 1836 made it a legal offence to sell bread containing—apart from its essential cereal content—any ingredient other than common salt, pure water, eggs, milk, barm, leaven, potato or other yeast, and the Food and Drugs Act of 1875 penalised the addition to an article of food of any ingredient so as to render that article injurious to health, but there was a proviso in this Act permitting the addition of something, not in itself injurious to health, though required for the production or preparation of the food in a state fit for carriage or onsumption, and finally an amending Act of 1922 sanctioned the addition of any ingredient for the purpose of making flour self-raising, subject to the power of the Minister of Health to prohibit or restrict a particular ingredient Conformably to these legal provisions there has grown up during the last 20 years a widespread practice in this country of introducing chemical substances into flour for the purpose of bleaching or improving it The practice of bleaching arose, it appears, in response to the large demand amongst industrial and manual workers in the north of England and in Ireland for a specially white flour, a demand which would otherwise have resulted in disastrous competition from the naturally bleached commodity offered by the flour importers This type of addition may fairly be regarded as eyewash, being directed simply to the production of an appearance and not of a quality, but in regard to the so-called mprovers the milling industry claims for them an nhancement of the natural baking qualities of the lour so as to yield what is regarded as a good loaf Not all flours are capable of producing a loaf which rises well, is of a satisfactory texture, evenly aerated without large cavities or heavy streaks, and with thin, smooth, crisp, unbroken crust Millers claim that the deficiency of any flour in the qualities necessary for making a good loaf can be remedied by appropriate chemical treatment, with the result—as was recently set out in our own columns [3]—that people are supplied with a pure loaf of better flavour and greater digestibility and consequently higher nutritive value

The number of chemical substances at present in use is quite small, the list comprising little more than nitrogen or benzoyl peroxide for bleaching, acid calcium or ammonium phosphate and persulphates for improving, and chlorine or nitrogen trichloride for the dual purpose, known commonly as maturing The present Report takes as read a report presented to the Local Government Board 15 years ago by Dr HAMILL (which described in detail the structure of grain and flour and the processes of modern milling) and devotes its attention to the improvement of flour by chemical means, a practically new field now being developed by cereal chemists on the scientific as well as on the empirical side The Millers' Association have as the result of laboratory investigation developed widely the practice of building up blends of flour in which one unit makes good the defects of another, the chemical improver being brought in finally to correct any defect found in the baking test applied to the composite flour The hydrogen-ion concentration of the top grades of flour is greater than that of the lower grades and the improving, stated in chemical terms, may be a result of bringing this concentration to the appropriate level of about pH 5 5, associated probably with some oxidation of the gluten which there is good reason to believe occurs in two distinct forms The Committee does not doubt that the use of improvers has been a valuable aid to home millers in competition with overseas supplies, and their employment enables the miller to use any supply of sound wheat available, taking advantage of whatever comes to hand and producing a standard flour at the lowest prices This, it is admitted, may result in the more extended use of what millers call inferior wheats, although it should be understood that this commercial inferiority does not imply a lesser nutritive value Bleaching affords the miller the opportunity of eliminating the difference between higher and lower grades of flour from the same wheat, so that by appropriate treatment flour which would otherwise have to be sold as "household" can be lifted into the "patent" grade

After thus clearing the ground the final section of the Report deals with the health of the consumer, which was the avowed object of the inquiry It has been notoriously difficult to demonstrate that the addition of minimal quantities of a foreign ingredient to any staple article of diet is deleterious, and precisely for this reason a Government amendment has just been introduced at the Committee stage of the Sale of Food and Drugs Bill now before the House of Commons, the purpose of which is to save local authorities from having to prove in any particular instance that the presence of a forbidden preservative, or the excessive amount of a restricted preservative, is injurious to health The view of the Departmental Committee, frankly stated in so many words, is that flour should be a product of the milling of wheat, without the addition of any foreign substance, but after stating this principle they were confronted at once with the difficulty that to insist upon it would be to waste supplies of wheat and to raise the price of flour So long as a great demand exists for very white breads, they admit that some form of bleaching process must be permitted Whatever may have been alleged to the contrary, the Committee regards the majority

[1] The members of the Committee were Sir H C Munro hairman), Prof W E Dixon, Sir A D Hall, Dr J M Hamill, r O Hehner F I C (replaced later by Mr P A Ellis Richards, I C), Prof F G Hopkins, Dr G R Leighton, Dr A P Luff, r C Porter, Mr G Stubbs, F I C, with Mr A M Legge, ecretary. Ministry of Health, 1927, H.M. Stationery Office, 6*d*

[2] THE LANCET, 1924, ii, 929.

[3] THE LANCET, 1920, ii, 1038

His advice has evidently proved so attractive that this revised, enlarged, and cheaper edition of his book appears two years after the original version It is difficult to understand why he should begin with such a proposition as "our conception of the occurrence and development of disease is in the main erroneous," and why he should call his book "a new orientation " It is a pity, too, that his good, practical suggestions should be backed up with a physiology and pathology which are too often questionable. But we can well imagine that there is a common type of lay reader to whom he will appeal with much success and improvement in healthiness, and, since other opinions are to be had in times of trouble, he is not likely to lead anyone very far astray

---

RADIOTHERAPY

La Roentgentherapie des Epitheliomas Cutanes et Cutaneomuqueux By Dr GEORGE GIREL Paris Masson et Cie. 1926 Pp. 301. *5s*

THIS book gives a detailed account of the methods evolved by Dr J Cost, of Lyon, for the radiotherapeutic treatment of malignant diseases of the skin This method, as distinct from those usually employed, may be summarised as the use of rays of medium wave length, unfiltered and in massive doses given at a single application An average dosage would be 25-30 H in a single sitting, using a 6½ in gap, no filter, at a distance of 22 cm with 2 ma going through the tube This dosage produces, the author states, a "radio-epidermite " as distinguished from a "radio-dermite " or reaction of the third degree followed by ulceration and necrosis He claims 98 per cent of success, and complete cicatrisation in about one or two *months after the date of treatment* A long list of cases is given in detail, from which it appears that some burns were produced This, *however, is attributed to a particular tube* which was old Pilon, ordinary and 30 ma Coolidge tubes were used The method seems to us drastic, and the risk of serious X ray burns unduly great ; no doubt in the hands of its formulator it is successful

In the second part of the book practical details are given to show that the method can be carried on with the simplest of apparatus The remaining space is devoted to a histological study of the tumours treated and to their classification

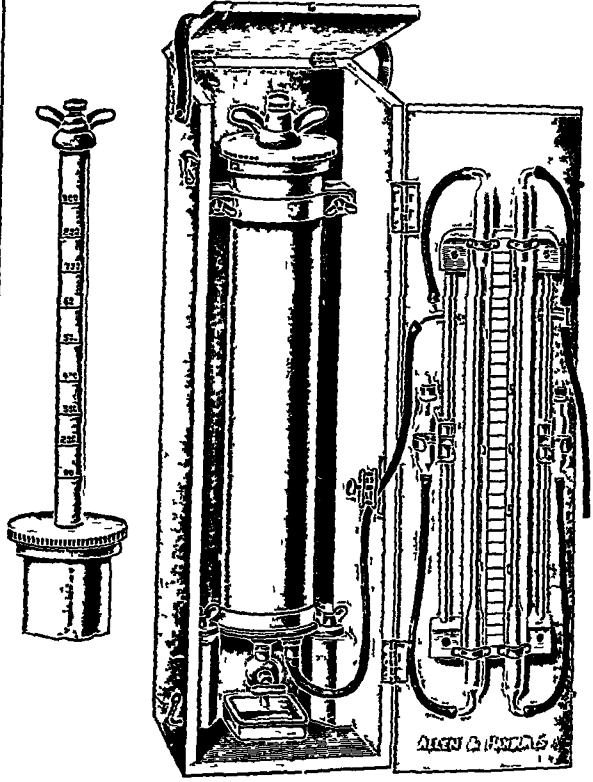
AN IMPROVED PNEUMOTHORAX APPARATUS

THIS *artificial pneumothorax apparatus was* suggested and designed for me by Miss V Holmes, B Sc (London), to overcome two of the shortcomings *of existing instruments—namely, fragility* and the necessity for manipulation during the operation to maintain a constant flow of air at even pressure

The ·apparatus consists of a carefully ground brass cylinder topped with a flat cap The lower end is filled with a sump in the shape of an inverted cone, with a stop-cock at the extreme *lowest point, and a nippled opening* at a slightly higher level The cylinder is fitted with a hollow brass piston, to which is mounted a hollow piston rod whose lumen *is continuous* with that of the hollow piston The piston has circular grooves, and from the bottom of these grooves holes are bored through to its central chamber The top end of the piston rod is fitted with a simple device for locking it to the cylinder top when the piston is at the bottom of its stroke, and also with a knurled screw to seal the open end The piston chamber is filled with castor oil via the piston rod, *and this oil flows* into the piston grooves through the holes mentioned above This gives a perfect airtight fit, and at the same time permits the *piston to fall* smoothly but quickly by its own weight The cubic content of the cylinder is about 700 c cm and the piston rod is graduated to show the cubic content of air at atmospheric pressure at any position of the piston From the nippled opening in the sump a rubber tube runs to a metal tube in the box lid, which metal tube has two side openings connected by rubber tubes with the manometers A further rubber tube passes from the metal tube to the patient The flow of air between the cylinder and the metal tube in the lid is controlled by a simple screw clamp

To operate the screw clamp is closed The stop cock *in the sump is opened* (any excess of castor oil in the sump will then drain out) and the piston is raised to the top of the cylinder , the stop-cock is closed, and the piston allowed to settle, compressing the *enclosed air* The pressure exerted by the piston is equal to about 50 cm of water The rubber tube leading to the patient is fitted with a needle and introduced , the screw clamp is released until it is seen *from the movements of the piston rod that air is flowing* at the desired pace The pressure at the needle point varies with the rate of flow, and can be set at any pressure from ¼ cm of water to the full capacity of the manometers, according to the amount the screw clamp has been released The quantity of air used can be read from the piston rod graduations



Any form of manometer can be used The one illustrated is a copy of that used on Dr Parry Morgan's old apparatus The manometer nearest the cylinder is filled with a mixture *of oil and chloroform of sp gr* 1000, the one nearest the patient with coloured water During the operation, the water manometer fluctuates freely with the patient's respiration, showing the pressure at the needle point The oil manometer scarcely fluctuates with respiration, and before the screw clamp is opened is set to the patient's mean intrapleural pressure, and continues to show this throughout the operation, provided *that* the oil used is not too viscid and the air is not introduced *too* rapidly If another clamp is introduced on the rubber tube between the cylinder and the *screw clamp*, and a needle is fitted at the patient's end, the screw clamp can be so adjusted that any pressure can be maintained at the needle point , the second clamp can then be used for starting and finishing the operation This method is useful for induction, as it allows the gas flow to be controlled instantaneously, or when a series of refills are to be done, as it saves the time needed for constant *readjustment of* the screw clamp

If the instrument is used as illustrated, it is unnecessary to touch it at all during the operation, except *to* open the screw *clamp at* the start, and to close it when sufficient air has been introduced, and the operation need not be interrupted for pressure readings, as the mean *intrapleural* pressure at any moment is visible on the oil manometer

The instrument has been made for me by Messrs Allen and Hanburys, Ltd , *Wigmore-street*, London, W.

crepancies in the incidence of nervous and venereal diseases being accounted for probably by differences in nomenclature

We note that the report appears to lay the responsibility upon the medical profession for the proper distribution of practitioners, but it seems to us that this is a matter in which the public should take the initiative Throughout the United States the growth of population in the towns in comparison with that on the countryside—a position the embarrassments of which we know very well in this country—has led to the fact that there are many localities which are not properly staffed by medical men as well as devoid of institutional and nursing amenities Notably it is the older doctors who resort to or who remain in the country, a fact which had been elicited by Dr W A PUSEY in a study of 283 rural counties in 41 States, which he published in the *Journal of the American Medical Association* This investigation indicated the average age of physicians practising in these country districts to be 52 years, and the average period which they remained in practice to be 26 years This study brought out further that only 9 per cent of the 4410 physicians practising in these counties were graduates of the last ten years, and that no recent graduate had gone into 35 per cent of these counties during the same period A recent study of conditions in the State of Michigan showed that in 1925 the largest number of physicians at any one age was in the period of 50 to 54 years, whereas in 1914 the largest number of any one age was in the period of 35 to 39 years The figures are revealing as to the position in the vast Transatlantic countries, in Great Britain it is only faintly reflected, as only in a few areas does country practice mean the extreme isolation indicated in Dr PUSEY's inquiry There is reason to think that with us the position, so far as it existed, is righting itself under the National Insurance Act

THE MANAGEMENT OF PNEUMONIC PLAGUE EPIDEMICS

WHATEVER Government rules China that country must long be a source of anxiety, from the sanitary point of view, because North Manchuria still harbours the Siberian marmot or tarbagan, an animal peculiarly susceptible to natural infection by plague The pneumonic plague epidemics of North China can all be traced back to this small rodent and to the hunters who trap it for fur In the great Manchurian outbreak of 1910–11 Dr. Wu Lien-Teh (better known in Europe as Dr. W L Tuck) played a memorable part, and the lessened severity of the two later epidemics was due largely to the combative measures adopted and directed by him, and to the standing anti-plague organisation whose inception and maintenance owe so much to his efforts Pneumonic plague is not confined to North China; it is perhaps even more rampant now than in the past, and Dr. Tuck's latest contribution[1] *to the literature* is welcome It is the fruit of an unrivalled experience of three great epidemics and of a thorough exploration of what is already on record The result is an authoritative work It is dedicated to the known and unknown who have sacrificed their lives fighting or investigating pneumonic plague, and in the last 14 years most of these must have fallen actually by the side of Dr Tuck

Not rarely pneumonic plague has been frequent in newly invaded areas, but has later become inconspicuous in the same foci, this was noticed, for example, during the Black Death pandemic It is by no means clear how an outbreak starts Racial susceptibilities cannot play any important rôle, but climatic conditions may enhance the susceptibility of the lungs, aggravate the bad social conditions which impair individual resistance, and by leading to overcrowding, increase the chances of contagion There may even be a special character in the epizootic The nature of the epidemic itself is determined by a chain of circumstances, perhaps peculiar to each locality and community Although it is true that an outbreak of plague pneumonia may, of its own accord, decline and disappear, this is no excuse for neglecting stringent measures to suppress it Treatment is difficult, for the infection is one which, in its selection of the lung for primary attack, is too rapid and severe for any remedy yet discovered, in the overwhelming majority of cases of manifest plague pneumonia immune serum has failed to be of benefit In view of the difficulties, an epidemic must be fought not by one invariable scheme, but by a combination of methods adapted to the locality, the season, and the particular traits of the afflicted populace. For personal prophylaxis the best measure is the wearing of a protective mask Its use dates back to 1348 and the Black Death in Europe, at which time it evidently became widely known that infection was directly transmitted through the air. In the three Manchurian epidemics a mask of absorbent cotton-wool, tied over mouth and nose by a many-tailed gauze bandage, was evidently efficacious, it is probably impervious to cough droplets, though tests have proved that it lets through the smaller drop obtained by artificial spraying A hood of heavy flannel cloth tied at the neck and fitted with mica window withstands far severer tests and is not more inconvenient or uncomfortable than the gauze cotton-wool mask Everyone in any epidemic area is obliged to avail himself of this protection all the time, whatever the duty or common task What more obvious or safer insurance can there be against a coughing neighbour? The occurrence of many laboratory fatalities imposes it even on the secluded pathologist staff. Personal protection by immune serum, or plague vaccine, or both, is less certain, though these measures undoubtedly lengthen the incubation period At least 100 c cm of the serum must be injected as soon as possible after exposure to infection, and this dose will confer some passive immunity for possibly as long as two weeks Thousands of people may need injection and the cost of serum is high Experimental data, says Dr Tuck, are but little in favour of vaccine In natural circumstances, however, the infective dose is rarely so massive as that given by inhalation to animals in experiments, and in the pneumonic epidemics plague vaccine seems to have given better results than might have been expected on theoretical and experimental evidence It is not to be discarded in spite of the grim fact that in epidemics some of the fully vaccinated sanitary personnel have succumbed to plague pneumonia

General prophylactic measures are, at best, only palliative Pneumonic plague is secondary to human bubonic plague, which in turn arises from plague in rodents, and the preventive measures should ideally be directed against these two precedent infections The different branches of the anti-plague organisation should, in Dr Tuck's opinion, be directed by a single chief medical officer The coöperation of medical practitioners is readily obtained, whilst that of the population has to be sought by educational measures Cases must be detected promptly—which means house-to-house inspection—and isolated in hospitals or camps Contacts must be placed under strict medical inspection in segregation quarters for at least seven days, or for ten days if they have been vaccinated or protected with serum, so that the incubation period may be prolonged It is a natural instinct to flee from plague-ridden localities and flight has been recommended from Biblical times; Cardinal Wolsey followed his own advice for time of plague—to change quickly to fresh and purer of added substances as foreign to flour, for the phosphorus and sulphur found in the ash of untreated flour do not seem to be present in the form of phosphates or sulphates *in the flour itself* They suggest that chlorine, besides combining with carotin to form a colourless addition compound, does also combine to some extent with the oil of flour and may in so doing injure the nutritive value of the gluten by the entrance of chlorine into the tyrosin and tryptophane groupings Direct experiments of feeding rats on flour treated with chlorine or nitrogen trichloride were inconclusive, but judging by all the evidence before them they regard both chlorine, whether free or combined with nitrogen, and benzoyl peroxide as undesirable additions to flour They are not prepared to recommend the complete elimination of the bleaching agents and improvers now in use, but they think it should be made conpulsory on manufacturers to declare to purchasers the precise ingredients of their wares, and equally compulsory on millers to inform their customers whether their flour has undergone a process of chemical bleaching or improving or both, and if so with what substances and in what proportions There are bakers, the Committee state, who wish to know the nature of the materials they are using, and who want flour, and not a mixture of flour with something else Finally, they welcome the possibility shown in their inquiry of improving flour by physical rather than chemical methods, and are impressed by the success which has already attended these experiments on a commercial scale Before proposing these very modest limitations on the liberty of the miller to add to flour what chemical substances he will, the Committee had ascertained that in Australia and New Zealand the artificial bleaching of flour is prohibited and bread may not contain any foreign mineral substance other than common salt Switzerland also forbids bleaching Canada has, however, recently recognised the practice of bleaching with a minimal amount of nitrogen peroxide if so stated when the flour is sold, and the United States of America, as well as Switzerland, have sanctioned the addition of limited amounts of unobjectionable salts serving solely as yeast nutrients The Report is now open for the consideration of a public, every member of which consumes bread in larger or smaller degree, and is affected in mind, body, or estate by the practices which the Committee was appointed to investigate

MEDICAL EDUCATION IN THE U S A.

MEDICAL education in the United States of America is regulated largely by the specifications and rules of several different agencies, one among which, the Association of American Medical Schools, has devoted itself particularly to the problems of the ideal curriculum and to the inspection of medical schools A committee of the Association in 1925 called together a group of persons representing general and scientific education, the medical profession, and the related sanitary interests, and organised a Commission on medical education That body has now issued a report, derived from a preliminary study of some of the general questions which have been considered, promising that, as more material is assembled and other studies made, additional reports will be published The first document is so practical that its sequels will be looked for, and the medical schools having part in the Association, as well as the Rockefeller Foundation, the Carnegie Corporation, and the American Medical Association, may be congratulated on finding the financial support for such useful endeavour The initial stage of the labours could not have been easy, for the Commission in certain directions pre supposed an inspection of medical schools, and not only of the examinations instituted by the various qualifying bodies, and to bring schools up to a certain level may be harder than to evaluate their respective efforts by criticism of the different methods of testing Further, the local adaptabilities for medical practice in the United States have to be borne in mind, for, despite similarities of pattern that may exist in many localities, each State has developed its own requirements, which have exerted a considerable influence both on the domestic details of the curriculum and on the legal status of the schools

The report commences by a shrewd definition of the proper objective of medical study and a fair summary of this section would be as follows The medical training given to the student should be sufficiently broad, while perfectly sound, to serve as the groundwork for subsequent development, it should provide students with the training needed for competence to begin practice, while preparing them also to make general or special use of their developing clinical insight and experience The sections of the document dealing with the various circumstances which determine the chances presented to the medical profession of doing their work in the most efficient way and for the good of the public, follow lines which are familiar to all who have studied analogous problems in this country, but the action of the Commission here has been thoroughly practical To obtain information on the demands for medical services, the coöperation was enlisted of 500 recent medical graduates practising in communities of 50,000 or less in a group of 24 States and two Provinces A study of the activities of these men has revealed that 90 per cent of the cases requiring treatment could be adequately cared for by the practitioner who had received the medical training that is provided in those States through the medical licensing boards The patients presented themselves in the rough numerical proportion of 55 per cent at the doctor's residence, 35 per cent were domiciliary visits, and 10 per cent institutional cases As might be expected, three-quarters of the cases visiting the doctor had minor surgical injuries, while the domiciliary visits were in respect mainly of infections of the respiratory tract, medical conditions, zymotics, and obstetric patients, only 10 per cent falling under more special designations Further light is thrown on the health needs of the American population by an analysis of the defects found through recruiting statistics A report of the Surgeon-General of the United States Army has analysed the records of 2,750,000 of those men, they reveal that 46 per cent had defects of one sort or another A more detailed analysis of this enormous figure would show, of course, that many persons categorised as "having defects," would exhibit no immediate need of medical attention, while in many the time would have gone by for fruitful treatment But even so, the residue will be very large, and the Army figures confirm the necessity existent in the States for many doctors properly standardised and properly distributed An interesting comparison is made in the report with medical practice in Great Britain, for the demands on American and Canadian practitioners are contrasted with a survey of the causes of illness which led persons to consult practitioners under the National Insurance Act, as set out in a recent report of Sir GEORGE NEWMAN The British, American, and Canadian figures have close general resemblance, the dis to see binocularly is sufficient to prevent the child from squinting; but if the fusion-sense is absent or badly developed, the mechanism which coördinates the lateral eye-muscles may easily be thrown out of gear As most children are hypermetropic the squint is generally convergent, but it may be divergent. In either case when a squint is well established the attention of the child is so concentrated on the image in the better eye that the one formed in the retina of the worse eye is not attended to at all. It is "suppressed," and if this suppression is allowed to continue the eye often becomes incapable of any useful vision. It is this fact that renders it so essential that all squints in children which are constant should be treated without delay—not by operation in the first place at any rate. but by glasses and if necessary by forcibly suppressing the image not of the squinting eye but of its fellow If one eye is blind from infancy it may or may not squint If it does the squint is generally convergent at first. but in later life may become divergent Similarly, if both eyes are blind from infancy they may or may not squint, but in this case the reflex stimulus to the coördinating mechanism having never been in action the latter is so far put out of gear that there is almost always nystagmus If. on the other hand, as in those who become blind after early childhood, the coördinating mechanism has once been firmly established. it almost always continues to function, even in the absence of the sight of either eye Cases of optic atrophy seldom either squint or have nystagmus In myopia a squint is usually divergent but as myopia is almost never present in infancy this is only seen in adults as a rule A single blind eye, whether myopic or not. often diverges in adult life, but in children will as often be found to converge

THE ÆTIOLOGY OF ADDISONIAN ANÆMIA

IT is well over 30 years since Herter postulated a relationship between the abnormal activities of *Bacillus welchii* in the large intestine and the occurrence of pernicious or Addisonian anæmia So completely has his work fallen into oblivion that in recent and authoritative English and German text-books on diseases of the blood no mention of the theory is to be found · and in this country at any rate, the presence of hæmolytic streptococci in the duodenum attracts a large share of the attention of those who look upon the disease as an infection. The work of Cornell[1] in Canada, published two years ago, indicated an attempt to rehabilitate Welch's bacillus as the only source and begetter of Addisonian anæmia and have inspired efforts by several other investigators to establish a relationship Thus Moench, Kahn, and Torry[2] have shown that *B. welchii* are present in the intestines of sufferers from the disease in larger numbers than in those of normal persons and by injecting into monkeys small quantities of toxin derived from the bacillus, Kahn and Torry[3] were able to produce a blood picture closely resembling that of Addisonian anæmia.

Following the lead of Cornell, who showed that it is possible to establish a chronic *B. welchii* infection in rabbits, Reed, Orr and Burleigh[4] working at Queen's University, Kingston, Canada, have observed the blood changes produced by the activity of this organism in the tissues of the host By using cultures kept for five to ten days in the ice-chest, and injected hypodermically or intramuscularly into rabbits, they found that they were able to produce local lesions from which complete recovery frequently took place The inception of the infective process was characterised by constant and well-marked changes in the blood picture The notable change was a gross anæmia in which the red cells might fall as low as 1.400,000 per c mm, and as this was not accompanied by a corresponding decrease in hæmoglobin the colour-index was relatively high. Some poikilocytosis was also observed, and a high degree of anisocytosis Averages were taken of the size of the red cells, and curves were plotted showing the relative distribution of cells of various sizes These curves differed grossly from those found in normal rabbits and approximated in their shape to the curves shown by Price Jones[5] to be characteristic of Addisonian anæmia Films of blood from the infected rabbits further showed nucleated forms many of which resembled the megaloblasts which are usually regarded as one of the most typical features of the blood picture in human pernicious anæmia This however, is the full extent of the resemblance between the blood of the infected rabbits and that found in the disease and the rabbits showed a leucocytosis instead of the leucopenia which might have been expected As no differential counts are recorded it is impossible to say whether they had a relative lymphocytosis

These various investigations seem to show that in experimental animals the toxin of *B. welchii* can be made to produce a blood picture characterised by a high colour-index, and a Price Jones curve resembling that of Addisonian anæmia This, however, is far from proving that *B welchii* is the cause of the disease. The term ' Addisonian anæmia " in the present state of our knowledge merely denotes a symptom complex which may have many causes It is recognised. for instance, that infestation by *Bothriocephalus latus* will give rise to the characteristic blood picture, but this does not mean that all patients having this blood picture are suffering from such infestation, and the same holds true for Welch's bacillus None the less, this is a matter which will obviously repay further investigation In view of the well-known fact that anæmia due to hæmorrhage will produce alteration in the size of the red cells in rabbits, it is probably desirable that such work should be conducted on some other animal, and since highly potent preparations both of *B welchii* toxin and antitoxin are now readily obtainable, no advantage is any longer likely to be gained by injection of the living organism.

A BELGIAN HEALTH DEMONSTRATION.

THE idea of health demonstrations originated in America where the best-known, the Framingham Antituberculosis Demonstration consisted of an intensive public health campaign within a limited area aimed at the improvement of public health and especially at the reduction of the tuberculosis mortality-rate From the specialised demonstration America has passed on to the general public health demonstration, and at the present time the Milbank Foundation, with some millions of dollars at its disposal is directing three simultaneous demonstrations—one in a rural area one in a small manufacturing town and one in a New York district. Such demonstrations, although their primary object is educational, are also of the greatest interest from the experimental point of view, for the demonstration area becomes, as it were, a laboratory of applied public health. and the research work carried on is likely to yield data which might otherwise take years to collect It was inevitable that the health demonstration idea should. sooner or later, penetrate to Europe. To the Belgian Red Cross belongs the honour of having staged the first European demonstration, and the report just published of the Jumet Health Demonstration[6] has thus a pioneer interest. Jumet is a small industrial town between Brussels and Charleroi with 30,000 inhabitants. The demonstration which is still in progress was undertaken in 1923 by the Belgian Red Cross in coöperation with the League of Red Cross Societies, and with the hearty support of the local authorities and of the national air. Evacuation of the people is nowadays done to remove them from insanitary and overcrowded dwellings and bring them to camps where better hygienic conditions can be arranged, and where medical inspection can be carried out as though all of them are contacts. Experience has fully confirmed the value of these measures; properly conducted, they have always led to a quick decline of the epidemic. Churches, schools, and theatres must be closed. Cordons within the affected area to limit infection to that area may assist, but the plan of shutting up patients or contacts, or both, within their own houses is too cruel to deserve a place among modern methods of prevention. It is of interest to recall, however, that in 1348 the Pope and his household escaped the Black Death by closing themselves up in the Palace at Avignon. Disinfection should be carried out with discretion and common sense, for little remains to disinfect once the coughing patient, the main source of infection, has been removed. Dead bodies should be cremated, for they teem with plague bacilli, and these in suitable climatic conditions retain life and virulence for long periods. Pneumonic plague spreads not only creepingly from house to house, but also by jumps; someone from a stricken community while incubating plague may travel to a distant place and there cough in a neighbour's face. An efficient cordon should prevent this kind of spread, but some control of traffic from the infected area has to be instituted. It is clear that the methods now available for the suppression of the disease do not guarantee its speedy disappearance. A more timely and universal detection will prevent widespread epidemics, and must be relied on until such time as bubonic plague and rodent epizootics can be eradicated.

"Ne quid nimis"

THE REFUTATION OF A SCARE

It appears that wide circulation is being given in America to statements likely to give rise to the belief or the fear that vaccination against small-pox may cause syphilis. There is available in the public services a mass of direct evidence in refutation of this idea, and the three Directors-General have considered it their duty to issue a public statement that syphilisation as a result of vaccination does not occur. In the days of arm-to-arm vaccination cases of syphilis following inoculation with human vaccine did occasionally arise, although extremely rarely. Syphilis, however, being confined in nature to the human species alone, the possibility of its transference by vaccination was entirely done away with as soon as the use of calf vaccine became universal. Since 1917 the United States Army has vaccinated approximately 4,700,000 members of its personnel, the United States Navy has vaccinated approximately 950,000 of its personnel; and of these 5,650,000 persons not one developed syphilis as a result of vaccination. In not one of them was there ever any suspicion of syphilis in connexion with vaccination. During this same period the United States Public Health Service vaccinated 2,918,748 persons in carrying out its quarantine, immigration, and hospital work. While the Service has not always had the opportunity of following up these vaccinations, as is carefully done in the Army and Navy, no one has ever alleged that any particular individual vaccinated by the Public Health Service has contracted syphilis as a result of vaccination. During the past ten years more than 2,000,000 persons, including school-children, have been vaccinated by State and local health authorities in cooperation with the United States Public Health Service, making a grand total of 10,568,748 vaccinations recorded by the Government medical services, and not one of the undersigned has ever received an allegation or a statement charging that any particular individual of this number has contracted syphilis as a result of vaccination. In fact, there has never been reported anywhere a case of syphilis attributable to vaccination following the use of bovine small-pox vaccine.

Small-pox vaccine is a standard medicinal product, the quality of which is prescribed by the United States Pharmacopœia, and as such is subject to the provisions of the Pure Food and Drugs Law. Furthermore small-pox vaccine, together with other vaccines and serums for human use, has been deemed of such importance by the Government that its production for sale within the jurisdiction of the United States has been under the special protection of an Act passed July 1st, 1902, antedating even the Pure Food and Drugs Law. Under this law all establishments producing small-pox vaccine for inter-State sale must be licensed by the Secretary of the Treasury upon the recommendation of the United States Public Health Service, and the production is controlled by regulations drawn up by a board composed of the undersigned. These regulations provide for repeated inspections of the producing laboratories, for proper labelling, and for all safeguards which may be thrown about the making of such an important product. At present even the placing of the vaccine in the small tubes and the sealing of these tubes is required to be done in such a way that no hand, even though sterile, touches the vaccine. Repeated examinations of the product, for safety, are required. This vaccine it is stated, was used in the vaccination of the millions mentioned, and is exactly the same as that used by doctors in private practice in the vaccination of the general public throughout the United States. The statement is signed by M. W. Ireland, for the U.S. Army, E. R. Stitt, for the U.S. Navy, and H. S. Cumming, for the U.S. Public Health Service.

SQUINT

It has been said that no baby is born with a squint, and this is roughly true, inasmuch as in the absence of either a deformity of the skull or an anatomical malformation of the eye-muscles—both very rare conditions—the visual axes of the two eyes are always approximately parallel at birth. The cerebral centres for the coordination of movement of the two eyes are sufficiently developed to keep them approximately parallel, as a rule, but during the first few weeks or months of life this approximation is by no means exact, and young infants are frequently noticed to squint occasionally, a circumstance that need cause no anxiety unless it persists. During this period the infant is literally learning to see. If the visual axes of the two eyes are not directed towards the same point of any object—say a rattle—it appears double, but the infant soon learns by the sense of touch that he has only one rattle, not two, and by instinct brings the muscles of his eyes to confirm what his hands have told him. The power of binocular vision, however, is as yet far from being fully acquired. The images of any object towards which the two eyes are directed are slightly different because they are formed at different angles. The power of combining these two images into a perception of the object is known as the fusion-sense and it takes years to acquire. Some children, and particularly members of some families, never acquire it, and in its absence various factors sometimes combine to cause a squint. The close association between convergence and accommodation is the best known of these factors, so that hypermetropic children whose fusion-sense is defective are peculiarly liable to it. Not all squinters are hypermetropic, however, and another frequent factor in the causation of squint, of at any rate equal importance, is an unusual call on the nervous system such as a sudden fright or an attack of measles. If the fusion-sense is already well developed the unconscious effort as if the principles underlying the most important of the recommendations of that Commission have never been accepted. Detention, such as is available for the dangerous paranoiac is necessary also for the dangerous and criminal defective; certification too, has its value in dealing with the neglected the abandoned and the cruelly treated: but it is unfortunate that these methods should be considered suitable also for the greater number of aments in need of institutional treatment who do not fall within these categories, for mentally defective children leaving school and the helpless and harmless offspring of poor but well-intentioned and conscientious parents. The humane public is unwilling to look upon mental deficiency as a crime. They have got beyond such views. But if experts appear to maintain that the first requisite in dealing with this serious medical condition is the goodwill of a magistrate the old impression is produced, with the unfortunate suggestion that no more hopeful ideals can be followed.

SUDDEN DEATH AMONG CONSCRIPTS

SUDDEN deaths at the extremes of life when the subjects are very feeble or frail are not so uncommon as to cause surprise but the sudden deaths of men in the army in peace time men of military age men accepted and retained as fit for service these painfully surprise and shock their associates and their relatives awaken suspicions of carelessness and often cause the medical officers of the units concerned anxious searchings of heart. Each such case occurring in the French Army in a regiment and not in hospital is made the subject of a special report. and it occurred to Major X M Cristau that a discussion of the 145 of these reports received in the last seven years (1919-25) might be of use. and might even lessen their number in future. His paper appears in the *Archives de Médecine Militaires* (vol lxxxv p 455). Cases of sudden death fall he tells us into four groups first. those of patients in hospitals whose diseases develop unexpectedly; second. those of men whose complaints during life have been slight or vague: third those of men who have made no complaint in life. but the cause of whose death is discovered at the post-mortem examination. and last. those of patients who made no complaint in life and in whom examination of the body after death has failed to disclose a cause. Some of them (38) occurred in barrack infirmaries or when the men were thought so little ill that they had been left merely "on the sick list." Thus a patient had been a week under treatment for inflammation round an erupting wisdom tooth and was recovering when œdema of the larynx set in and he suddenly died. Ninety of the deaths happened when the men were on duty on leave or in their barrack-rooms asleep without disturbing the men beside them. Thus a Malagasy. on guard did one tour of sentry-go but when he was being called for his next he was found to be dead (of double pneumonia); another of that unit died similarly. but in in his barrack-room. a week later. Such cases should be examined after death but in 40 of those reported. autopsy was refused on account of religious scruple or objection on the part of relatives. Infectious fevers. either in the stage of invasion or by complication caused 31 deaths, 18 due to pneumonia, including 4 of acute œdema. typhoid caused 6. one fatal by hæmorrhage, meningitis 3 2 being tuberculous and of the malarial cases 2 were due to rupture of the spleen. Cardiovascular lesions. apoplexy. embolism. ruptured aneurysm accounted for 25; pleurisy. without or with adhesions perhaps tuberculous caused 22 (there is a special belief in France that pleuritic adhesions explain sudden death though Dr Cristau does not hold it): no cases are attributed directly to renal disease. but 7 to pulmonary œdema secondary to heart or kidney lesions; 5 are ascribed to alcohol. which brought vomited matter into the larynx. Five are attributed to primary inhibition of the heart. Dr Cristau who complains of the human tendency to give a definite diagnosis without absolute certainty, quotes the only case that he thinks must have been due to cardiac inhibition: it happened to a man who had never complained of illness just as he had fired his rifle on the range. A very thorough post-mortem gave no other definite suggestion; all the organs were slightly enlarged but with no definite change. only the heart was empty and dilated. In some cases it is difficult to state the cause of death exactly because there seem to be possibly two or more—e.g. pulmonary infarction with endocarditis; in others not even one probable cause can be found. A prisoner had complained vaguely of constipation and died at the latrine; except for a large sarcoma at the bifurcation of the abdominal aorta no lesion was found. nor was there any hæmorrhage. Of what, then did this man die? That these cases of unexpected death may be the fewer the author advises the careful examination of all persons who complain of even seemingly trivial illnesses. As we read his cases. it is clear that several would not have been seen in a voluntary army. for many men must be taken for service in a conscript army who would not be accepted as volunteers. It should also be noted that of 22 sudden deaths reported in detail eight were from native troops.

THE RETICULATED RED BLOOD CELL.

THAT certain of the red cells in human blood show peculiar filamentous structures when coloured in the fresh state by methylene-blue or any of the so-called vital stains has been recognised since the application of these staining methods to the blood by Ehrlich at the end of last century. It became apparent from the observations of various authors that the relative proportion of the reticulated to ordinary red cells varied according to the activity of the blood-forming organs. In the normal human subject reticulated cells constitute about 1 per cent. of the whole number but in such conditions as blood regeneration after hæmorrhage this proportion may be greatly increased. In fact the reticulated red cell count probably offers the surest indication of the state of activity of the hæmatopoietic system at any given time. This being the case it is somewhat surprising that the procedure does not at the present time occupy a more prominent place in the armamentarium of the clinical pathologist. Dr. Dameshek's recent publication[1] of routine reticulated red cell counts undertaken in the Boston City Hospital, reveals their value as an index to the activity of the bone-marrow. In pernicious anæmia the reticulated cells usually form about 5 per cent of the whole—a fact which accords with the generally accepted view that pernicious anæmia is essentially a regenerative anæmia. A rise in the percentage of reticulated cells was found to be inseparably associated with the approach of a remission while the persistence of low percentage was of bad prognosis. In aplastic as opposed to pernicious anæmia. reticulated cells are almost absent. their proportion falling far below the normal of 1 per cent. Dr Dameshek makes some observations upon the relationship of reticulated cells to platelets. He found that increase of platelets in the circulating blood is usually accompanied by an increased percentage of reticulated cells. In conditions such as the thrombopenias associated with splenomegaly. the principal clinical feature of which is purpura. he found that so long as the thrombopenia persisted the reticulated count was low. With remission of the thrombopenia. however. whether occurring in course of nature or after removal of the spleen the reticulated count at once rose above normal. One result of his investigations was to bring to light a point in the differential diagnosis between Banti's disease and hereditary hæmolytic anæmia. In the former the reticulated count is either normal or not greatly increased: in the latter the public health organisations A health centre was established in a specially erected wooden pavilion, a public health nursing service was organised, and a number of clinics were opened The National Child Welfare Organisation started a clinic for expectant mothers, and another for children between 3 and 6, in addition to the babies' clinic and the school medical service which already existed. The National Anti-tuberculosis, Antivenereal and Mental Hygiene Leagues also lent their support and organised local clinics A dental hygiene service was opened. The local Red Cross undertook the propaganda, organised a local Junior Red Cross Section in the schools, and obtained the support of teachers, clergy, employers, workers, mutual benefit societies, and the press The staff of the demonstration consists of eight doctors in practice, three dentists, one head nurse, five visiting nurses, one nurse doing clerical work, and one social worker The report states that out of the 14 medical practitioners at Jumet, eight have given their services daily to the demonstration, and the remainder have always been ready to lend their aid when the occasion arose One of the most striking points of the demonstration is the institution of preventive medical examinations In spite of the fact that this is an innovation not easy to popularise, at Jumet 1476 persons, or 5 per cent of the population, voluntarily submitted to medical examination in 1925, although the examination was not free Another interesting feature is the participation in the demonstration of the workers and employers through their unions The glass-workers' union bought 700 health pamphlets for distribution among its members. The annual budget of the demonstration amounts to about £600, which works out at about 5d per head of population The report considers that the three main accomplishments of the demonstration so far are (1) the establishment of cooperation between the various institutions and organisations which had been working along the same lines but without any unified plan ; (2) the whole-hearted way in which the medical committee has entered into the demonstration, and the undertaking by doctors of preventive as well as curative work, (3) the awakening of a health conscience among the entire population, witness the fact that during 1925 40 per cent of the inhabitants of Jumet sought the preventive services established for their use

[1] The Reticulated Red Cells. Their Clinical Significance Boston Medical and Surgical Journal, 1926, cxciv., p 759

THE VOLUNTARY HOSPITALS IN 1926

Many of the voluntary hospitals are now holding their annual meetings, and although their printed reports are in most cases not yet available, it is possible to form a fairly trustworthy impression of their general situation at the end of 1926 Broadly speaking, they had a better year than might have been expected in view of the long period of industrial unrest caused by the mining dispute The General Strike, during the short period for which it lasted, caused them serious inconvenience and sometimes sharp discomfort and, especially in the great towns of the Midlands and the North, the vast mass of unemployment produced by the closing of the collieries heavily reduced the receipts from those contributory funds upon which they are every year more closely dependent Yet it would not be surprising to find, when the detailed figures of the year are published, that they increased their aggregate income and that a larger number are able to present a clean balance-sheet as regards the cost of maintenance Were it not so the outlook for the voluntary system would be black indeed, since expenditure must necessarily grow It is not merely that everything costs more, but that no hospital is able to stand still. More patients and more clinical facilities react upon each other, the more hospitals can do for patients, the greater the number and the eagerness of patients It is difficult for hospitals to economise in any direction, and in many directions it is undesirable that they should. Businesslike management is rapidly becoming one of the hospital fine arts, and it may be taken for granted that, broadly speaking, there is no waste of money in any direction The hospitals must therefore look for increased resources As regards current expenditure many of them are finding salvation in the establishment and enlargement of contributory schemes which possess the cardinal advantage of almost infinite elasticity Soon they are likely to be universal

The paying patient is beginning to acquire importance as a producer of income, and schemes of extension now very commonly include provision for him This matter of enlargements raises very serious questions Surplus income, when there is any, is usually not available for building new wards which, by reason of the growing costliness of their equipment, swallow enormous sums, and so far no substitute has been found for those "special appeals" which confront us daily The contributory scheme and the paying patient are already with us, and both are growing in importance But what of the patients who ought to be paid for but are not? They are pitchforked into the hospitals in more and more thousands every year as the result of speed-madness They demand urgent attention, they cost much money, and lengthen those waiting lists which, when all reserves have been made, remain a sad reality It has become urgently necessary to devise means for bringing a large proportion of accident patients into contribution, either directly or through the organisations in which they are insured Meanwhile there is abundant room, not merely for congratulation, but for faith and hope The voluntary hospitals, taken all round, have done unexpectedly well in a difficult year, on every hand plans for enlargement of buildings and improvement of equipment are being perfected The resilience of the voluntary system is the most conclusive proof of its inherent value So thoroughly, indeed, has that value been demonstrated that talk about the nationalisation or municipalisation of the hospitals has grown so faint as to be almost inaudible.

THE TREATMENT OF MENTAL DEFECTIVES

The Mental Deficiency Act of 1913 had good intentions Conceived as a means of satisfying the two outstanding needs of the years preceding its contrivance it was hoped, first, to afford facilities for the better care and treatment of the feebleminded, and, secondly, to effect such arrangements as would ensure the transfer of their supervision and control from the legal to the medical authority Unfortunately, this "charter of the feebleminded" had that within its constitution that was doomed to bring it failure Time has shown that obvious idiots and imbeciles could not be dealt with in accordance with its requirements, and in their reports the Prison Commissioners often have recorded their inability to afford their defective criminals its benefits By defining the degrees of mental defect as definite legal entities, by effecting thus an arbitrary classification of clinical conditions not always easy to realise in actual practice, by insisting that only such aments as appeared to be members of these statutory classes should be dealt with, and by requiring, in every instance, that certification shall precede treatment, this important measure unduly restricted the range of its usefulness and successfully frustrated the primary purpose of its initiation

There was a hope that an amending Bill, valuing its opportunity, would endeavour to remedy these defects That hope has not been fulfilled Neither in the Bill of 1926, nor in Mr Crompton Wood's measure, whose second reading is to be heard in the House of Commons on March 18th, is there any indication of even a recognition of the fundamental flaws of the principal Act As these measures are the first to deal with mental conditions since the rising of the recent Royal Commission on Lunacy and Mental Disorder, it is to be regretted that as far as these two Bills are concerned it would seem have had an attack of typhoid fever in his youth This retrospective diagnosis which recalls the methods of Sir Conan Doyle's hero turned out to be correct having been suggested by the pale transverse striæ above the patellæ Striæ patellares are probably of mechanical origin The splitting or cleavage in the deeper layers of the cutis which gives rise to the phenomenon is due partly to rapid growth which is likely to occur after acute infectious diseases, and partly to the flexed attitude assumed by the patient lying in bed Dr. Parkes Weber however, in his discussion on Dr Rolleston's patient, suggested as a further factor in many of these cases an abnormal trophic condition of the cutis which diminished its normal elastic distensibility and even increased the tension present in the skin of all normal young persons

POST-VACCINAL ENCEPHALITIS

NOT only a prophet but the outcome of the investigations of a government committee may be famed abroad while unknown in the country of its origin A correspondent gives on p 619 an interesting survey of the world-literature of post-vaccinal encephalitis Among the communications to which he draws attention is one made by Prof Ricardo Jorge, director-general of Public Health in Portugal to an international conference held in May and June 1926 [1] Dr Jorge refers in the course of an exhaustive discussion of the available evidence to the report placed before the Comite de l Office International d Hygiene Publique at a previous meeting held at The Hague in May, 1925 This report apparently embodied the findings of a committee appointed *ad hoc* by the Ministry of Health of Great Britain under the chairmanship of Sir Frederick Andrewes Dr. Jorge praises the report as an extremely abundant source of information comprising systematic inquiries about cases statistical analyses topographical and chronological research into ætiological and epidemiological relations, and finally a complete discussion of all imaginable hypotheses as to the nature of this encephalitis From the data supplied he has compiled the following table:—

	No of cases	Years
England	62	1922–24
Holland	36	1924–25
Switzerland	2	1924
Czecho-Slovakia	7	1923
Austria	18	1924–25

Dr Jorge says that "la commission Andrewes" considered, in turn three questions: (1) whether the encephalitis is connected with the inoculation of vaccine in the direct relation of cause and effect, (2) whether on the contrary, another known virus such as that of poliomyelitis or encephalitis lethargica, has intervened having found a portal of entry in the vaccination lesion, (3) whether some still unknown virus is the cause of the condition According to him each of these theories in turn was formally rejected by the commission though it is difficult to see how they could all be wrong He quotes with approval the following words of Prof J McIntosh but gives no indication of their context: 'I am strongly of the opinion that we have had to deal with a hitherto undescribed lesion of the central nervous system' In this connexion we may recall that in a paper published last August, Prof H M. Turnbull and Prof McIntosh [2] published records of seven cases in which, they assert there can be no doubt that vaccination was a definite causal factor They describe the typical histological appearances of the lesions found the most important characteristics being the number and size of zones of extra adventitial perivascular infiltration in comparison to the development and size of adventitial vascular sleeves: and the extensive distribution of the lesions. This elaborate study was published only after the report of "la commission Andrewes" had been handed to the International Conference at The Hague but since Turnbull and McIntosh sent reports on the histological and experimental investigations described therein to the Ministry of Health in 1924, doubtless their findings received consideration. Meanwhile, in April 1926 we were asked to give publicity to the formation of another committee, under the auspices of the Ministry of Health to investigate cases of encephalitis directly following vaccination, and practitioners were requested to inform its secretary, Dr. J. R. Hutchinson of any cases which came under their observation In view of the international importance of clearing up the ætiology of this form of encephalitis, it may be hoped that the report of this committee will not be long delayed.

The Services.

ROYAL ARMY MEDICAL CORPS

Maj B Biggar is restored to the estabt.

Temp Capt. M Ferguson relinquishes his commn., and is granted the rank of Capt.

SUPPLEMENTARY RESERVE OF OFFICERS

Lt. A G Henderson to be Capt.

TERRITORIAL ARMY.

Lt.-Col. (Bt Col) G L. Thornton, from R.A.M.C, to be Col. and to be A.D M.S 43rd (Wessex) Div T.A., vice Col A. B. Soltau K.H.P, who vacates that appointment.

Capt. H C C Hackney to be Maj

Supernumerary for Service with the O T C—Maj W J. A. Laird, Res. of Off., resigns his commn. in the T.A.

INDIAN MEDICAL SERVICE

Lt.-Col. W. O'S Murphy to be Col.

Capts. H Aung Khin and Malik Anup Singh to be Majs.

Capt. M F D Graham resigns his commn

ROYAL MEDICAL BENEVOLENT FUND.

AT the last meeting of the Committee 38 cases were considered and £746 10s voted to 36 applicants. The following is a summary of some of the cases relieved:—

L.R C P & S, aged 63 who through illness has been unable to take up his locum work and is now in hospital. To meet his expenses an emergency grant of £5 was sent and a further sum of £40 voted

M R C S Eng aged 57, held an assistantship until taken ill in December last, and is now in a nursing home. Only assets £120 capital and about £50 worth of furniture. Fund sent 10 guineas and voted a further £40 payable in six instalments

Widow, aged 67, of M.R.C S. Eng. who died in 1914 Through failure of investments and the loss of a son who contributed to her support, has had to take a post as housekeeper. During the last two years has broken her arm and twice broken her ankle Has £62 from two pensions and £60 as housekeeper. Debts £20 Voted £10

Daughter aged 40 of M.B Aberd. who died in 1906 Supported herself as a clerk until 1925 when she had a serious breakdown. Now entirely dependent on her sister, who is a bank clerk. Mother who died in 1923 was a grantee of the Fund. Applicant asks for a temporary grant. £10 voted.

M.R.C S Eng aged 66 married. Sons killed in the late war Has suffered from ill-health for the past 15 years Has an allowance of £120 from a sister and £27 from the Ministry of Pensions House belongs to wife and the rates amount to £13 per annum. Debts £55 Voted £30

Widow, aged 60, of M.R.C S Eng. who died in 1924. She is a trained nurse but delicate Applicant let her house furnished but has had no rent for three months and has taken an action against the tenant for recovery Has a pension of £50 a year and £8 10s from children who are both married. Voted £26 in monthly instalments

Daughter aged 60, of M.R.C.S Eng who died in 1913 On account of age has had great difficulty in finding employment as a dispenser and last year only made £82 From investments received £24 Board and lodging £90 Voted £12 in 12 instalments.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters Symonds, at 11, Chandos-street, Cavendish-square, London, W. 1.

[1] Office International d Hygiène Publique Bulletin Mensuel, tome xix, No 1 January 1927

[2] See THE LANCET, 1926 ii., 504

percentage of reticulated cells seldom falls below 15 and is frequently in the neighbourhood of 50 In the words of the author, "a palpable spleen with a high (reticulated red cell) count equals either hæmolytic or pernicious anæmia, whereas a spleen with a normal or slightly raised count belongs to the Banti or cirrhosis group." The author's technique for the performance of the reticulated red cell count is simple Brilliant cresyl blue, 0 3 per cent. in alcoholic solution, is used Slides are kept on hand, having at one end a dried drop of dye A drop of blood is placed on a cover-slip which is inverted on the dye, and the two are allowed to mix for from three to four minutes The count is made with a high dry or oil immersion objective and with an eyepiece furnished with a square diaphragm One thousand red cells are counted and the proportion of reticulated cells noted

ISAAC NEWTON.

IT will be 200 years to morrow (Sunday) since the death of Isaac Newton, which occurred on March 20th, 1727. In a sense Newton's fundamental discoveries along the whole range of mathematics and the related physics had no immediate bearing upon medicine save in the realm of optics, nor, as we know from his life, had the phenomena of disease any attraction for him But such profound revolutions of thought as were brought about by the publication of the "Principia" were bound to have an immediate and enlightening effect upon all medical and biological work. The machinery for research became facilitated, and, above all, the attitude in which discovery should be pursued became evident, with the result throughout Europe that pathology assumed a scientific status which it had never before attained, as the leaders of thought appreciated the significance of the new knowledge The influence of Newton upon medicine was undoubtedly indirect, but medicine shared with all science the benefits derived from the grand enlightenment.

THE NATIONAL UNION OF SCIENTIFIC WORKERS.

THE National Union of Scientific Workers was founded in 1918 with the objects of promoting the cause of natural science in our national life and of improving the status of the scientific worker It is entirely non-political and has definite economic and cultural aims. It has already been successful in securing improvements in the conditions of service of scientific workers in Government and private employ, and has intervened in a variety of matters in which the importance of scientific research has needed emphasis. The Union has, however, failed to incorporate more than a proportion of these who are qualified for admission, the membership is still less than a thousand, and in an attempt to extend its activities it has lately issued a general statement of its aims along with an invitation to workers to express their opinions on the question as to how the Union may best achieve its objects The appeal is supported by a very weighty list of names distinguished in science and in public life. We do not doubt that such an organisation may be effective and sometimes useful, but we question whether those who are promoting it have sufficiently considered the psychology of the group mind, and have found a common ideal which will unite all the members they desire to attract into a corporate whole "Scientific workers" have a common technique in so far as they proceed by experiment and mathematics But their aims are by no means so similar, and it is at least doubtful whether their ideals are sufficiently homogeneous to form a bond of union between them which will stand more than the slightest strain. The British Medical Association promotes cultural and economic aims in the same way, and is successful because the members are all united by a real community of training and practice We can imagine that many members of the National Union of Scientific Workers might band themselves together as university teachers But it seems unlikely that they will easily and harmoniously run in double harness with those whose object in life is (or from their occupation ought to be) to earn dividends for shareholders in competitive chemical manufacture. Recent events to which THE LANCET has drawn attention bring out plainly the point over which disruption seems certain to come sooner or later, the Union is attempting to unite persons with ideals as different from each other as the ideals of those who would exploit medical discoveries for private gain are from those of the rest of the medical profession. One scientific worker has no necessary kinship with another scientific worker; it all depends on what ideal he is serving with the technique of scientific work

AN INTERESTING COMMEMORATION.

A GATE in commemoration of the work of Sir Ronald Ross, erected near the north entry to the Presidency General Hospital, Calcutta, was opened on Jan 7th by Lord Lytton, the Governor of Bengal The memorial, which bears a medallion portrait of Sir Ronald Ross and an apposite inscription, faces one of the principal traffic routes of the city and will be passed by thousands of persons daily, who will thus be reminded that in a small laboratory a few yards from its site Ross's great discovery was made. Lord Lytton in an eloquent speech pointed out that Calcutta, although the birthplace of the knowledge had as yet derived less benefit from antimalarial work than other parts of the world, and instanced Panama, Ismailia, West Africa, and the Malay Peninsula as all owing freedom from malaria to the work they were assembled to commemorate He welcomed Sir Ronald Ross on his visit to Calcutta with pride, and suggested that belated gratitude to him should take the form of an intensive campaign against malaria in Bengal Sir Ronald Ross, in reply, associated himself with the labours of those who had preceded him in working out the problems, and described himself as living the proudest moment of his life The commemoration ceremonies were organised by Colonel Megaw, head of the School of Tropical Medicine in Calcutta, who in an introductory speech spoke forcibly of the chilling atmosphere in which Ross's work had been done, of his dogged perseverance, and of the need of a tangible memorial seeing how general the ignorance was of what had been done.

STRIÆ PATELLARES.

THE condition of striæ patellares, of which Dr J D. Rolleston[1] recently showed an example at the section for the Study of Diseases in Children of the Royal Society of Medicine, is a localised form of that phenomenon which has received various names, such as striæ atrophicæ, striæ cutis distensæ, or striæ albicantes, and is called *vergetures* by the French and *falsche Narben* by the Germans It is manifested by the appearance above the upper border of the patellæ of symmetrical transverse striæ, which at first are red or purplish in colour, and then gradually become pale, like the more familiar striæ atrophicæ associated with pregnancy Though the condition has received considerable attention in France where it was first described by Regnier in his Paris thesis in 1860, as well as in Germany, not much has been written on the subject in this country, apart from articles by Dr J Bunch and Dr. F Parkes Weber It is met with after many infectious diseases, but is commonest after typhoid fever, as was exemplified in the patient, a girl aged 14, shown by Dr Rolleston, who stated that he had seen another case following paratyphoid B Bleibtreu in an article published in 1905, when typhoid fever was commoner than at present, relates how his chief, Prof Leichtenstern, surprised his audience and the patient whose knee-jerks he was examining by saying that the man must column of food falls below 8 in. (Fig. 3). Consequently the patient is able to obtain just sufficient nourishment to maintain a low level of nutrition, but the œsophagus is constantly full: food does not regurgitate from it even on lying down as the upper sphincter is closed, except during deglutition, though by a voluntary effort the œsophagus can generally be emptied. The obstruction offered by the cardiac sphincter results in over-action of the œsophageal muscle, which becomes greatly hypertrophied, and the accumulation of food leads to enormous dilatation. The sphincter, however, remains unchanged, the hypertrophy, which would be present were there an element of spasm, being never observed.

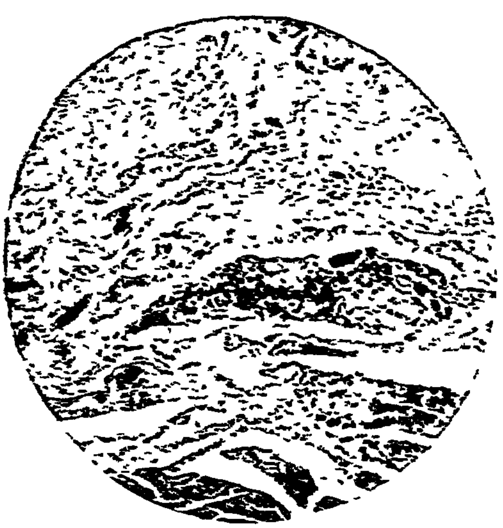
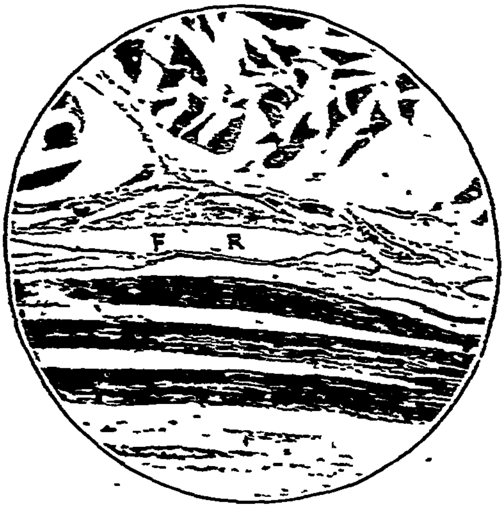
FIG. 5.



Microphotograph of ganglion showing cell infiltration and degeneration of ganglion cells in achalasia of the cardia. (G. W. Rake, Guy's Hospital Reports, vol. lxxv., No. 2, 1925.)

FIG. 6.



Section through cardiac end of œsophagus in Mr. Grey Turner's case of achalasia to show cell infiltration (R) and fibrosis (F) of Auerbach's plexus, and complete disappearance of ganglion cells, none being seen in any of 50 serial sections. × 50 (Prof. Adrian Stokes.)

Achalasia of the cardia must be due to interference with the normal neuromuscular mechanism which leads to the relaxation of the cardiac sphincter on the arrival of each peristaltic wave. Occasionally this is the result of some organic disease involving the vagus such as tabes or peripheral neuritis: occasionally it is reflex and secondary to irritation of the œsophagus by adhesions to a tuberculous gland, or to an ulcer or growth of the stomach. In the large majority of cases no obvious cause is found: the condition is then probably due to inflammation, degeneration, or syphilis involving the nerve-plexus of the sphincter, strictly analogous with the local diseases which give rise to heart-block. Since I suggested this possibility[2] three cases have been investigated pathologically at Guy's Hospital: in the first, Rake[3] demonstrated well-marked inflammatory and degenerative changes in the lower end of the œsophagus, particularly involving Auerbach's plexus (Figs. 4 and 5): in the second and third specimens, sent respectively by Mr. Grey Turner, of Newcastle-on-Tyne, and Mr. J. Morley, of Manchester, Prof. Adrian Stokes found that the whole of the nerve-plexus in the neighbourhood of the cardiac sphincter had been destroyed and was replaced by fibrous tissue (Fig. 6).

Physician to Guy's Hospital.

(*To be concluded.*)

Special Articles.

ACUTE DISEASE OF THE CENTRAL NERVOUS SYSTEM ASSOCIATED WITH VACCINATION.

CASES of encephalitis following or occurring in the course of acute infectious diseases have been reported in the medical journals from time to time during the last few years. No doubt the severe epidemics of diseases of the central nervous system which have occurred in the last 20 years have made medical practitioners more alert in diagnosing and more exact in describing cases of meningitis, poliomyelitis, and encephalitis lethargica which formerly were regarded as rare or even unprecedented, except by the specialist in nervous diseases, and passed unexplained. Knowledge of these diseases and their differential diagnosis has been greatly improved by additions to clinical methods such as lumbar puncture and chemical, microscopic, and cultural examination of the cerebrospinal fluid.

Cases of encephalitis or *meningitis serosa* in the course of measles and varicella have probably actually occurred more frequently and have certainly been more often recorded during the last five or six years. Winnicott and Gibbs[4] collected 12 cases of varicellar encephalitis. A recent review by E. Glanzmann[5] of the nervous complications of varicella, variola, and vaccinia, mentions five cases of encephalitis after chicken-pox. He also mentions 13 recorded cases of small-pox in which nervous complications, especially aphasia, appeared on dates fairly evenly distributed between the second and twenty-eighth day of the original disease. F. Lust (1926) recorded four cases following measles and mentioned nine recorded by others.

Encephalitis following Antivariolous Vaccination.

The subject has acquired additional interest and importance from the occurrence of a number of cases of encephalitis following antivariolous vaccination. General attention was first drawn to the subject in the medical press by F. Lucksch[6] in 1924. He described three fatal cases which he had observed in Bohemia in 1923, all of which were taken ill exactly ten days after vaccination. The vaccination itself had run a normal course without apparent excessive reaction.

CCXV.

TREATMENT OF ACHALASIA OF THE CARDIA
(SO-CALLED "CARDIOSPASM")

I *—GENERAL CONSIDERATIONS

THE mouth of the œsophagus is closed during rest by the tonic contraction of the inferior constrictor of the pharynx The lower end is closed by the cardiac sphincter This is a definite structure from 1 to 1¼ in in length (Fig 1), it constitutes the intra-abdominal portion of the œsophagus and may extend a short way above the diaphragm Its muscular coat is very slightly thicker than that of the rest of the œsophagus, and its mucous membrane is thrown into longitudinal instead of transverse folds The nerve-plexus of Auerbach between its muscular coats is well developed, forming a special "nodal tissue," similar in structure to the neuromuscular nodes of the heart

FIG 1.

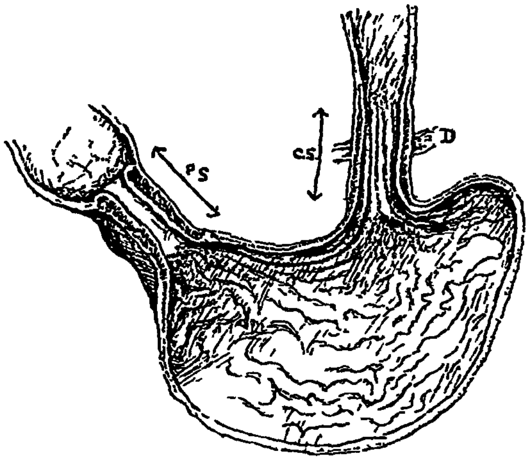

Diagram showing the stomach of a full-time fœtus CS, cardiac sphincter, with deep, pale, longitudinal rugæ and thickened circular muscle D, diaphragm attached to centre of sphincter PS, pyloric sphincter

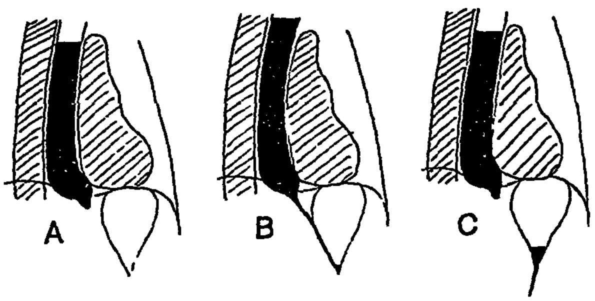
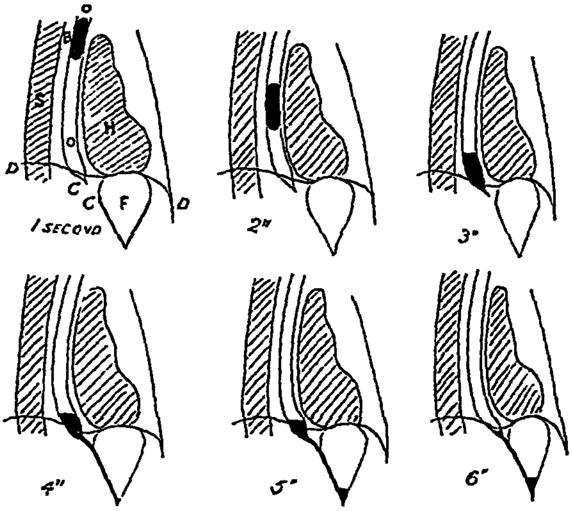
FIG 3



Diagrammatic drawings of œsophagus in achalasia of the cardia A, shows column of barium-containing food, 8 in high, above closed cardia B, after additional quantity of food swallowed, so that the taller column, being heavier, opens cardia and allows surplus to enter stomach C, Return to condition of (A) after surplus food over the 8 in column has entered stomach

Physiology —In the process of swallowing food is thrust through the pharynx by the action of the tongue, the upper sphincter relaxes and permits it to enter the œsophagus, down which it is propelled by peristalsis When a peristaltic wave passes down a muscular tube, the wave of contraction is preceded by a wave of relaxation, consequently when the diaphragm is reached the cardiac sphincter relaxes, and the food passes through it into the stomach, after which the sphincter once more closes in order to prevent regurgitation into the mouth (Fig. 2)

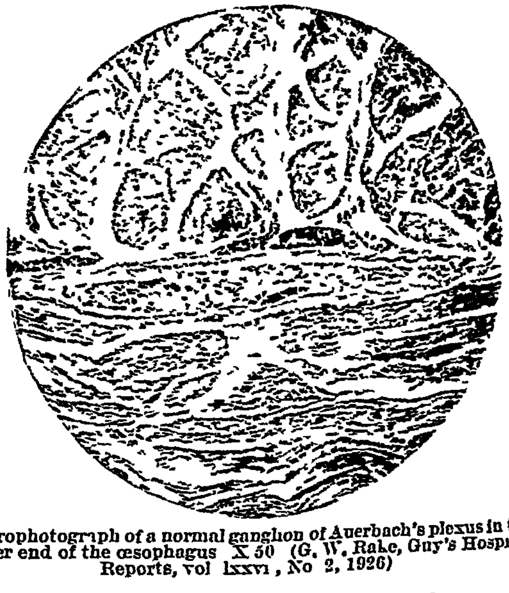
FIG 2



Diagrams of the passage of a bolus of barium containing food (B) through the œsophagus (O O), as seen with the X rays in successive seconds after swallowing S, spine, H, heart, D D, diaphragm, C C, cardiac sphincter, F, fundus of stomach

Pathology —Achalasia of the cardia is a condition in which the cardiac sphincter does not relax (α, not, χαλαω, relax) in the act of deglutition [1, 2], the food is retained in the lower end of the œsophagus, the peristalsis of which is not sufficiently strong to overcome the resistance offered by the closed sphincter More and more food accumulates until a column 8 in high is formed, the pressure exerted by this is just sufficient to overcome the resistance of the cardiac sphincter, so that any additional food now taken forces that in the lower end of the œsophagus through the sphincter, which closes again directly the height of the

FIG 4.



Microphotograph of a normal ganglion of Auerbach's plexus in the lower end of the œsophagus × 50 (G. W. Rake, Guy's Hospital Reports, vol lxxvi, No 2, 1926) thousands of children have been vaccinated without bad results with Levaditi's "neurovaccine" which had been repeatedly passaged through the brain of rabbits

[2] A. F Hurst Quart Jour Med, 1914, viii, 300, and Medical Essays and Addresses, p 110, London, 1924

4 The suggestion that on the average about 1 in 10,000 of all vaccinations is followed by encephalitis is scarcely compatible with the special incidence in certain countries and parts of a country. Bastianse found strong evidence of factors connected with time and place which determined the incidence of cases In two large towns of over 100.000 inhabitants each there was one case in 30 000 of the population and 1 in 9000 of vaccinations In towns of under 5000 inhabitants there was 1 in 2000 of the population and 1 in every 63 vaccinated

5 The special histological peculiarities of the post-vaccination encephalitis described by Turnbull and McIntosh are not universally accepted and the great variability of the pathological anatomy and histology in encephalitis lethargica make exclusion of this disease difficult on these grounds

6 The clinical features in some cases strongly suggest encephalitis lethargica and, in any case. are not sufficiently uniform to constitute the definite syndrome of a new and distinct disease

In favour of the view of Bastianse, Levaditi, Kraus, Zurukzoglu, and others that the post-vaccination encephalitis is Economo's disease with vaccination acting as an exciting and modifying cause in persons incubating or carrying the virus of the former. are: (1) The general morbid anatomy and clinical history (2) The great prevalence of the disease during the last few years. which in some instances has been especially accentuated in the time and in the country where the cases of post-vaccination encephalitis have occurred (3) Kraus and Takaki. by a special technique which had been worked out with herpes virus and serum from lethargica patients obtained fixation of complement with the central nervous system of fatal cases as "antigen" and serum from cases of encephalitis lethargica but not with serum immune to vaccinia. (4) Experiments in which herpes virus inoculated subcutaneously in rabbits has caused encephalitis when vaccinia has also been injected intravenously at the same time have been brought forward by Zurukzoglu as evidence that vaccinia produces a susceptibility of the brain to herpes or other encephalitic virus

The experimental evidence brought forward in support of these views by Kraus and Takaki and by Zurukzoglu involves the acceptance of the identity of the virus of herpes encephalitis and that of encephalitis lethargica This identity is not generally accepted, though supported by Levaditi and Perdrau. Most experimenters have completely failed to infect animals with lethargic virus, and such successes as have occurred are widely held to be due to concomitant infection of the patient or the rabbit with herpes virus

Conclusion.

Between the views which attribute the actual encephalitis to vaccinia and to encephalitis lethargica or herpes virus respectively are a number of grades of opinion according to which endemics and epidemics of such diseases as Economo's encephalitis poliomyelitis and even cerebro-spinal meningitis are taken as evidence of a general predisposition to disease of the central nervous system and vaccination as an exciting, predisposing or merely additional factor. These views and their possible modifications have been ably discussed by Sobernheim.

The only possible conclusions to be drawn with certainty are that the cases of post-vaccinal encephalitis do result from vaccination at least as a contributory cause but that the immediate cause of the encephalitis is probably not an ordinary bacterial infection but some living ultravisible virus. To the question what is the exact nature of this virus the answer is less sure but the evidence points decidedly against the vaccinia virus acting alone. and there is a further probability that virus of encephalitis or possibly that of poliomyelitis has an important share in the production of the cases of disease Which of these viruses is active in a given case may depend on the prevailing epidemic or season. In either case the course of the disease and character of the symptoms may not improbably be modified by the vaccinal infection Since encephalitis lethargica has not so far been certainly communicated to animals, unless the virus of herpes is eventually shown to be a form of the same infective agent. experimental failure to infect rabbits or monkeys from post-vaccination cases of encephalitis does not help to decide whether that virus is playing an active part

---

MEDICINE AND THE LAW.

The Position of the Medical Witness.

A CASE of some interest came lately before the Banbury County Court Dr Alan Forty. of Shenington. made a claim for 10*s* 6*d*. because of the principle involved namely. the right of the medical man to be paid for a medical report affording help in the course of legal procedure which could not be classed as the ordinary help which a member of the public would be able to give at the request of the police. The facts are these Dr. Forty received a message that two men had been injured in the overturning of a motor car. He found a constable in charge. examined the driver of the car and formed the opinion that he was not under the influence of drink The following day the constable asked him to make a report with reference to the condition of the driver. which was done. the report in writing being accompanied by an account for 10*s* 6*d* In reply Dr Forty received an intimation that his claim was not understood, inasmuch as he had supplied only the help which it would have been the duty of any other person to render to the police A claim was then brought by the London and Counties Medical Protection Society for Dr Forty against the Chief Constable of the County. who said in court that payment was opposed as being a matter of concern to the ratepayers Judge Staveley Hill said that the case was interesting, though the amount involved was small. He held that the plaintiff had not substantiated his claim. as he was not called in by the police. He did not consider that the writing of a report later made the assistance which Dr. Forty had rendered to the police any different from that which might have been given by an ordinary witness. He gave judgment for the defendant, but without costs It is clear that His Honour recognised that Dr. Forty's claim was made on principle. and that the Chief Constable of the County had opposed payment for the same reason. The matter cannot apparently be carried further as an appeal would probably not be allowed. because it would be founded on a question of fact, and not on a point of law. but to medical men the decision of Judge Staveley Hill will not appear satisfactory. The assistance that was given by Dr Forty to the constable in charge of the case was distinctly of medical or expert nature. An investigation of the condition of the driver might have had considerable bearing on the sequel. when the medical qualifications of a witness would have been all important. No layman who happened to be on the scene of the accident would have been able to give the authoritative assistance that could be rendered by a doctor.

ST. LUKE'S HOSPITAL.—The Governors of St Luke's Hospital have acquired three houses. standing together in eight acres in Woodside Avenue. Muswell Hill Further buildings are to be erected and it is intended to use the whole establishment as a nursing home for nervous cases and for clinical purposes.

A HOSPITAL AMALGAMATION.—It has been decided to amalgamate the Plymouth Ear and Throat Hospital with the South Devon and East Cornwall Hospital On the other hand, the Governors of the Bristol Royal Hospital for Sick Children have rejected a proposal to work in conjunction with the Royal Infirmary

Lucksch at first regarded these cases as typical cases of encephalitis lethargica on the grounds of clinical symptoms and of pathological anatomy and histology Later, however, he was led to blame the vaccinia virus for the changes in the brain Cases with similar symptoms and all suggesting acute intracranial inflammation have now been described from Holland, Austria, Switzerland, France, England, Greece, and Czecho-Slovakia The earliest recorded case appears to have come under the observation of Comby in 1905 and to have been recorded with two others in 1907. Comby refers to these and narrates an additional and recent fatal case [7] Prof R Jorge [8] recently reviewed all the evidence concerning post-vaccination encephalitis, and gave the numbers recorded in different countries England, 62, Holland, 36; Switzerland, 2, Czecho-Slovakia, 7, and Austria, 1. He also discusses the report of the committee appointed by the Ministry of Health to investigate the subject, which has not yet been published in this country Five fatal cases of post-vaccinal encephalitis occurring in this country which closely resembled those reported from the continent were recorded by Turnbull and McIntosh,[9] and G van Rijnberk [10] states that 62 such cases with a 56 per cent mortality have occurred in England A Departmental Committee on Vaccination has been appointed by the Ministry of Health, and on April 24th, 1926, an invitation to the medical profession was published in THE LANCET and *British Medical Journal* to send information to this committee of any cases of disease of the central nervous system arising within four weeks of vaccination No doubt the committee will report in due course, but so far no information on the subject has been published

Though not all have had quite the same history and symptoms the majority have been alike in certain particulars and especially in the time of onset of the acute cerebral condition which has been in most cases 8 to 12 days after vaccination The symptoms have indicated acute encephalitis, but without, as a rule, evidence of meningitis Permanent local paralysis, which is so characteristic of acute poliomyelitis and other lasting sequelæ common after encephalitis lethargica, are almost absent from the records

The largest series of cases reported from any one country was observed in Holland This has been fully discussed by F. S B v. Bastiaanse, P Bijl, and J. Th Terburgh.[11] These writers state that 35 cases occurred between Jan 1st, 1924, and the end of June, 1925, whilst about 250,000 children were vaccinated in the same period Thirty-three of the cases were in children of 3 to 6 years, and at these ages 79,936 children were vaccinated during 1924 alone, out of a total of 161,145 vaccinations under 13 years of age The proportion of vaccinated children attacked was therefore very small and selection of a special age by the disease very definite

The period which elapsed between vaccination and the acute onset of encephalitis was 5 to 23 days Usually the first symptoms occurred on the tenth to the twelfth day (24 cases) Vomiting, headache, and high fever followed by drowsiness and convulsions were the chief symptoms The acute stage lasted 7 to 15 days and 15 of the children died (42 per cent) There was a notable absence of sequelæ in those that recovered During February, March, and April, 1925, about 122,000 persons were vaccinated and 24 cases of post-vaccinal encephalitis occurred—i e, 1 in 5000—but during the other nine months of that year with 151,000 vaccinations there were only 7 cases, or 1 in about 21,400 vaccinations The large area of Europe involved and the many different sources from which the vaccine implicated came negatived the idea that the disease could be due to contaminated vaccine, and the large number of children who were vaccinated with the same lymph and escaped complications pointed in the same direction The vaccine used in Holland came from 12 different calves which had been inoculated with five different strains of lymph, two from Holland, two German, and one from the East Indies Bastianse attributed his cases to infection with encephalitis lethargica which at that time was very prevalent The figures which he gives for the first months of 1925 strongly support this view.

In January there were 12 cases of encephalitis notified
In February 16 cases, of which 2 were post-vaccination cases
In March 51 „ „ 16 „ „
In April 27 „ „ 7 „ „
In May 10 „ „ 0 „ „

The increased number of vaccinations performed during the same period also suggested that the post-vaccination cases might be due to chance vaccination of children already infected with encephalitis lethargica

The Nature of the Disease

Bastianse recognised that the cases did not conform exactly to the usual type of encephalitis lethargica, since the onset was more sudden, the occurrence of paralyses very much rarer, and the mortality much higher, especially for children

The symptomatology of Economo's encephalitis is, however, notoriously varied, and there is also a tendency for the symptoms and the type of the disease to be slightly different in one country or in one group of cases to that occurring elsewhere. A similar variability is also found in the cases of post-vaccination encephalitis—e g, the trismus- and tetanus-like symptoms which occurred in Lucksch's cases Against the view that the essential cause of encephalitis is the vaccinia virus must be placed the almost invariable failure to detect this in the central nervous system of the children who have died and been examined post mortem The paper by Turnbull and McIntosh appears to contain the only published evidence of vaccinia virus being recovered from the brain or lumbar-puncture fluid of patients It is well known, however, that after the inoculation of rabbits with vaccinia on the skin the virus can be found in almost every organ, including the brain, for two or three weeks, if the search is thoroughly carried out, even though the lesions are confined to the skin

The question of the exact nature of these cases of post-vaccinal encephalitis occurring in so many countries and the share which vaccinia and other causes have in their production is not as yet determined Among all the writers who have reported cases or reviewed the subject there is general agreement that vaccination has some causal relationship to the cases, although they are relatively rare, about 1 to 1 4 in 10,000 vaccinations in Holland and Switzerland That the disease is simply vaccinal inflammation of the brain, as suggested by Turnbull and McIntosh, Lucksch, and others, and that it is perhaps due to an especially neurotropic strain of vaccinia appears to be negatived by the following considerations

1 Enormous numbers of children have been vaccinated in the past without cases of encephalitis resulting, at any rate, in numbers approximating to the present series, till quite recent years, and a large number of innocuous contemporary vaccinations are carried out

2 Except in one case there has been failure to detect any evidence of vaccinia virus in the brain of fatal cases, either experimentally by the inoculation of rabbits or serologically by the method of Kraus and Takaki Even if found its presence would not have the significance implied by Lucksch and Kraus, since its wide distribution in the body is believed to invariably follow vaccination

3 Large numbers of children have been vaccinated with the same strains of lymph which were used for those who subsequently became ill, and many

A PORTRAIT OF WILLIAM HARVEY

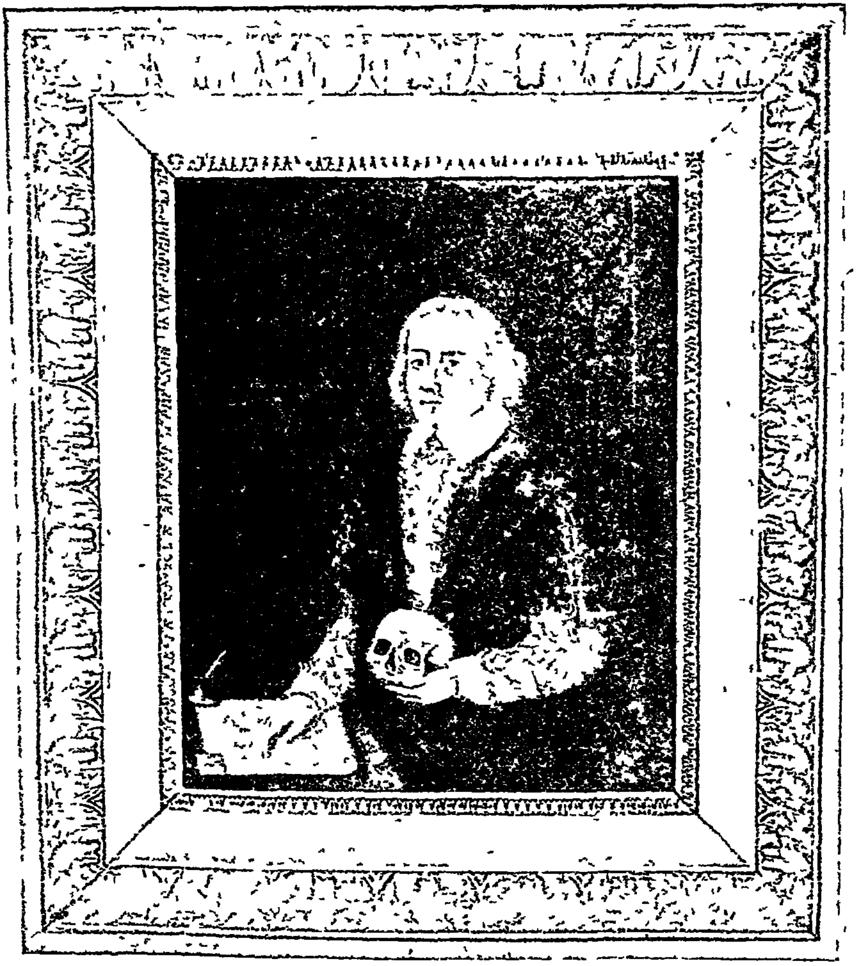
Observations and Notes by

Rickard W Lloyd, M R C S Eng , L R C P Edin

> " There thy Observing Eye first found the Art
> Of all the Wheels and Clock work of the Heart
> The mystic causes of its Dark Estate,
> What Pullies Close its Cells, and what Dilate
> What secret Engines tune the Pulse, whose din
> By Chimes without Strikes how things fare within "
> —M LL , M D [1]

This old picture bears as its title " Guilielmus Harveus, Anno Dom 1647 " the words are placed to the left of the face in the background, removing all doubt who is the subject of the portrait The question arises, was the picture painted by Lely? Among the *intrinsic* evidences in support of that are, in my opinion, the drawing, colour, and handling of the work, there is also the signature "P Lely" towards the right on the lower rim of the inkstand

Information upon the portrait and any *extrinsic* evidences of attribution would be very much appreciated by me The portrait is on an oak panel 12 inches by 10 inches There is a portrait of William Harvey by Cornelis Janssens in the Royal College of Physicians of London, where he was Professor of Anatomy and Chirurgery, and another from an unknown hand in the National Portrait Gallery



A Portrait of William Harvey

The artist has dwelt upon Harvey's acts and meditations and renders his impressions of the theme Harvey is portrayed with long grey hair which may well have been dark when he was younger in accordance with tradition , of thoughtful expression, of short stature, and easy graceful mien He is wearing a gown—perhaps the identical one bequeathed by him as " my velvet gowne to my lovinge friend Dr Scarburgh "—over a dress of a gentleman of the time , and standing, nearly vis-à-vis, delivering a lecture His left hand is supporting a skull , while his right is resting upon a diagram of the circulation of the blood, which he had first publicly demonstrated in a lecture, delivered on April 17th, 1616, on the Chest and its Contents

In 1647, the date which the picture bears, Harvey was about 69 years of age , he died 10 years later, in 1657 In 1646, after the surrender of Oxford during the Rebellion, Harvey returned to London and resided at his brothers' houses They were wealthy merchants There would seem nothing improbable in Harvey giving sittings to Sir Peter Lely Lely was born 1618, arrived in England in 1641 and in 1643, at the age of 25, painted portraits of Charles I , William Prince of Orange, and Princess Mary We learn also from Bryan's dictionary that among the very numerous portraits which he painted was one of Oliver Cromwell At the Restoration, Charles II appointed Lely his principal painter, and created him a baronet in 1679 or 1680 Lely was seized with apoplexy while engaged on a portrait of the Duchess of Somerset, and died in 1680

A signature is not needed to prove a picture to be genuine, even where the artist's habit was to sign A signature may be a good clue to ascription, an original signature is, of course, strong evidence of authorship, while even a false or faked signature is not definite proof against authorship, for a signature may be added to a genuine picture

The small photograph which accompanies these notes does no justice to the original, which I shall be happy to show to persons interested

---

[1] Extracts from a poem to the Incomparable Dr Harvey on his Books of the Motion of the Heart and Blood, &c The poem appeared as an introductory in Anatomical Exercitations, 1653, and is signed M LL , M D

Royal Free Hospital New Children's Wards. The Queen opened recently the new Riddell Wards for children, so named after Lord Riddell, the president of the hospital Advantage has been taken of the position at the top of the building to provide facilities for sunlight treatment Eighteen beds are available, and boys will be admitted up to 10 years of age and girls up to 12 The centenary of the hospital is to be celebrated by erecting a children's wing, to include quarters for infants' and children's clinics, a tonsil and adenoid ward, an operating theatre, and recovery rooms, and an expansion of the pathological department The cost will be £200,000

SCOTLAND.

(From our own Correspondent)

Influenza

From the returns collected and circulated by the League of Nations Health Section, it is clear that the endemic prevalence of influenza in Scotland has been reinforced by fresh infection from various countries Influenza has wandered into almost every part of Scotland. Thus there are localities in the Lowlands where a couple of families imported from England have spread influenza through a village or region, and it is this type of sudden invasion and spread that confirms a diagnosis of specificity Early in the year there was little evidence of a widespread epidemic, and even a doubt of the real nature of the disease Seasonal colds and catarrhs necessarily complicated the position But, even in special areas like Edinburgh or Glasgow the characteristic syndrome of influenza—including headache, pains in the back, slight cough, laryngitis, or gastric symptoms—were repeated too often be ignored The epidemic was reminiscent of that of 1890, but it is the universal story that the cases are mild This, of course, is one of the treacherous features of influenza ; it is most likely that there will be a group of cardiac or other disablements later in the year

No doubt, the Health Section of the League of Nations will arrange for a general report to be built up on the basis of local reports, and this ought to throw light on the European spread of the infection It may bring together data bearing on the two problems, (*a*) why the endemic infection persists, though in an ever-weakening form, and (*b*) why, in spite of the immunity to be expected from this wide diffusion, a more virulent infection suddenly stirs up fresh epidemics

Meanwhile, how is the death rate affected ? The following figures are taken from the weekly returns for the 16 large towns In 1925 there was a steady increase of deaths from influenza until the fourth week of March, when the climax was 97 per week In 1926, the numbers were relatively low until the third week of March, when they rose from 12 to 31, and by the second week of April had reached 115 By the end of May, the numbers were down to 6 In 1927, the weekly deaths have been rather more than in 1925 or 1926 They show an increase towards the end of January from 13 to 18, and in February they have worked up from 24 at the beginning to 45 at the end In the first week of March there were 62 deaths The period of heaviest incidence seems to have shifted to a later period than last year, and 1927 may repeat the incidence of 1925

Treatment of Cripples

Both in Glasgow and Edinburgh active steps are being taken to improve the treatment of cripples Recently Glasgow established an orthopædic clinic. In Edinburgh, the movement for establishing a hospital for cripples is very active, and the promoters have every hope of a cordial response to the appeal when it is launched This hospital will be an important new departure in many respects The policy of a distinct hospital has been adopted after careful discussion with the leading hospital authorities in Edinburgh. The minimum aimed at is 75 beds and the estimated cost about £75,000

Pneumonia in Glasgow

Dr. A. S M MacGregor says that pneumonia in Glasgow was slightly more prevalent in January than in December, and that its treatment formed a large part of the work in the hospitals The municipal care of pneumonia remains on the high level set a few years ago The severity of the disease was roughly normal, the case-mortality being 30 8 per cent

Careful observations of air pollution by smoke and the local incidence of fogs are still being taken, and it is hoped that definite correlations may be established between respiratory epidemics and the proportion of soot and fogs Over a generation ago the late Dr Burn Russell indicated that a day would come when health measures could do no more for the environment, and when Glasgow would suffer from its ultimate disability—namely, the fact that it is a large crowded city lying mainly in a flat and chilly river valley Perhaps that day may come, but meanwhile there is a lot to do to get the Glasgow air clearer. Dr. Russell would probably have thought many times before devoting hundreds of beds to the municipal treatment of pneumonia

The Lister Centenary

The official programme of the celebrations to be held in Glasgow on April 1st has now been issued They will begin with a service in the Cathedral at 11 15 A M , which will be attended by the Lord Provost and magistrates, and representatives of the University, the Royal Faculty of Physicians and Surgeons, and other public and scientific bodies There will previously be a procession from the Royal Infirmary to the cathedral The Rev Lauchlan MacLean Watt, Minister of Glasgow, will preach the sermon, and afterwards the Lord Provost and corporation will give a luncheon in the City Chambers The toast of the Illustrious Memory of Lord Lister will be proposed by Sir John Bland-Sutton, and at the conclusion of the luncheon those who wish to honour Lister's memory by placing flowers on his statue will proceed to the Kelvingrove Park for the purpose, leaving the City Chambers about 3 o'clock The University of Glasgow will give a reception at 8 P M. The guests will be received by the Principal who will, during the evening, deliver an address of welcome Short addresses will also be delivered by Sir Hector Cameron, Sir George Beatson, Prof Murdoch Cameron, and Prof. Irving Cameron of Toronto

In connexion with the centenary, Messrs Jackson, Wylie and Co , will publish this month a book by Sir Hector Cameron, entitled "*Reminiscences of Lister and of his Work in the Wards of the Glasgow Royal Infirmary, 1860–69,*" and also "*Lister and the Lister Ward in the Royal Infirmary of Glasgow,*" by Mr Ernest Maylard , F.R F P S, Mr James A Morris, F R I B A., and Mr L W G. Malcolm, M Sc , with an *introduction by Lord Blythswood*

Lectures and Meetings

This year two distinguished lecturers have visited Scotland—Prof A S Eddington and Prof J. S Haldane When Prof Haldane's Gifford lectures are reprinted, we shall have a full and critical statement of the guiding value of the concept of vitalism, an idea which has great significance in medicine In the flux of physical and physiological ideas, as expounded by Eddington and Haldane respectively, there is a danger that both biology and physiology may glide into the older world where *virtus dormitiva* could, without shame, be regarded as an explanation Prof. Haldane is in no such danger, but the possibility nevertheless exists

Among other lectures recently given has been a series on the Problem of Maternal Morbidity arranged by the Edinburgh Women Citizens, and delivered by Dr Charlotte A Douglas, Prof R W. Johnstone, Dr Mary Macnicol, Dr Margaret Martin, and Dr W T Benson The last of them is to be given by Prof Munro Kerr on *Maternity as it Should Be* As a form of public education in health, nothing could be better than these lectures, and there is evidence of growing interest in the problems of maternity, which are to be the subject of discussion this year at the Annual Meeting at Rothesay of the Scottish Association of Health Visitors, Women Sanitary Inspectors and School Nurses This conference also will be addressed by Prof Kerr and Prof Johnstone

---

Resignation of an Honorary Surgeon—Mr H J Godwin has resigned the position of honorary surgeon of the Hampshire County Hospital, which he has held for 23 years The annual Court of Governors has passed a resolution of thanks and regret

Correspondence.

"Audi alteram partem"

FEES FOR PATHOLOGICAL INVESTIGATION

To the Editor of THE LANCET

SIR —The British Pathologists Association was formed at a meeting held in London on Jan 7th last for the purpose of developing the application of pathology in relation to medicine and of protecting the interests of those engaged in its study and practice Membership is open to all registered medical practitioners engaged in the study and practice of pathology It is in the opinion of the Council of the Association very necessary that there should be in existence a schedule of minimal fees payable for pathological investigations for persons insured under the National Health Insurance Acts In the absence of such a schedule there is bound to be competition for this work with consequent fee-cutting and inefficient work

The Council of the Association has in hand the drafting of a schedule of fees for the various classes of laboratory investigations in general use in clinical medicine The fees in this schedule have been worked out on the basis of the cost per pair of hands per hour employed in a pathological laboratory under the direction of one of the members of the Association where the costs have been accurately controlled over a period of years The fees indicated may be regarded as the minima which can be expected to give a reasonable financial return when the procedures are performed in a laboratory subsidised from no outside source Copies of this schedule will be sent on request to all members of the Association for comment or suggested amendment It is proposed to submit this schedule to the Ministry of Health and to urge its adoption for pathological work performed for insured persons under any arrangements made either by the Ministry or by individual National Health Insurance Committees

The British Pathologists Association is working in the very closest touch with the British Medical Association from which it has received invaluable help The schedule of fees for pathological investigations is to be submitted to the Insurance Acts Committee of the British Medical Association at an early date, at a meeting at which the whole question of provision of a pathological service for panel patients will come under discussion

In approaching the Ministry of Health the British Pathologists Association wishes to be able to speak as representing the body of practising pathologists in this country Practising pathologists not already members of the Association are therefore urged to become so The annual subscription is £1 1s which includes entrance fee Medical practitioners desiring to join the Association should communicate with one of the members of the Council, which is constituted as follows Dr C Powell White (President), Victoria University, Manchester, Dr J G Greenfield, National Hospital, Queen-square, London, W C 1, Dr S C Dyke, Wolverhampton and Staffordshire Hospital, Wolverhampton, Dr A Renshaw, 16, St John-street Manchester; Dr E Wordley, South Devon and East Cornwall Hospital Plymouth, Dr G Hadfield General Hospital Bristol, Dr A. G Shera Princess Alice Memorial Hospital Eastbourne, Dr A F S Sladden General Hospital, Swansea; Dr W Grace Royal Infirmary, Chester. Dr R V Solly, Royal Devon and Exeter Hospital, Exeter

I am, Sir, yours faithfully,

S C DYKE,

Secretary, British Pathologists Association

Wolverhampton, March 10th, 1927

LEAD-SELENIUM COLLOID IN CANCER

To the Editor of THE LANCET

SIR,—I have been interested in the brief account by Dr A T Todd of the initial results obtained in some of the cases of malignant disease treated by him with "Lead-Selenium Colloid (" THE LANCET, March 12th, p. 575) The possibilities of a combination of these elements occurred to me, and doubtless to many others, long ago, and, as a matter of fact, our physical chemists had no difficulty in making an excellent colloid of lead selenide But what will ultimately prove to be the most useful preparation of lead no one can foretell at the present time Since many preparations of lead will probably be found to affect to a greater or lesser degree malignant neoplasms, what are really needed are comparative studies in regard to a large number of combinations rather than isolated observations of one particular preparation This is the line our own clinical investigations have taken I am, Sir yours faithfully,

Liverpool, March 12th, 1927 W. BLAIR BELL

THE TREATMENT OF HERNIA

To the Editor of THE LANCET.

SIR,—May I make the following observations in reply to the questions raised on the subject of the treatment of hernia by Mr Geoffrey Keynes and Mr T. P Dunhill[1] Although I have performed hernioplasty in children and healthy muscular adults, I do not consider it absolutely indicated in these cases of the oblique inguinal variety I am of opinion, however, that employment of this method shortens the convalescence and will enable the patient to undertake strong muscular exertion at an earlier date than otherwise In the case of both direct and femoral hernias hernioplasty should always be done

I have performed my flap hernioplasty in many patients over 50, with feeble muscles, and suffering from large oblique hernias Such patients belong to the class of case often refused operation by the surgeon Here hernioplasty is strongly indicated and will give most satisfactory results

As regards the second point also raised by Mr Dunhill, I am still of the opinion that Gallie and Lemesurier's technique, if accurately followed, may be improved upon, as by my method The use of stay knots and the method of joining sutures by perforating the previous strip is a complicated process and takes longer than the modification by means of the thread fixation stitch

I am, Sir, yours faithfully,

London, March 14th, 1927 ERNEST COWELL

RHEUMATISM AND MALNUTRITION

To the Editor of THE LANCET.

SIR,—I have read with much interest your summary of the Report on Heart Disease, together with the leading article upon it, and I am delighted to find therein corroboration of what I stated at the Cripples Conference last November I have pointed out that bad teeth, enlarged tonsils, damp houses may be associated with but are not the cause of rheumatic fever, whilst the one and only thing common to all these cases is malnutrition whereby they get none of the lime-bearing foods such as milk, eggs, and cheese In addition they aggravate this want of lime intake by the partaking of acids like vinegar, pickles sauces, and lemons Where two or three in a family fall a prey it is always found that their feeding habits differ from those who are not attacked This point is fully emphasised in my article on Heart Disease as a Deficiency Disease which appeared in the *Medical Press* for Sept 1st, 1926

I am Sir, yours faithfully

Swansea, March 14th 1927 G. ARBOUR STEPHENS

[1] THE LANCET, March 12th, p 568

Obituary.

FREDERICK ARMITAGE SOUTHAM,

M A. OXF., F R C S ENG.,

EMERITUS PROFESSOR OF SURGERY IN MANCHESTER UNIVERSITY

THE death of Mr F A Southam on March 9th removes one of the greatest clinical teachers that the Manchester school has yet produced as well as one of the soundest and most brilliant of operating surgeons

Frederick Southam was the son of George Southam, honorary surgeon to the Manchester Royal Infirmary from 1847 to 1876, and connected also with the Royal School of Medicine in Pine-street He was educated at Rugby and Christchurch, Oxford, where he took a first-class in Natural Science, proceeding to Manchester for his medical training and qualifying in 1876 After holding various junior appointments to the Royal Infirmary, he was elected honorary assistant surgeon in 1880, serving on the surgical staff until his retirement in 1910 at the age of 60 On the outbreak of war in 1914 he was mobilised as Lieutenant-Colonel in the 2nd Western General Hospital, and again took charge of the surgical unit at the infirmary, in order to release Colonel J W. Smith to command this hospital

[*Lafayette, Manchester*

MR F. A. SOUTHAM

Mr Southam's memory will be cherished by many generations of students who went round the wards of the Royal Infirmary with him, here his enthusiastic interest in his subject and the careful preparations made to illustrate its every aspect compelled the close attention of the whole class His teaching was delightfully clear and concise and yet sufficiently dogmatic and definite to be easily remembered However foolish an answer a student gave he never showed the slightest impatience, but would proceed quietly to criticise it in detail He held strong and decided views on most surgical subjects, and usually insisted on following his own judgment, which had a way of proving remarkably accurate As an operator he was not only brilliant and dexterous but he remained very cool and calm during the performance of the most extensive operative procedures, and it was always, writes one of his colleagues, a great surgical treat to watch him amputate at the hip by the Furneaux-Jordan method without a tourniquet He was not, perhaps, as scrupulous as some in arresting hæmorrhage, and "a little oozing" was one of his common expressions—so much so that the students were wont to say that he would make use of this expression were he to cut the aorta itself

He held many other appointments outside the infirmary, being attached to the Christie Hospital, the Cancer Pavilion and Home, the Northern Hospital for Women and Children, and the Jewish Hospital For many years he occupied the chair of clinical surgery in the University, and he examined in surgery both at Manchester and Oxford His private practice became very engrossing, but he never allowed it to interfere with his hospital duties From his earliest years Mr Southam was especially interested in the surgery of the bladder and urethra, he contributed an article on "Injuries and Diseases of the Bladder" to the Medical Encyclopædia, an Analysis of 120 operations for Vesical Calculi, and he received honourable mention for a Jacksonian Prize dissertation on Tumours of the Bladder He was the author of "Regional Surgery, a Manual for Students," and his article on "Fractures" in Treves's "Manual of Surgery," was regarded as the best description of fractures available at that time He was the first surgeon in Manchester to stand up for the interval operation in appendicitis, then being advocated by Treves

Mr Southam was of an intensely shy disposition It used to be said of him that whenever he met a student coming down the street he would, if possible, avoid meeting him, but, if not possible, he would keep his eyes downcast until just the moment of passing when he would raise them with a quiet smile Though small in stature he had an impressive personality, and was respected as well as beloved by his students and colleagues who elected him at one time or another to the presidency of all the local medical and pathological societies An old Oxford Blue in sprint racing, he kept up his interest in athletics as far as his time permitted His wife predeceased him by some years He leaves two sons, the elder of whom is vicar of St Mark's, Portsmouth, the younger, with whom he lived, being Mr A H Southam, a Hunterian lecturer at the Royal College of Surgeons of England this year

THE LATE DR. SHILLINGTON SCALES

Dr Stanley Melville sends the following appreciation of Dr Shillington Scales, an obituary notice of whom appeared in THE LANCET of March 12th

"The ever-thinning line of veterans in the field of radiology is the poorer by the passing of Francis Shillington Scales To those of us who were associated with him in training candidates for the diploma, in serving on the Special Committee at Cambridge, or in conducting the examinations, the zeal and tireless enthusiasm of the man were revealed He took no narrow academic view of the training, and to his lasting credit was his insistence upon wide clinical experience for the radiologist For this reason he kept in close touch with the Education Committee of the British Institute of Radiology in London and with the great provincial medical schools A man with a less wide outlook might have been tempted to confine the teaching to Cambridge itself, with the result that there would have been by now a multiplicity of diploma-conferring bodies in existence As it was Shillington Scales always viewed with concern anything that was likely to upset the very happy relationship that had existed from the beginning with the teachers in the metropolitan schools and with great universities, such as Manchester and Liverpool Shillington Scales was an excellent pathologist and microscopist, and he had the gift of being able to impart his knowledge to others It was always noted that the men who came to London for the final two months' clinical training had a sound knowledge of pathology He was a man of orderly mind and habit, and his system of filing and indexing was of inestimable value to him in preparing his lectures and to the *Journal of Radiology* for which he undertook to supply references to the literature Shillington Scales's post will in due course be filled, and no doubt adequately filled, but he himself will be sadly missed by many friends who had learnt to appreciate him for his kindly personality and his selfless enthusiasm in working for an ideal"

G B F Reece Royal Dental, R Rosefield, Univ Coll, J F Y Sellin, Bristol J Shwer, Royal Dental R C Smart, Manchester E N Stevens, Guy's, N R Thompson, Royal Dental, F S Tinsley, King's Coll, R G J Tovey, Royal Dental, R C Virgo, London, R W Waldie, Guy's, F A Walter Manchester T W Watts, F T Wilkinson H F J Willis, and M Wolman Guy's, A A Wood, Univ Coll, C H Woodham and N C Yendell, Guy's

The Diploma of M R C S was conferred upon Dorothy Bolton, M B Calcutta, of Calcutta and Charing Cross Hospitals

Diplomas in Tropical Medicine and Hygiene were also conferred (in conjunction with the Royal College of Physicians) upon the following 24 candidates (6 women and 18 men) who have studied at the London School of Hygiene and Tropical Medicine London and have passed the examination held by the Conjoint Board —

S Annecke, E G Anthonisz A C L O'S Bilderbeck, Catherine Y Burne, N P Dalal, T B Gilchrist, R D Gross, Kathleen M Halloran R G Keays H H W Kumm, F R Lockhart A D Loganadan, P H Martin F R L Miller Margaret M Nolan, J Portelli, Helen M Russell E G Sayers H M Shelley Viva E K Stuart H S Townsend, Bertha Williamson, C J Wylde, W A Young

University of London —Applications for grants under the Thomas Smythe Hughes Medical Research Fund should be made between May 2nd and June 15th Applications are also invited for the Laura de Saliceto Studentship for the Advancement of Cancer Research, which is of the value of £150 a year and may be held in conjunction with a physiological, pathological, or clinical appointment Candidates may be of either sex, and need not be members of the University The studentship is awarded for not less than two years Particulars of the Fund and Studentship may be had from the Academic Registrar A University Studentship in Physiology (£50 for one year) will be awarded to a suitable student or graduate of the University Applications must be received by the Principal Officer on or before May 31st

Cambridge University Medical Society An Interesting Tour —In the magazine of the Cambridge University Medical Society for the Lent Term there is published a provisional programme of a tour to be taken by the members through the laboratories hospitals and clinics of Germany, Czecho-Slovakia Austria and France The party will be escorted round the University medical schools at Hamburg, Berlin, Dresden, Prague, Vienna, Munich, Strasbourg and Paris It is proposed to leave Southampton on August 24th The time to be allotted at each centre is not yet published in the programme, but the railway tickets will be valid for 33 days The tour has been economically planned and the general amenities of the journey have been studied The cost is £45, and the booking arrangements are in the hands of Messrs W W Bell & Co 6 King's Parade, Cambridge to whom *all* questions about the route and passports should be addressed An entrance fee of £2, £3, or £4 is payable, according as to whether entry is made on the first day of April, the first day of June, or later, while no applications will be considered after July 14th, the first £2 of the entrance fee counts as part of the fare These details should be borne in mind by those who propose to join the tour, as, in order to secure reduced railway fares, all *tickets for the party must be issued at the same time*, and members if they withdraw after the tickets have been issued, may forfeit the cost The tour is open to ladies as well as to honorary members in the Cambridge University Medical Society

Fellowship of Medicine and Post-Graduate Medical Association —On Thursday, March 24th, at 5 P M, Dr R Travers Smith will lecture at the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, on Emergencies in Neurological Practice On Tuesday, March 22nd, at 2 P.M, Mr N C Lake will give a clinical demonstration in surgery at Charing Cross Hospital, and at 4 P M on March 23rd and the two following days Mr Levy, Miss Mann, and Mr Williamson-Noble will give special demonstrations in ophthalmology at the Central London Ophthalmic Hospital The lectures and demonstrations are free to members of the medical profession An all-day comprehensive course in Orthopædics, lasting until April 2nd is in progress at the Royal National Orthopædic Hospital A two weeks course was begun on March 21st at the London Temperance Hospital for the benefit primarily of the general practitioner (4 30-6 P M) From March 28th to April 9th the Queen's Hospital will hold a special course in Diseases of Children, instruction at this hospital being chiefly clinical The Royal Eye Hospital will undertake a series of afternoon demonstrations on the Diagnosis and Treatment of Diseases of the Eye from March 28th to April 8th The Fellowship arranges for practical courses in anæsthetics and obstetrics, and *also* makes arrangements for clinical assistantships in gynæcology Copies of all syllabuses and of the *Post-Graduate Medical Journal* are obtainable from the Secretary of the Fellowship, at 1, Wimpole street, London, W 1

Royal Faculty of Physicians and Surgeons of Glasgow —*At the monthly meeting of the* Faculty held on March 7th, Dr Herbert Frederick Blacklee was admitted (after examination) as a Fellow of Faculty

Royal Microscopical Society —The Conference at Liverpool originally arranged for the third week in March has been postponed till March 29th, 30th, and 31st, owing to difficulty in securing hotel accommodation

Hunterian Society —The third dinner meeting of this society will be held at Simpson's Restaurant 2 and 3, Bird-in-Hand Court, 77, Poultry, Cheapside, on Monday, March 21st at 7 30 P M A discussion on the Bottle of Medicine will be opened by Dr L G Glover and Dr Thomson Brown

Royal Sanitary Institute —A sessional meeting will be held on Friday, March 25th at 5 P M, in the Town Hall Leeds, when a discussion on Cancer will be opened by Sir Berkeley Moynihan, followed by Prof R D Passey, Director of Cancer Research, University of Leeds The chair will be taken by Dr G F Buchan

University of Manchester —Prof H S Raper has been appointed dean of the medical school as from July next Mr P W Clutterbuck has been appointed assistant lecturer in physiological chemistry, Mr E N Willmer assistant lecturer in comparative physiology and Dr Eugenia R A Cooper assistant lecturer in anatomy The Hill Prize in biochemistry has been awarded to Mr Eric Boyland

Medico-Legal Society —A meeting of this Society will be held at 11 Chandos-street Cavendish-square, W 1 on Thursday, March 24th, at 8 30 P M, when *Sir Bernard Spilsbury will show a Hat* from a Fatal Case of Shooting and give a short communication thereon Dr Letitia Fairfield, C B E, will read a paper entitled Some Psychological Reactions *of the Physiological Crises in* Women, and a discussion will follow Members may introduce guests on production of a Member's private card

Listerian Society King's College Hospital London —The centenary celebrations of the hospital in connexion with Lister are to be held on April 4th, and will take the form of addresses by house surgeons and dressers who worked under the great discoverer, the subject being the Personality of Lord Lister These include Sir Watson Cheyne Major-General G Carleton Jones, Sir Lenthal Cheatle, Dr L V Cargill, Dr Allan Macnab, Dr H Distin, Dr H Perry, Dr R A. Gibbons, and Dr A Bousfield Mr Hamilton Russell of Melbourne may also be present The proceedings will start at 8 and end at 10 P M. There will be refreshments, and the St Thomas's Hospital Band will assist in the proceedings

The Central London Ophthalmic Hospital Medical School —A pleasant dinner of the past and present students was held at the Langham Hotel on Friday, March 11th, Mr Ernest Clarke in the chair The toast of the hospital and school was proposed by the Chairman, who traced the growth of the hospital since the early days when he was elected *to the staff* This *was felicitously replied to, for* the hospital by Mr C M Wilkin, Chairman of the Board of Management Mr F A Williamson-Noble, the Dean replied for the school and gave an interesting account of its spreading activities Mr Stephen Mayou proposed the health of the visitors which was replied to by Sir John Parsons, and Mr A A Levy proposed the Chairman's health

Conference on Tuberculosis —The Tuberculosis Society and Society of Superintendents of Tuberculosis Institutions are holding a joint provincial meeting at Oxford from April 7th to 9th The meetings will be held in the Pathological Lecture Theatre On Thursday, *at* 2 30 P M., Prof Lyle Cummins will read a paper on the Bovine Tubercle Bacillus in Immunisation, a discussion will *follow. At* 10 A M on Friday Dr Leonard Hill will open a discussion on the Defensive Mechanism of the Body against Tuberculosis from the Physical and Chemical *Aspect*, Mr G R Girdlestone and Dr E Obermer will read papers dealing with the same subject On Friday, *at* 2 15 P M, *Dr* John Freeman will speak on the Defence of the Body from the *Bacteriological* and Immunological Side He will be followed *by Dr A G* Gibson on Secondary Infections in relation to the Progress of Pulmonary Tuberculosis and Dr A D *Gardner on the Laboratory Diagnosis* of Tubercle On Saturday at 10 A M, Dr J Middleton Martin, Dr D P. Sutherland, and Dr Peter Edwards will discuss the Gaps and Flaws in the Public Health *Administration* of Tuberculosis On Saturday *afternoon* members are invited to visit the Wingfield Orthopædic Hospital and the Osler Pavilion Accommodation will be available for both sexes at Somerville College, at an inclusive charge of £2 for the period of the meeting, or pro rata Those wishing to be present are asked to communicate as early as possible with Dr F J Blackmore the Tuberculosis Dispensary, Maxey Road, Plumstead, S E 18

THE PENALISATION OF THE TUBERCULOUS

To the Editor of The Lancet

Sir,—An assistant in a good sanatorium applied for a similar post in a county sanatorium where there is a pension scheme He had an interrupted undergraduate career through a breakdown with pulmonary tuberculosis He made a good recovery and was advised to take up sanatorium work He secured a place in a sanatorium where research work is done, and he was never one day off duty He wished to advance and his chief strongly advised him to approach other sanatoria, and he applied for another post He got on the list at once, when he was specifically asked why there had been a break in his studies, and made no concealment But he was told that he ought to have announced this in his application, for then "they would not have bothered about him"

The applicant is a friend of mine, and said that he did not mind losing the post, being in a better sanatorium, though on less pay, but he resented the attitude displayed towards him

Can nothing be done to prevent this penalisation of those who have been tuberculous ?

I am, Sir yours faithfully,

March 15th, 1927 M O

CAN TAR CAUSE PULMONARY CANCER?

To the Editor of The Lancet

Sir —I was greatly interested by your note under the above heading on p 582 of last week's issue I think it is generally admitted that pulmonary cancer has become much commoner in late years and I have sometimes wondered whether this may not be due to the inhalation of dust from tarred roads

I am, Sir, yours faithfully,

Robert Hutchison

Devonshire place, W, March 14th, 1927

THE IMMEDIATE TREATMENT OF THE SEVERELY INJURED

To the Editor of The Lancet

Sir,—Accidents, especially those caused by rapidly moving traffic, are on the increase Every year a number of these patients are brought to hospitals either dead or in a dying condition A further number are taken to their own houses or to nursing homes in a similar condition

This irrational performance is likely to continue until it is generally recognised that a person, when injured so severely as to be nearly dead, is not in a fit state to be carried any distance, no matter what his destination, and that a journey of any length, for a patient who is only just alive, is the most certain method of obliterating his already small chance of survival

The desperately injured man, if he is in a building where he can be kept warm and at rest, should be kept and treated where he is until he has rallied If he is in the open and exposed to wind and weather, he should be taken to the nearest available place of shelter and treated there until he is fit to stand the longer journey

Those responsible for ordering and carrying out the transport, over long distances, of the severely injured who are nearly dead, the ordering of "immediate removal to hospital," so often appearing in the newspapers, are chiefly medical men, police officers, and ambulance workers In justice to the two latter, it should be remembered that, very often, they are only carrying out the orders of the doctor who has been called to the case

First-aid and ambulance lecturers can help by teaching their pupils the folly of carrying long distances patients who, as the result of an accident, are nearly dead But reform, in the immediate treatment of the severely injured, to be effective, must begin in the practice of doctors Example is better than precept

I am, Sir, yours faithfully,

Plymouth, March 5th, 1927 C Hamilton Whiteford

Medical News.

University of Oxford —At a recent congregation the following degrees were conferred —

D M —V S Hodson

B M —D A Robertson, C S Broadbent, and M D Bower

The *Sir William Dunn School of Pathology* was handed over to the Vice-Chancellor of the University by Mr C D Seligman, on March 11th, in the presence of a representative gathering The building, of which we published a picture last week, has in the basement a low-pressure chamber large enough to enable physiological and pathological observations to be made on the effect of altitude on men. A departmental library will occupy part of the ground floor, the rest of the building being devoted to laboratories for teaching, and research animal rooms Accommodation and equipment for some 50 undergraduates and 25 research students is provided

The *Rolleston Memorial Prize*, which is now of the value of about £100, is awarded every two years, under the conditions stated below, for original research in animal or vegetable morphology, in physiology and pathology, or in anthropology No candidate will be eligible (1) who has not either passed the examinations for the B A or B M degree at Oxford, or for the B A or M B degree at Cambridge, or been admitted as an advanced student, or as a student for the degree of B Litt or B Sc at Oxford or as a research student for the degree of M Litt or M Sc or Ph D at Cambridge, (2) who has exceeded a period of six years from attaining one or other of these qualifications, or from attaining the first of such qualifications if he has attained more than one, (3) who has exceeded ten years from his matriculation The next award will be made in Trinity Term, 1928 Candidates must forward their memoirs to the Registrar of the University before March 31st, 1928

University of Cambridge —At recent congregations the following degrees have been conferred —

M D —W N Goldsmith

M B and B Chir —B E Ahrens W A Bourne, J C P Grey, H E Nourse, W H Palmer, G Simon, and D G Shields

M B —R W Cuningham

B Chir —R W B Ellis, H J Heathcote, W L Roberts, F C Roles, and H L Wilson

Royal College of Surgeons of England —At a meeting of the Council of the Royal College of Surgeons on March 10th, Sir Berkeley Moynihan, President, in the chair, the following were elected Honorary Fellows subject to their personal attendance at the College —R Alessandri, Professor of Surgery, Rome University, E W Archibald, M D, Professor of Surgery and Clinical Surgery, McGill University, F. A B Krogius, Professor of Clinical Surgery, University of Helsingfors, P Lecene, Professor of Surgical Pathology, University of Paris, R Leriche, Professor of Clinical Surgery, University of Strasbourg, R Matas, M D, LL D, Professor of Surgery, Tulane University of Lousiana, New Orleans, and C Willems, Professor of Operative Medicine, University of Liege Sir Holburt Waring was re-elected as the representative of the college in the General Council Mr Victor Bonney was elected as the representative of the College on the Central Midwives Board Mr, V Warren Low, C B, was re-elected as the representative of the College on the Senate of the University of London. Dr Geo Parker, M R C S, was elected Thomas Vicary Lecturer for the ensuing year A report was received from the Committee which had had under consideration the Resolution carried at the Annual Meeting of Fellows and Members in November last regarding the question of admitting Members to direct representation upon the Council of the College A recommendation from the Committee that the views of the Fellows be ascertained was adopted, and the exact form of question to be put to the Fellows will be settled at a future meeting of the Council

Licences to practise dentistry were conferred upon the following 56 candidates (54 men and 2 women), who have passed the requisite examinations and have complied with the by-laws —

I Ackers and F J Ardouin, Royal Dental, L F Balding, C H Bandy, G H Billison, and J D Bowling, Guy's, B Braude and P B Campion Royal Dental R L Cautley, Guy's, A H Chanoch Royal Dental S I Cohen W A Corry, A C Davies R L Duchesne, and T G Emberson, Guy's, S Feitelberg and H E Glover, Royal Dental, A E Grace, Guy's, G R Hall, King's Coll, V L L Hall and J H F Hilton, Guy's, Doris M Hobbs Royal Dental, G J Hollis Guy's, H Hopson, Liverpool, A S Jones, London F W Jones, Royal Dental, C S Laurens, Guy's B Lieb and S Lizerbrum, Royal Dental, G F H McCormick, M R.C S, M R C P, Univ Coll, G N Manley, Royal Dental, H E B Mash, King's Coll, A. L Murray, Royal Dental, W H G North Guy's Frances E Osborne Royal Dental, E A Page, London, F R Phillips and

Meckel's diverticulum was the unclosed part of the omphalomesenteric duct, whilst the pouch of Rathke usually vanished completely in a few years Alternatively, diverticula might develop and in normal circumstances disappear in fœtal life. Sometimes this atrophy and disappearance might not take place, so that in adults the diverticulum persisted. Diverticula from the stomach, duodenum, and jejunum were frequently found in the fœtus and showed little masses of cells at their extremities, identical with the cells from which the pancreas arose It seemed that a whole series of efforts were made by the organism to develop the pancreas, the only ones which survived being those connected with the ducts of Wirsung and Santorini Diverticula were classified as (1) Those which arose as a bud from the wall of the intestine during development and contained all the coats of the bowel at that point, these were spoken of as congenital in origin and true in structure (2) Those occurring after development was complete, as a result of some abnormal process, these never contained all the intestinal coats and were called acquired and false (3) Pulsion or traction diverticula A traction-pulsion variety also occurred. The changes which might take place in a diverticulum were inflammation in and around the sac, suppuration, sloughing and gangrene, perforation, formations of adhesions, carcinomatous change, and rotation of the sac

Diverticulosis, he thought, was much more frequent than had been supposed, but often it did not require surgical intervention He did not believe in giving these subjects food which left little residue, they should take as much paraffin as they could stand, and have a weekly clearance of the bowel by taking a large dose of aperient Sir D'Arcy Power proposed, and Sir William Willcox seconded, a vote of thanks to Sir Berkeley Moynihan

Glasgow Samaritan Hospital—Lady Blythswood has opened a new wing of the Royal Samaritan Hospital for Women. The building and its equipment have cost £80,000, £78,000 of which was raised by a bazaar held in 1924

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED MARCH 5TH, 1927.

Notifications—The following cases of infectious disease were notified during the week—Small-pox 529 (last week 438), scarlet fever 1178, diphtheria 1006, scarlet fever 31, pneumonia 3375 (last week 3828), puerperal fever 35, puerperal pyrexia 115, cerebrospinal fever 12, acute poliomyelitis 17, acute polio-encephalitis 4, encephalitis lethargica 49, continued fever 1, dysentery 6, ophthalmia neonatorum 109 No cases of cholera, plague or typhus fever was notified during the week

Of the cases of small-pox 96 were reported from Wales, 1 only from Glamorgan, the remainder from various parts of Monmouth, with heaviest incidence on the town of Abersychan. The 128 cases from the West Riding of Yorkshire were reported chiefly from Sheffield 28, Conisbrough 28, Swinton 14, Mexborough 11, and Doncaster 9 The county of Lancaster was free During the week ended March 12th, further cases of small-pox were notified from the mining valleys of Monmouthshire, bringing the total number discovered up to close on 270 There is, however, no extension of the area of the outbreak A fourth definite case of small-pox has occurred in Newport The proposal to use Usk Prison as a temporary small-pox hospital has met with much opposition from the inhabitants of Usk and the farmers using the market in that town The prison, however, has been acquired, but will not be used unless it is absolutely necessary No further cases have been reported from the County of Glamorgan

Deaths—In the aggregate of great towns including London there were no deaths from small-pox 2 (0) from enteric fever, 73 (0) from measles, 5 (1) from scarlet fever, 216 (28) from whooping-cough, 62 (16) from diphtheria, 53 (9) from diarrhœa and enteritis under two years, and 898 (69) from influenza The figures in parentheses are those for London itself. The influenzal deaths for the week ended Mar 12th show a further substantial diminution, both in London and in the great towns generally, the figures being 105 Great Towns 572, London 49, Liverpool 22, Manchester 58, Birmingham 33, Sheffield 28, Bolton 22, and Stoke-on-Trent 21

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

Sale of Food and Drugs Bill.

The Sale of Food and Drugs Bill which has been introduced into the House of Commons by Mr Jacob was considered by Standing Committee A on Tuesday, March 8th. Mr Short was in the chair Clause 1 provides that—

> "Where any Regulations made under the Public Health (Regulations as to Food) Act, 1907, prescribe the compositions of any article of food or drink or prohibit or restrict the addition of any preservative or other ingredient or material to any such article, such Regulations shall be deemed for the purposes of the Sale of Food and Drugs Acts, 1875 to 1907, to define the nature, substance and quality of the article as regards the presence or amount of any ingredient or material specified in the Regulations and to determine whether the addition of any such ingredient or material, and, if so, what amount thereof renders the article injurious to health."

Sir Kingsley Wood (Parliamentary Secretary to the Ministry of Health) moved an amendment designed to make it clear that the Public Health Acts of 1875 and 1896 were incorporated in this measure. The amendment was agreed to Sir Kingsley Wood moved another amendment to provide that the regulations should be conclusive, not merely in regard to the presence or amount of such added ingredients as were referred to earlier in the Bill—that was preservatives or colouring matter—but also in so far as they dealt with this point in regard to natural constituents as well The Minister of Health was advised, he said, that he had no power to prescribe standards for foods generally by regulations under the Act of 1907, and therefore without any further statutory authority no article other than dried or condensed milk could be affected by this particular amendment The amendment was agreed to A further Government amendment was also agreed to, the purpose of which was to save the local authorities from having to prove that the presence of a forbidden preservative, or the excessive amount of restricted preservative, was injurious to health. This amendment fixes a standard as designed in the Bill The Committee stage of the Bill was completed and it was ordered to be reported to the House

Midwives and Maternity Homes (Scotland) Bill.

The Midwives and Maternity Homes (Scotland) Bill, presented in the House of Commons by Mr Barclay-Harvey, supported by Sir G Berry, Lt-Col. Fremantle and others is a measure designed to extend to Scotland the chief provisions of the Act which was passed last year for the control of midwives and maternity homes in England.

Mental Deficiency Bill.

The text of the Mental Deficiency Bill, which has been introduced in the House of Commons by Mr Crompton Wood, has now been issued In a memorandum attached it is explained that the main object of the Bill is to amend the definition of defectives which are contained in the Mental Deficiency Act, 1913 Under these definitions only persons who were mentally defective from birth or from an early age come within the Act, and there is thus no power to deal with cases where the defectiveness arises at a later stage. An illustration is afforded by the disease known as encephalitis lethargica, though these particularly need the sort of care and treatment which can be provided in a mental deficiency colony The effect of the Bill (Clause 1) is to eliminate the words "from birth or from an early age" and to bring within the scope of the Act all cases of mental deficiency which arise before the age of 18, whether due to inherent causes or induced by disease or injury Under the existing Act a defective may be placed under care if he is found to be also "neglected, abandoned, or without visible means of support or cruelly treated." Clause 2 (1) of the Bill extends this provision to a case where the care or training which the defective requires cannot be provided in his own home. *Subsections* (2) and (3) of Clause 2 are designed to provide that any case may be dealt with by any one of the three methods recognised by the Act—viz., providing supervision, placing under guardianship, or sending to an institution, while Clause 3 merely introduces a drafting amendment into the Act of 1913 to make it clear *that Section 4 of that Act* only applies to the two latter of these methods Clause 4 will enable an order to be made on a petition without the consent of the parent or guardian, if owing to his being abroad the attempt to obtain it would unduly delay the proceedings on the petition Clause 5 provides that if a patient is away from an institution on leave of absence he need not be brought back to the institution for examination in connexion with the continuation report required under Section 11 of the Act. Clause 6 makes explicit the power and duty of local

Manchester Students and Hospitals —In spite of bad weather, Manchester students on Shrove Tuesday succeeded in collecting £12,937 for local hospitals

Brighton County Borough Mental Hospital — On March 12th the new electrical installation was inaugurated at this institution at Hayward's Heath by Sir Frederick Willis, Chairman of the Board of Control

British College of Nurses.—This College, which has been endowed with £100,000 by an anonymous donor, has secured 39, Portland-place, London, W 1, as its headquarters The College and its governing body are composed entirely of registered nurses, whose object is stated to be to raise the standard of post-graduate nursing education and secure the economic stability of the nursing profession

London Traffic Deaths —The Ministry of Transport has convened a conference to be held on March 21st to consider what steps can be taken to reduce the number of street accidents in the metropolis During 1926 no fewer than 1020 persons were killed in street accidents in the Greater London area, while 47,213 were injured During the last six years the number of fatal accidents due to street traffic has increased by 55 per cent. and the number of injuries has increased by 125 per cent

Ireland and the Royal Army Medical Corps — Some uneasiness was caused a few weeks ago, writes our Irish correspondent, by an announcement about admissions to the R A M C It was stated that a certain number of commissions would be given on the nomination of universities and medical schools, and a list of the universities and schools to which was given the privilege of nomination was appended In the Irish Free State only the University of Dublin was given this privilege, and neither the National University of Ireland (with its three schools at Dublin, Cork, and Galway), nor the Royal College of Surgeons in Ireland was mentioned As both these bodies have contributed very largely in the past to the personnel of the Royal Army Medical Corps, their omission from the list of nominating authorities gave rise to some uneasiness lest their graduates and licentiates should be at a disadvantage in the future The matter was taken up with the Director-General of the R A M C. by the British Medical Association, at the request of its Irish Branch, and assurances have been given that the nomination of graduates or licentiates from any of the Irish schools will be considered on equal terms in the future

University of London Animal Welfare Society. At a meeting of this Society held at University College on March 10th, Sir Arthur Mayo-Robson in the chair, a lecture entitled Animal Welfare from the Point of View of the Veterinary Profession was given by Prof F T G Hobday. The Chairman said that as a nation we prided ourselves on being humane, but so long as we permitted the painful slaughter of 40,000 beasts in England every working day, when, by simple and certain methods they could be rendered unconscious before slaughter, he feared that we could not honestly claim to be the most humane nation, since Holland, Switzerland, Sweden, Germany and other countries legislated for compulsory humane slaughter So long as the Ministry of Health's by-law was only permissive it would never be universally adopted, and it entirely depended on the public whether it was made compulsory He considered that the work of the Society was well worth the attention of educated men Prof Hobday said that members of the veterinary profession could do much to help the Society in its first aim—namely, "to disseminate a knowledge of the needs of animals" The second aim, "to initiate a movement which shall extend to Continental and other universities," was especially well thought out, for in certain of the continental countries animals were not always well cared for, and a movement initiated through the universities would attack the problem at the educational fountain-head After cordially welcoming the advent of the woman veterinarian, Prof Hobday dealt with faulty feeding and housing, unreasonable chaining of dogs, and cruel methods of destroying vermin, such as rats, mice, and rabbits, he exhibited the humane snare recommended, for want of a better, by the Royal Society for the Prevention of Cruelty to Animals As regards humane slaughtering, though the pole-axe and the hammer produced instantaneous unconsciousness when the blow was effective, the humane killer was far easier to use For destroying small animals electrocution or the lethal chamber should be used, preceded in the case of the dog by a dose of morphia. New regulations had recently been made by the Ministry of Agriculture with regard to the importation of animals by sea, and it was to be hoped that they would be as successful as those by which the shameful export of decrepit horses had been brought to an end Speaking of free veterinary clinics for the poor, Prof Hobday claimed that the animals of the poor were entitled to skilled diagnosis and treatment, and should not be left to the amateur without professional training

An Industrial Experiment with Vitaglass — Messrs Ferranti, Ltd, electrical engineers, have had about 33,000 square feet of Vitaglass put into the windows and skylights of a new extension of their works at Hollinwood, near Manchester About a third of the 400 workers on the two floors thus fitted are under 21 years of age It is hoped that after a year's experience it may be possible to compare the efficiency and sickness-rates of these employees with those of workers in the old building

The Hygiene of Married Life and Parenthood —A course of lectures is being given at Carnegie House, 117, Piccadilly, London, W 1, on Wednesdays at 8 30 p m. The next lecture will be given on March 23rd by Mr. Leonard Phillips, who will deal with the Hygiene of Pregnancy The subjects of the remaining lectures will be the Pros and Cons of Contraception, by Dr Eric Pritchard (March 30th), Problems affecting Husbands and Wives as Fathers and Mothers, by Dr J A. Hadfield (April 6th), and the Foundations of Happy Parenthood, by Dr Flora Shepherd (April 13th) Tickets may be had from the Secretary of the National Association for the Prevention of Infant Mortality, Carnegie House

India and the General Medical Council — On Feb 17th the Delhi Medical Association entertained Sir Norman Walker, who is visiting India on behalf of the General Medical Council of Great Britain Dr J K Sen, the President, took the chair In the course of his address Sir Norman Walker said that the Council was neither a legislative body nor a trade-union Its sole aim was the welfare of the public which it guarded by keeping a register of those who acquired a certain standard of skill in diagnosis and treatment. The Council in no way interfered with the Universities by laying down a definite course or framing a curriculum, but provided against the unfit by supervision of examination and by fixing the age of the candidates Nothing was done to weaken the control of the Universities, and friendly rivalry among the various Universities was maintained The Universities would be well advised to leave off ploughing lonely furrows and concentrate more upon coöperation and coördination. In reply to Col H A Gidney, who discussed the question of establishing an Indian Medical Council, Sir Norman Walker referred to Part II of the Medical Act of 1886, which laid down that the King in Council might extend the Act to apply to any British Possession or foreign country The procedure was for that country, or its universities, to apply through the General Medical Council In India, the formation of such a body would be welcome if only to facilitate the work of the General Medical Council. Dr A. C Sen appealed to Sir Norman Walker to assist in establishing a General Medical Council in India, which alone could tackle problems such as research into indigenous drugs, preparation of an Indian pharmacopœia, legislation for standardisation of pharmaceutical and biological preparations, prohibition of unqualified medical practice, revision of the medical curriculum, and employment of independent medical men in Government hospitals

At the dinner which followed, Dr Bazaz proposed the toast of the Guests, and Dr S P Shroff the toast of Success to the Medical Profession The last toast was the Delhi Medical Association, given by Dr Hari Ram. Colonel Gidney, replying for the guests, laid stress on the Anglo Indian being regarded as Indian first, and deplored the persistence of such anomalies as those connected with the posts of subassistant and assistant surgeon, and the privileges of the Indian Medical Service and Royal Army Medical Corps Dr Rama Rao, who followed, referred to his Indian Medical Education Bill and its poor prospects of success unless it were supported by Government He hoped to enlist support by removing certain clauses from the Bill

The proceedings ended with a vote of thanks to the chair by Dr H Sen

Harveian Society —At a meeting of this Society on March 10th, Dr E Le Fevre Payne, the President, in the chair, Sir Berkeley Moynihan delivered the Harveian Lecture for 1927, on Diverticula of the Alimentary Canal The lecture was illustrated by photographs and skiagrams The Oxford Dictionary, said Sir Berkeley Moynihan, defined a diverticulum as "a little wayside house of ill-fame," a title which was well deserved In the alimentary canal it was due to protrusion of the mucous membrane from the lumen of the bowel, the other coats might or might not participate Budding from the intestinal wall was an essential step in the formation of various organs Examples of diverticula were (1) the pancreas, which maintained connexion with the alimentary canal through its ducts, (2) the appendix which had no differentiation into a duct, and (3) the thyroid which was a ductless gland The foramen cæcum on the dorsum of the tongue was the only patent part of this diverticulum Diverticula might develop normally in fœtal life but their connexion with the gut in the adult might be curtailed or disappear Thus

Service or not. That was absolutely wrong The medical service in the Navy was a great service and the men in it were as able as could be found anywhere but it should not rest with one man to decide in a matter of life and death of this kind No man was infallible not even a doctor and if a man was going to be thrown out he should have the right to go before a Board. He suggested that if they had a Fleet Surgeon a civil practitioner and a man like the Town Clerk of Portsmouth and those gentlemen would give their services for nothing the Navy would be absolutely satisfied to abide by their decisions 196 men were thrown out of the Service this year for tuberculosis alone. Only 6 of them or about 3 per cent were given any pension for the illness they had contracted in His Majesty's Service Men suffering from tuberculosis dare not go sick, because if they did they knew that the Fleet Surgeon would throw them out on the beach That was a wicked thing for any Government to do He urged that these men should be allowed to appeal to the Board of Admiralty Such an appeal should be made automatic and a matter of right

Lt-Col HEADLAM (Parliamentary Secretary to the Admiralty) replying to Sir B Falle said that everybody who knew anything about the subject must sympathise most profoundly with the point of view which the hon Member had put forward He doubted very much whether they could get other medical opinion quite so easily as Sir B Falle seemed to imagine No one who had had anything to do with medical boards or medical officers generally would think that they were going to change their views so rapidly as the hon Member seemed to think Whether or not an automatic appeal to the Board of Admiralty would help the men he rather doubted but if Sir B Falle would let him know of a definite case where men had been hindered from appealing to the Admiralty the matter should be looked into

The motion was agreed to

Veterinary Work in Colonies and Protectorates

Mr RAMSDEN asked the Secretary of State for the Colonies what sums had been expended from crown colony and other funds in obtaining expert advice with regard to veterinary matters affecting the crown colonies protectorates, and mandated territories —Mr AMERY replied I assume that my hon friend does not refer to expenditure on the maintenance of Veterinary Departments and their staffs or to such expert advice as is given in the ordinary course of their work by the Imperial Bureau of Entomology or by the Bureau of Hygiene and Tropical Diseases in its Veterinary Bulletin" but to special expert advice A grant of £10,000 has been made from the Empire Marketing Fund for the purpose of carrying out an investigation into the mineral content of natural pastures in Kenya, acting under the advice of Dr J B Orr of the Rowett Research Institute. It is not possible to state how much of this sum will actually be expended in Kenya At the request of the Nigerian Government Dr P J du Toit Deputy Director of Veterinary Education and Research in the Union of South Africa visited the Colony in January last to investigate mineral deficiency in pastures and to report generally on local Veterinary matters The cost to Nigeria of the visit was approximately £450

The Tuberculosis Order 1925

Mr BUXTON asked the Minister of Agriculture the number of cows slaughtered under the Tuberculosis Order, 1925 since the Order came into force and the amount spent in compensation —Mr GUINNESS replied From Sept 1st 1925 to Dec 31st 1926 23 369 cows were slaughtered by Local Authorities under the Tuberculosis Order 1925, for which compensation amounting to £90,184 was paid

Chester-le-Street Guardians and Public Funds

Sir WILLIAM DAVISON asked the Minister of Health whether his attention had been called to the misappropriation of public funds by the board of guardians of Chester-le-Street Durham during the coal strike whether he had taken legal opinion as to whether the persons concerned were guilty of having entered into an illegal conspiracy and what action the Ministry were taking in the matter —Sir KINGSLEY WOOD replied Yes Sir my right hon friend does propose to draw the attention of the Director of Public Prosecutions to this matter

Treatment of Flour with Chemical Substances

Rear-Admiral BEAMISH asked the Minister of Health whether he proposed, by legislation or otherwise to carry into effect the recommendations or any of them, of the departmental committee on the treatment of flour with chemical substances.—Sir KINGSLEY WOOD replied The report of the departmental committee is at present under consideration and my right hon friend is not yet in a position to make any statement as to the action to be taken their recommendations

Pupils in Certified Special Schools

Mr ROBERT MORRISON asked the President of the Board of Education the number of pupils in certified special schools for the blind, deaf mentally defective physically defective, and epileptic children in each of the age groups 13–14, 14–15 15–16 and over 16 respectively on March 31st 1926 Lord E PERCY replied The following is the information asked for —

Type	13–14	14–15	15–16	16 and over
Blind	613	361	288	54
Deaf	496	480	416	71
Mentally defective	2629	2103	1465	241
Physically defective	2486	1360	770	100
Epileptic	96	96	76	13

Night Work in Bakeries

Mr WILLIAM THORNE asked the Home Secretary if his attention had been called to the statement made by the coroner at the inquest on a baker who died at Sunninghill, Berkshire in connection with the deceased having worked 14 to 15 hours for six nights per week if he was aware that a two-thirds majority was secured in favour of the abolition of night work in bakeries by the League of Nations Geneva Conference, and whether it was the intention of the Government to ratify the Geneva decision.—Captain HACKING Under Secretary to the Home Office replied My right hon friend has not seen the statement of the coroner, but since his attention was called to the case by the hon Member's question he has made some inquiries So far as I have been able to ascertain it appears to have been the case that the man was being employed for excessively long hours and at a time when he was in an advanced stage of tuberculosis My right hon. friend regrets that there is no action which he can take in the matter The long hours would not have been prevented by the ratification of the Night Baking Convention the effect of which is only to prevent employment during a certain period of the night, and my right hon. friend has already explained on previous occasions why the Government do not see their way to ratify the Convention which their representatives voted against at Geneva

TUESDAY MARCH 15TH

Manufacture of Poison Gas in Russia

Sir ALFRED KNOX asked the Secretary of State for War whether he was aware that several factories were being operated by the Soviet Government in Russia for the manufacture of poison gas and the number and location of such factories and the present and potential output —Sir L WORTHINGTON-EVANS replied His Majesty's Government has information that the study of gas warfare is being actively pursued in Soviet Russia numerous factories have been set up and are in course of erection, which are or will be capable of poison gas production on a very considerable scale It is not considered that any useful purpose will be served by detailing the number and location of such factories, or by indicating their present and potential output but there is no doubt that the Soviet military authorities are actively studying this type of warfare and making preparations on a large scale for its possible eventual use

Miners Nystagmus

Mr SHORT asked the Secretary for Mines what was the number of cases of miners' nystagmus during 1925 and 1926, respectively whether the incidence of this disease was still heavy and what action, if any he proposed to take —Colonel LANE FOX replied In 1925 the number of new cases in which compensation was paid was 3444 and the number continued from previous years was 7890 The figures for 1926 are not yet available. The Mining Association and the Miners' Federation have been invited to coöperate with the Home Office to give effect to the recommendation of the Nystagmus Committee, and continual efforts are being made to improve lighting in mines

Outbreak of Anthrax at the Zoological Gardens

Sir WILLIAM DAVISON asked the Minister of Agriculture whether, in view of the recent outbreak of anthrax at the Zoological Gardens in London he would consider the advisability of extending the present Contagious Diseases of Animals Order so as to include all animals in the United Kingdom wild as well as domesticated —Mr GUINNESS replied Yes, Sir, I am at present considering the advisability of including within the scope of the Anthrax Order of 1910 all animals susceptible to anthrax which are kept in public or private zoological collections and travelling menageries authorities to provide suitable training for mental defectives whilst under supervision as well as in institutions Although the Act authorises the combination of local authorities, it does not enable a local authority to provide additional beds which could be lent to other authorities Clause 7 (1) provides for such a procedure Clause 7 (2) enables the local mental deficiency authority and the local education authority (who have responsibility for certain classes of defectives of school age) to provide an institution jointly

HOUSE OF COMMONS

WEDNESDAY, MARCH 9TH

Duties on Imported Drugs

Mr FENBY asked the President of the Board of Trade why the exemption orders applied for since last August under Section 10 (5) of the Finance Act 1926, in respect of phenacetin, phenazone, oxalic acid, hydroquinone, and other products liable to duty under Part I of the Safeguarding of Industries Act, 1921, had not yet been issued, and if he was aware that the effect of the undue delay in issuing the exemption orders was that users were compelled to pay at least one-third more than would otherwise be the case for these materials, which had to be imported as they were not made here —Sir BURTON CHADWICK (Parliamentary Secretary to the Board of Trade) replied An order under Section 10 (5) of the Finance Act, 1926, exempting certain articles from duty, was made by the Treasury on Monday last

THURSDAY, MARCH 10TH

Surgical Opinion and Light Metal Limbs

Major HILLS asked the Minister of Pensions whether, seeing that surgical opinion was overwhelmingly in favour of light metal limbs, whether for amputations above or below the knee, it was the practice of the Ministry to issue such light metal limbs in all cases of amputation below the knee or only in special cases, and if the latter, on what principle was a distinction made —Major TRYON replied I am not aware of any authority for the assumption made by my hon and gallant friend in the first part of the question, but I may say that light metal limbs are issued both for above and below knee amputations in every case recommended by the surgeons In many cases, however, the wooden limb, which has now been so far improved that it is actually lighter than the metal limb, is regarded both by the pensioner and the surgeon as more suitable, especially in amputations below the knee

A Case of Sexual Aberration

Colonel WEDGWOOD asked the Home Secretary whether his attention had been called to a sentence of six months' imprisonment with hard labour passed by the North London police-court magistrate on a labourer, Wright, for cutting off a tress of a girl's hair, whether he was aware that this offence was a well-known sexual aberration, and would he recommend that the sentence be remitted —Sir W JOYNSON-HICKS replied The answer to the first two parts of this question is in the affirmative The answer to the third part is in the negative

Blind Persons in England and Wales

Mr SHORT asked the Minister of Health the total number of blind persons in England and Wales on Dec 31st, 1926 —Mr CHAMBERLAIN replied The last return of blind persons registered in England and Wales was made on March 31st, 1925, and showed a total of 42,140 A further return will be asked for on March 31st next

Education of Blind Children

Mr ROBERT MORRISON asked the President of the Board of Education to give the present estimated number of blind or partially blind children who might benefit by admission to special schools, how many of these children were at present in special schools, how many in public elementary schools, how many in residential institutions, and how many were not attending any school —Lord EUSTACE PERCY replied The following are the particulars asked for —

	Blind	*Partially Blind*
Total number of blind and partially blind children ascertained by local education authorities in 1925	2000	4692
Number attending special schools	1642	2258
Number attending public elementary schools	63*	2069
Number in other institutions	33	26
Number not attending any school	262*	339

* The fact that these children are not attending special schools is due in the main to the unwillingness of the parents to have their children sent to residential schools

Mr SHORT asked the President of the Board of Education what was the number of sightless children of elementary school age on Dec 31st, 1926 —Lord EUSTACE PERCY replied The number of totally blind children between the ages of 5 and 16 ascertained by the local authorities during the year ended Dec 31st, 1925, the last year for which complete returns are available, was 2000

Local Authorities and the Blind

Mr SHORT asked the Minister of Health to state what was the number of local authorities who had availed themselves of the provisions of The Blind Persons Act, 1920, and provided schemes for the welfare of the blind and the number of persons involved —Mr CHAMBERLAIN replied There are 145 local authorities in England and Wales under the Blind Persons Act, 1920, and all of them have made, and put into operation, schemes for promoting the welfare of the blind These schemes cover all the registered blind persons in the country

Welfare Schemes for the Blind

Mr SHORT asked the Minister of Health the total expenditure upon welfare schemes for the blind during 1926 —Mr CHAMBERLAIN replied Figures are not available for the calendar year 1926 In the financial year ended March 31st, 1926, Government grants in aid of the welfare of the blind amounted to £103,994 The expenditure of local authorities was approximately £136,000 The income from voluntary sources of the voluntary agencies for the blind which are assisted by Government grant was £120,403

Government and Lunacy Law Reform

Mr SEXTON asked the Minister of Health if any action was being taken to incorporate the report of the Royal Commission on Lunacy and Mental Disorder in an Act of Parliament —Mr CHAMBERLAIN replied Steps are being taken to examine the report with a view to incorporating in a Bill such of the recommendations as the Government are able to adopt It will not, however, be practicable to prepare such a measure in time for introduction in the present Session

Inspection of Dairies

Mr SITCH asked the Minister of Health the number of dairies in England and Wales and the number inspected in the 12 months ending Dec 31st, 1926, by the two milk inspectors —Mr CHAMBERLAIN replied Information is not available as to the number of dairy farms in England and Wales, but it is estimated to be over 200,000 The number of farms inspected in 1926 by the two milk inspectors of my department was 220, these being farms for which a licence to sell Certified or Grade A (Tuberculin Tested) milk was held or applied for The responsibility for the supervision of other farms rests with local authorities

Motor Drivers and Medical Unfitness

Mr DAY asked the Home Secretary the number of applicants for licences to drive either a taximeter cab or omnibus who had been refused the same by him during the 12 months ended to the last convenient date, and the reason why these licences had been refused —Sir W JOYNSON HICKS replied 142 applicants for licences were refused during the period March 1st, 1926, to Feb 26th, 1927 The grounds of refusal were medical unfitness 42, inquiry unsatisfactory, 100 This neglects one applicant who was refused a motor omnibus driver's licence at the time, but who has since been granted one

MONDAY, MARCH 14TH

Medical Services in the Navy

On the motion that the Speaker do leave the Chair on the House going into Committee on the Navy Estimates,

Mr BRIDGEMAN (First Lord of the Admiralty), said there was one small point which was rather an important one, although it was not a question of a great deal of money That was the Royal Naval Medical Service Recruitment for that Service had been unsatisfactory for some considerable time He need not go into the causes of it A Committee was set up to look into the conditions of the service, and to inquire into the causes of the difficulty of recruiting

Commander BELLAIRS Was that exclusive to the Navy?

Mr BRIDGEMAN said that it was for all the Services As a result certain improvements had been effected, and were notified in July last in Fleet Orders The principal improvements were that greater facilities had been given to the young doctors to specialise in various branches of their profession, which were not naturally easily available in sea service Improved allowances had been given to holders of specialist posts, and charge pay had been approved for medical officers in charge of hospital and sick quarters Also any candidate who held a house appointment at a recognised hospital was allowed to ante-date his seniority by one year, the object being to attract if they could the most efficient of the younger medical students They had also established an addition to the dental officers by increasing their establishment from 48 to 64

Sir B FALLE said that if a man fell ill in the Navy he was sent to the Fleet Surgeon who on his own responsibility alone decided whether the man was to be discharged from the

Tuberculosis Research

Mr DAY asked the Minister of Health the total amount of the sums expended during the year ending Dec 31st last in respect of tuberculosis research work —Sir G HENNESSY (Vice Chamberlain of the Household) replied The sum of £4846 was expended by the Medical Research Council during the 12 months to Dec 31st, 1926, on research work upon specific problems of tuberculosis This excludes the cost of research into fundamental problems of which the bearing upon tuberculosis cannot be calculated, and also the cost, not separately estimated, of work in this subject by members of the Council's own staff in the National Institute for Medical Research

Young Persons Killed in Coal-mines

Mr CAPE asked the Secretary for Mines what was the number of young persons under the age of 18 killed in the coal-mines of this country during the months of December, 1926, and January and February, 1927 —Colonel LANE FOX replied 20 persons under 18 years of age were killed at coal-mines in Great Britain during the months of December, 1926, and January and February, 1927

Appointments.

PEARSON, WILFRED J, D M Oxf, M R C P Lond., has been appointed *Honorary Physician to* the Children's Department, University College Hospital

Manchester Royal Infirmary SUTHERLAND, D M, M D Manch, F R C S Eng, and BAILEY, K V, M C, M D, Ch B Manch, Assistant Surgical Officers, ELLIS R, M B, Ch B Camb, Cardiological Registrar, SUSMAN, W, M D Ontar, and POLSON C, M B, Pathological Registrars DRINKWATER, S W, M B, *Ch B* Manch, and MILNER, S M, B Ch Camb, Surgical Registrars, WHITROW, Miss F, M B, Ch B Manch, and MACLEAN, Miss G, M B, Ch B Manch, Clinical Assistants, SMITH, G S, M B Ch B Manch, Assistant to the *Director of* the Clinical Laboratory, SHAFFER, RAPHAEL M B, *Ch B* Manch Assistant Medical Officer in the Massage and Electrical *Department* BROCKBANK, W, M A, B Ch Camb, Resident Medical Officer MORRIS, L, M.B, *Ch B* Manch, Assistant Resident Surgical Officer, LANGFORD, G F, M B, Ch B Manch, Resident Clinical Pathologist, SANDIFORD, B P, M B, Ch B Manch, JONES, G W, M B, *Ch B Manch*, RAY, W H, B M, B Ch. Oxf, SHEEHAN, M, M B, Ch B

I was inclined to doubt the connexion between dampness and rheumatic infection. However, these altered my views, and although I should like to see how close the relationship is found by a wide and long inquiry to be, it seems to me unwise to postpone any action in the matter for the sake of securing ampler evidence. The Cardiac Subcommittee of the British Medical Association is taking counsel of the Royal Institute of British Architects, and this ought to lead to some effective action. Sir George Oatley, F.R.I.B.A., has discussed this matter with me and has given me the benefit of his long experience, which goes to show that both in preparation of the site and in building of the house itself there are possibilities of error which vary inversely as the conscientiousness of the builder. There never was a time when it was more necessary to lay stress on housing conditions. We are building not merely new houses but new suburbs on a scale beyond anything within living memory. Let us hope that there will be a marked fall in the incidence of rheumatic heart disease among the children born and brought up in these houses, but in the meantime I think it is our duty to insist on the desirability of dryness in the choice of sites and the development of building schemes.

Other Ætiological Factors

There are three or four other ætiological factors to which I must refer, though their share in any preventive plan is by no means obvious, partly because we are not yet sure how far they really do help to cause this disease, partly because it is not easy to see how their incidence can be reduced. Yet I believe a knowledge of their existence and influence may modify helpfully, if indirectly, any plans that may be devised for the prevention of the rheumatic infection.

The first of these may be dismissed in a word or two, as it is becoming generally understood that the carditis that occasionally complicates scarlet fever is really rheumatic. It seems that scarlet fever, perhaps in its attack on the tonsils, makes a breach in the bodily defences through which the rheumatic infection can enter. Any or all of the cardinal manifestations of that infection may follow, and among these we must place first in importance cardiac inflammation. In its clinical course as well as in its microscopical characteristics this is identical with rheumatic carditis, and it calls for the same prolonged and minute care.

Poverty and Life in Towns

Another much more debatable factor is the social one. Its existence is proved beyond doubt, but what we do not yet know is exactly what social stratum it is that suffers. We do know this, that cardiac rheumatism is a relatively rare disease among the wealthier classes. I may also add in parenthesis, that when it does attack a well-to-do child it is, on the whole, less to be feared than in a child less fortunately surrounded. Whether this is wholly due to the more prolonged and skilled care given to such a child, or to better food, or to a more generous reserve of energy, it is not easy to be sure. But the results that can be achieved in such children are encouraging enough to justify a hope that when hospital accommodation allows us to provide conditions of treatment for the poorer children as adequate as the wealthier ones already enjoy, we shall see a sensible reduction in the crippling effects of this infection.

But if poverty, using that term in its widest sense, is a factor in the causation of this disease, what element of poverty is it that we must blame and correct? Is it the whole complex of influences that constitute the meaning of poverty, or is it some one particular component of that complex? We may ask the same question about another influence, that of urbanisation. Here, however, we are on even less secure ground, for we are not yet sure that the city child is more liable to rheumatic infection than the rural one. This is one of the points that I hope we may be able to test by the research of which I have already spoken. In the area under consideration we have one city of 400 000 and three or four other towns or cities of 30,000 or more set in the midst of a community that is otherwise rural. If there is anything in the surmise that urbanisation tends to increase rheumatic infection, it ought to come out in this inquiry.

But supposing we do prove conclusively that this infection falls more heavily on the industrial suburbs of our great towns, what good is it going to do? I think much benefit may be derived if this knowledge is backed by increasing evidence of the importance of dampness in houses. Already there is enough in support of this triad—dampness, poverty, and urbanisation—to justify us in believing that as the public becomes aware of its existence and converts its knowledge into action we shall see a reduction in the incidence of rheumatic infection.

Diagnosis, Treatment, and Prevention

This brings me to a mention of the last of the ætiological influences of which I shall speak—namely, heredity. It is a curious paradox that while there is more and more talk of heredity as an influence in the causation of disease, we are doing all that we can to destroy the one weapon by which we can hope to have much direct influence on the familial factor in disease. In the past 20 years we have been busy providing doctors for the school child, doctors for the tuberculous and the syphilitics, doctors for the factories and the insurance societies; but no one thinks of seeing to it that every family in the land shall have a doctor. Is it because there are ceasing to be any families? If so, there is little that we can do, and, for that matter, little need to do it; but if family life is to continue and to re-establish itself in this complex experiment that we call civilisation, one thing that must be looked to is the provision of medical services for the family as a unit. Only in this way can we hope either for reliable information, or for effective action, in dealing with the familial factor in disease.

Last of all, let me plead for the retention of the hospital physician in any plan of campaign that we may devise. We ought already to have learnt from the struggle against tuberculosis that a wide clinical experience is needed if we are to discriminate between that which is tuberculosis and that which is not. I am sure this is going to prove equally true of the rheumatic infection. My own experience is that more mistakes are made in the direction of diagnosing rheumatic infection when it is not there than in the direction of overlooking that which is there. It is very difficult to recognise the imitations and nothing except long experience will ensure its being done. That experience those of us who are doing out-patient work in the general and children's hospitals have acquired; any plan that fails to mobilise that experience will be throwing away one of our greatest assets. Moreover, it is in these hospitals that our students are most conveniently trained. The unbalanced enthusiasms that have sowed clinics of all kinds here, there, and everywhere in our great cities, are making it increasingly difficult to give medical students an all-round education. If this insane tendency also gets hold of the campaign against rheumatic heart disease and diffuses its energies into special cardiac or rheumatic clinics, divorced from the places in which students are taught, we shall quite certainly fail to suppress the disease in this generation or provide for the struggle against it in the next. We are in for a long war and we must make our plans accordingly.

Let me here summarise what has been said on the steps to be adopted for the prevention of the rheumatic infection in childhood. In the first place, every care must be taken to ensure, as far as may be, prevention of damp in houses. Not only must each house be protected by the best means available against damp from below, but also no site suspected of dampness should be used. Secondly, further research must be made into the part played by social and economic factors in the causation of the disease. Third, the influence of tonsillitis and scarlet fever in predisposing to rheumatic infection must be remembered and dealt with on its own merits in each case. Fourth, more knowledge of the bacteriological aspects of the problem is much to be desired. Finally, it is devoutly to be hoped that all branches of the medical profession may be brought together in providing for early diagnosis and adequate treatment of the disease.

A RECTIFIER FOR ULTRA-VIOLET THERAPY

THE Medical Supply Association have produced a rectifier for use in ultra-violet therapy, which makes it possible to run a mercury lamp or metallic tungsten arc from an alternating voltage supply. The instrument consists essentially of an auto-transformer, in the secondary circuit of which an electrolytic rectifier of the usual type and an iron-cored choke are connected in series with the arc and its starting-up resistance. The innovation (for which a patent has been applied for) is in the choke coil which is designed to maintain steady conditions. The transformer is fitted with tappings which are used first to permit of a step-up or step-down effect according to the voltage of the mains, and secondly to allow of the arc being struck at a low voltage and then, as soon as running conditions are obtained, the higher operating voltage is applied to the lamp circuit by a change-over switch which makes contact to another tapping. The current which can be drawn from the instrument, depends on the size of the chemical rectifier, and in the case of the first models made the maximum value is about 5 amperes, a current quite adequate for the two types of lamp mentioned above. The apparatus should prove of considerable value in cases where alternating current only is available, as it permits of the use of ordinary direct current burners, whilst the inclusion of an auto-transformer in the design ensures that a high percentage of the power drawn from the mains is expended in the lamp itself. Both mercury and tungsten arcs are found to run quite steadily and normally when operated by the rectifier.

Notes, Comments, and Abstracts.

RHEUMATIC INFECTION OF CHILDHOOD.*

By Carey F Coombs, M D, F R C P Lond,
PHYSICIAN WITH CHARGE OF OUT PATIENTS, BRISTOL GENERAL HOSPITAL

I —*Concluded from p 580*

The Mechanism of Infection

I come next to a consideration of the bacteriology of the disease As Dr Poynton and I have recently published a full review [1] of this matter, you will allow me, perhaps, to state baldly and without argument a belief in the streptococcic hypothesis of the disease To my mind the view, which we owe to the long and patient researches of Poynton and Paine, that the exciting cause of these lesions is a streptococcus probably derived from and certainly very similar to those normally present in the human alimentary tract, is valid and has no rival Even those who cannot bring themselves to accept this hypothesis put forward no alternative

The most important deduction from the streptococcal theory, so far as prevention is concerned, is the futility of expecting to destroy this disease by any attempt to eradicate its infective agent This is probably a constant inhabitant of the healthy human body, or at all events a near relation of such inhabitants, and any effort to free ourselves from its existence would be about as profitable as a campaign for the extermination of the common dandelion It is not to measures of this kind, but rather to a general overhaul of the conditions under which the virus enters and injures the body, that preventive medicine must devote its energies We have, in fact, to face in this disease one in which the bacterium itself is of relatively little importance, and can only do harm when a certain group of conditions coincides to make the resistance of the individual inadequate

Let us look first at those properties of the body itself which influence its capacity to resist the rheumatic infection First, we have to scrutinise what are called the portals of entry The body is protected from the outer world not only by its skin, but also by the epithelial membranes that line the alimentary, respiratory and genito-urinary tracts These infoldings of the body's surface carry to its inmost citadel lines of lessened resistance like subterranean passages honeycombing the foundations of a fortress, and, like such secret passages, coming at points into the closest contact with the open thoroughfares of the invaded city

One of these points of contact is to be found in the tonsil a mass of lymphoid cells, one of whose chief functions appear to be to entomb and destroy bacteria On the deep side these cells are in free and direct contact with the circulating fluids of the body On their surface they are brought into an equally direct relation, through the crypts which pierce their substance, with the bacteria that live in the mouth They serve as a go-between for these bacteria and the blood of the living organism of which they are a part Perhaps it is one of their functions to make these two, the bacteria and the blood fluids, acquainted with each other, and to teach them a kind of mutual forbearance But, unfortunately, this ideal is not always attained Often the bacteria take advantage of the tonsil, so to speak, and push their way in so boldly that in spite of a stout resistance on the part of the tonsillar tissues, they enter freely into the blood fluids by which these tissues are bathed Then ensues the train of events recognised as manifestations of the rheumatic infection

Estimates of the frequency with which that infection is ushered in by a recognisable tonsillitis vary widely Probably the proportion of one-third, to which both Poynton and Miller approximate very closely, represents the general experience At all events, we may assume that in not more than half the cases the onset of rheumatic infection is declared by an act of open hostilities in the region of the tonsils And what happens in the other half ? Do the organisms sneak through the tonsils without exciting any local resistance ? Or do they enter elsewhere ? The small intestine contains very many lymphoid masses similar to the tonsils, yet—apart from an occasional and rather doubtful relation between appendicitis and rheumatism—it is difficult to trace any evidence of strife between body and bacteria at these intestinal outposts C W Vining has suggested that a relation exists between faulty dieting in childhood and the rheumatic infection, and Miller has initiated an inquiry into the bacterial content of the alimentary excreta of the rheumatic child It is generally agreed, I believe, that dental disease does not predispose the growing child to rheumatic infection At present, however, it cannot be said that we know anything for certain about any portal of entry other than that furnished by the tonsil We are not sure whether the infection always goes in by the tonsil or whether it sometimes uses an alternative route

Tonsillectomy

This uncertainty is reflected in the division of opinion that is found in the medical journals about the advisability of removing the tonsils of the rheumatic child Those who favour this plan do so because they think that to remove the tonsil is to remove the organisms that are on their way into the body to continue the evil work already begun by their predecessors Against this it is argued that removal of the tonsil does not remove from the mouth the bacteria that are potential causes of rheumatic infection, while on the other hand, it may mean removal of tissue which has an actual defensive value and thus a lowering of the resistance to the infection Also, it is possible that there are other avenues than the tonsil by which these organisms enter Unfortunately, the appeal to clinical results is answered by conflicting voices Some say that tonsillectomy is followed by freedom from evidences of active infection, others, that on the whole there is no difference between the course of the disease in children whose tonsils have been removed, and its behaviour in those whose tonsils have been left Miller's series, though limited, yielded a suggestive result, in that he found that rheumatic infection in the child whose tonsils had been removed was more often liable to manifest itself in an uncomplicated chorea than in the children whose tonsils had not been removed

Now, chorea is the most easily excited of all the rheumatic phenomena It takes a smaller dose of infection to upset the brain than it does to inflame the heart or joints, or to call into being a subcutaneous node Chorea is more often met with as a solitary manifestation of rheumatic infection than any of the others Possibly, therefore, extended experience may prove that removal of the tonsils does actually tend to reduce the severity of the infective process At the present time the sound rule appears to be to judge each case on its merits, and to have the tonsils removed if it appears from the history, or the condition of the throat on examination, or both, that these have served or are likely to serve as a breach in the defences through which the enemy may enter

Methods of Defence

Next let us consider what defensive mechanisms are at the disposal of the infected body, and by what means they may be reinforced I do not propose to enter upon a discussion of the machinery of immunity except to remind you that most infections excite against themselves not merely the general reactions by which living tissues oppose inimical particles, but also certain specific reactions which issue in the formation by the body of biochemical antidotes exactly suited to neutralise the particular poison of the moment It is this principle that is the basis of all treatment by vaccines and sera, and it is natural that we should look to such methods for help in the fight against rheumatic infection Up till now, moreover, we have had little encouragement from this quarter and, on the whole, it is not likely that we shall get much So far as there has been investigation of the immune bodies formed in reply to streptococcal infection of the heart, it has shown a remarkable variability from one individual to another This does not seem to warrant any great hope that it may be possible to add to the bodily economy from without, some standard protein antidote by which its recipient may be better defended against the streptococci of rheumatic infection It is rather from a consideration of those conditions without the body which predispose it to this infection that we shall derive the basis for a policy of prevention

Damp

First among these conditions I am going to put dampness There is a time-honoured tradition that wet feet cause rheumatic fever In its favour many isolated experiences can be quoted, but it is as impossible to prove from these a causal connexion between the two as it would be to prove that tuberculous meningitis is provoked by blows on the head, or that Mephibosheth was paralysed in both his feet because his nurse dropped him And it is difficult to counter in any effective way the fact that the Army in Flanders, during the recent war, was remarkably free from the usual evidences of rheumatic infection

Among the small group of cases analysed by Askins and Morrison, there was an appreciable number in which the parents ascribed the onset of the disease to some accidental exposure of the child to wet But more numerous and, in the light of the experience of others more significant, were the cases in which the rheumatic infection attacked a child living in a house proved by careful inspection to be damp or, at all events, built on soil within a short distance of one of Bristol's waterways Until I saw these reports

---

[1] Brit Med Jour, July 3rd, 1926

I was inclined to doubt the connexion between dampness and rheumatic infection. However these altered my views, and although I should like to see how close the relationship is found by a wide and long inquiry to be, it seems to me unwise to postpone any action in the matter for the sake of securing ampler evidence. The Cardiac Subcommittee of the British Medical Association is taking counsel of the Royal Institute of British Architects, and this ought to lead to some effective action. Sir George Oatley, F.R.I.B.A., has discussed this matter with me and has given me the benefit of his long experience, which goes to show that both in preparation of the site and in building of the house itself there are possibilities of error which vary inversely as the conscientiousness of the builder. There never was a time when it was more necessary to lay stress on housing conditions. We are building, not merely new houses, but new suburbs on a scale beyond anything within living memory. Let us hope that there will be a marked fall in the incidence of rheumatic heart disease among the children born and brought up in these houses; but in the meantime, I think it is our duty to insist on the desirability of dryness in the choice of sites and the development of building schemes.

Other Ætiological Factors

There are three or four other ætiological factors to which I must refer, though their share in any preventive plan is by no means obvious; partly because we are not yet sure how far they really do help to cause this disease, partly because it is not easy to see how their incidence can be reduced. Yet I believe a knowledge of their existence and influence may modify helpfully, if indirectly, any plans that may be devised for the prevention of the rheumatic infection.

The first of these may be dismissed in a word or two, as *it is* becoming generally understood that the carditis that occasionally complicates scarlet fever is really rheumatic. It seems that scarlet fever, perhaps in its attack on the tonsils, makes a breach in the bodily defences through which the rheumatic infection can enter. Any or all of the cardinal manifestations of that infection may follow, and among these we must place first in importance cardiac inflammation. In its clinical course as well as in its microscopical characteristics this is identical with rheumatic carditis, and it calls for the same prolonged and minute care.

Poverty and Life in Towns

Another much more debatable factor is the social one. Its existence is proved beyond doubt, but what we do not yet know is exactly what social stratum it is that suffers. We do know this, that cardiac rheumatism is a relatively rare disease among the wealthier classes. I may also add in parenthesis, that when it does attack a well-to-do child it is, on the whole, less to be feared than in a child less fortunately surrounded. Whether this is wholly due to the more prolonged and skilled care given to such a child, or to better food, or to a more generous reserve of energy, it is not easy to be sure. But the results that can be achieved in such children are encouraging enough to justify a hope that when hospital accommodation allows us to provide conditions of treatment for the poorer children as adequate as the wealthier ones already enjoy, we shall see a sensible reduction in the crippling effects of this infection.

But if poverty, using that term in its widest sense, is a factor in the causation of this disease, what element of poverty is it that we must blame and correct? Is it the whole complex of influences that constitute the meaning of poverty, or is it some one particular component of that complex? We may ask the same question about another influence, that of urbanisation. Here, however, we are on even less secure ground, for we are not yet sure that the city child is more liable to rheumatic infection than the rural one. This is one of the points that I hope we may be able to test by the research of which I have already spoken. In the area under consideration we have one city of 400,000, and three or four other towns or cities of 50,000 or more, set in the midst of a community that is otherwise rural. If there is anything in the surmise that urbanisation tends to increase rheumatic infection, it ought to come out in this inquiry.

But supposing we do prove conclusively that this infection falls more heavily on the industrial suburbs of our great towns, what good is it going to do? I think much benefit may be derived if this knowledge is backed by increasing evidence of the importance of dampness in houses. Already there is enough in support of this triad—dampness, poverty, and urbanisation—to justify us in believing that as the public becomes aware of its existence and converts its knowledge into action, we shall see a reduction in the incidence of rheumatic infection.

Diagnosis, Treatment, and Prevention

This brings me to a mention of the last of the ætiological influences of which I shall speak—namely, heredity. It is a curious paradox that while there is more and more talk of heredity as an influence in the causation of disease, we are doing all that we can to destroy the one weapon by which we can hope to have much direct influence on the familial factor in disease. In the past 20 years we have been busy providing doctors for the school child, doctors for the tuberculous and the syphilitics, doctors for the factories and the insurance societies, but no one thinks of seeing to it that every family in the land shall have a doctor. Is it because there are ceasing to be any families? If so, there is little that we can do, and, for that matter, little need to do it; but if family life is to continue and to re-establish itself in this complex experiment that we call civilisation, one thing that must be looked to is the provision of medical services for the family as a unit. Only in this way can we hope either for reliable information, or for effective action, in dealing with the familial factor in disease.

Last of all, let me plead for the retention of the hospital physician in any plan of campaign that we may devise. We ought already to have learnt from the struggle against tuberculosis that a wide clinical experience is needed if we are to discriminate between that which is tuberculosis and that which is not. I am sure this is going to prove equally true of the rheumatic infection. My own experience is that more mistakes are made in the direction of diagnosing rheumatic infection when it is not there than in the direction of overlooking that which is there. It is very difficult to recognise the imitations and nothing except long experience will ensure its being done. That experience those of us who are doing out-patient work in the general and children's hospitals have acquired; any plan that fails to mobilise that experience will be throwing away one of our greatest assets. Moreover, it is in these hospitals that our students are most conveniently trained. The unbalanced enthusiasms that have sowed clinics of all kinds here, there, and everywhere in our great cities, are making it increasingly difficult to give medical students an all-round education. If this insane tendency also gets hold of the campaign against rheumatic heart disease and diffuses its energies into special cardiac or rheumatic clinics, divorced from the places in which students are taught, we shall quite certainly fail to suppress the disease in this generation or provide for the struggle against it in the next. We are in for a long war and we must make our plans accordingly.

Let me here summarise what has been said on the steps to be adopted for the prevention of the rheumatic infection in childhood. In the first place, every care must be taken to ensure, as far as may be, prevention of damp in houses. Not only must each house be protected by the best means available against damp from below, but also no site suspected of dampness should be used. Secondly, further research must be made into the part played by social and economic factors in the causation of the disease. Third, the influence of tonsillitis and scarlet fever in predisposing to rheumatic infection must be remembered and dealt with on its own merits in each case. Fourth, more knowledge of the bacteriological aspects of the problem is much to be desired. Finally, it is devoutly to be hoped that all branches of the medical profession may be brought together in providing for early diagnosis and adequate treatment of the disease.

A RECTIFIER FOR ULTRA-VIOLET THERAPY

THE Medical Supply Association have produced a rectifier for use in ultra-violet therapy, which makes it possible to run a mercury lamp or metallic tungsten arc from an alternating voltage supply. The instrument consists essentially of an auto-transformer, in the secondary circuit of which an electrolytic rectifier of the usual type and an iron-cored choke are connected in series with the arc and its starting-up resistance. The innovation (for which a patent has been applied for) is in the choke coil which is designed to maintain steady conditions. The transformer is fitted with tappings which are used first to permit of a step-up or step down effect, according to the voltage of the mains, and secondly to allow of the arc being struck at a low voltage and then, as soon as running conditions are obtained, the higher operating voltage is applied to the lamp circuit by a change over switch which makes contact to another tapping. The current, which can be drawn from the instrument, depends on the size of the chemical rectifier, and, in the case of the first models made, the maximum value is about 5 ampères, a current quite adequate for the two types of lamp mentioned above. The apparatus should prove of considerable value in cases where alternating current only is available, as it permits of the use of ordinary direct current burners, whilst the inclusion of an auto-transformer in the design ensures that a high percentage of the power drawn from the mains is expended in the lamp itself. Both mercury and tungsten arcs are found to run quite steadily and normally when operated by the rectifier.

NEW PREPARATIONS

Ephedrine —We have received from British Drug Houses Ltd , 16-30, Graham-street, City-road, E C , samples of the tablets for oral administration and the ampoules for hypodermic use of ephedrine hydrochloride, a drug which has been found really valuable in the treatment of asthma, and prophylactically for low blood pressure in *pneumonia* The firm have been making this alkaloid in their laboratories for some months past and now are manufacturing it upon a commercial scale from the Chinese plant Ma Huang (Ephedra vulgaris) imported by them

Metaphen (Abbott) is a powerful mercurial germicide for which it is claimed that it has 500 times the strength of phenol , the chemical name is di-acetoxymercuri-4-nitro-2-cresol It is a new organic mercury compound, and experience has shown that supplied in the form of a 1 500 (or 0 2 per cent aqueous solution) it may be kept for a long time in tightly stoppered bottles without any loss of germicidal potency and unaffected by the light or temperature of an ordinary room It is odourless, almost tasteless, does not stain either the skin or garments, and, further, when used as a disinfectant, does not tarnish instruments even when they are immersed in a 1 1000 solution of the compound for a week As a skin disinfectant in dilutions of 1 5000 sterilisation can be obtained The sample bottle submitted to us was an alkalinised 1 500 solution so that the usual 1 5000 is easily made by the addition of 1 part of the preparation to 9 parts of water The bacteria employed in testing the preparation were the *Staphylococcus aureus*, gonococus, and *Bacillus typhosus*, and directions for use of weak solutions for urethral injections are sent with the preparation Other main indications for therapeutic employment are skin affections, pyogenic or parasitic, rhinitis and coryza Metaphen is supplied by E H Spicer and Co , Ltd , 72, Wigmore-street, W 1

Trixyl, as prepared by Trixyl Antiseptics Ltd , Otterbourne, near Winchester, is an antiseptic preparation designed for external and internal use and for inhalation It is stated to be a compound derived from such vegetable essences and essential oils as eucalyptol, guaiacol, menthol, thymol, and terpinol, and the inventors lay stress on its use as an inhalation in irritative conditions of the air passages An ingenious little inhaler is supplied for use with the drug, so made that the bulbous end can be used for nasal inhalations and the narrow end for buccal use

BRAILLE "WIRELESS" PROGRAMMES FOR THE BLIND AN APPEAL.

Captain Sir Beachcroft Towse, V C, K C V O, C B E, has recently broadcasted an appeal for funds for the production, by the National Institute for the Blind (Headquarters 224, Great Portland-street, London, W 1), of an adequate wireless programme in Braille embossed type—an excellent and much-needed innovation

This is an essential service for the blind, among whom are many wireless enthusiasts, these becoming participators in the life of the world At present, however, the blind are absolutely dependent on sighted friends for their knowledge of the daily programmes Much interest has been shown in the scheme by the British Broadcasting Corporation, and the *Radio Times* has already made arrangements for supplying the Institute with the necessary details of forthcoming programmes in advance of publication, and, of course, without copyright fee

As soon as £700 is raised, a weekly programme will be produced to be sold to the blind at the nominal figure of 6*s* 6*d* per annum, post free The capital sum is needed for the purchase of a new embossing machine, as the present plant at the Institute—the largest publishers for the blind in the world—is constantly at work producing Braille periodicals and books in their thousands The blind will produce their programmes themselves, the procedure being as follows As soon as the " copy " for the programme is ready, it will be handed to a sighted reader who will dictate it to a blind stereotyper, who will transliterate each word into Braille, when it is embossed on a metal plate When a plate is completed, a proof copy will be read for press correction by a blind proof-reader, when the plate will be inserted in the embossing machine, as many copies as are required being supplied on specially prepared paper The sheets are then gathered together, collated by the blind, and bound into programmes ready for delivery to all parts of the world

An appeal is now issued by Mr J De La Mare Rowley, General Editor, National Institute for the Blind, and is directed to listeners throughout the country with the hope that they will assist as generously as possible All donations should be addressed to the Secretary-General (Braille Wireless Programmes Fund), National Institute for the Blind, 224–8, Great Portland-street, London, W 1

THE FOOD VALUE OF COCOA PROTEINS

The value of cocoa and chocolate as sources of protein in the diet would appear from the work of H H Mitchell, J R Beadles, and M H Keith (*Jour Biol Chem* , 1926, 71,15-31) to be small According to these workers, cocoa, with an average crude protein content of 21 5 per cent , yields 8 2 per cent of digestive crude protein and only 3 per cent of net protein available for replenishing and adding to the body proteins Chocolate, which contains less protein than cocoa, must be even less valuable in this respect Those who use cocoa and chocolate as adjuncts to a diet which is normally sufficient or who find chocolate a useful stop-gap when stranded in districts where reasonable meals seem to be unobtainable—and there are still some such districts—will not be much disturbed at these findings. They are, however, of importance to those for whom cocoa, made with watered milk, bread, and margarine form the staple diet

PERSISTENT BOILS.

To the Editor of The Lancet

Sir,—Replying to W L C 's inquiry (March 12th, p 582) on the treatment of persistent boils, the best result will, in my opinion, be obtained by the use of " Stannoxyl," 3 to 4 tablets daily, combined with the hypodermic injection of 10 c cm sterilised milk once a week From two to three injections are required

I am, Sir, yours faithfully,
James Hasson, M.D

Cleveland square, W , March 11th, 1927

To the Editor of The Lancet

Sir,—I would suggest to W L C that he tries the following method which I have found successful in a good many similar cases Apply with a camel's hair brush to the whole area of skin affected and a wide area round it either tinc iodi or a 1-2000 or 1-3000 solution in rectified spirit biniodide of mercury every three or four days If the area is a large one it may be wise to treat it with biniodide in sections, having in view the possibility of absorption. The method is reasonable in view of the fact that boils result from infection of hair follicles by staphylococci

I am, Sir, yours faithfully,
Bruce C Kelly, M B , C M Edin , M R C S Eng

Buckland Newton, Dorchester, March 13th, 1927

THE SUPPLY OF BLOOD DONORS

To the Editor of The Lancet

Sir,—May I appeal through your columns for volunteers to join the Blood Transfusion Service which is organised by the British Red Cross Society with the assistance of the British Hospitals Association and the Rover Scouts, and is now under the management of a Committee representative of these three bodies ? During the past five years nearly 1400 volunteers, of whom a large majority were Rovers, have given their blood to hospitals, nursing homes, and urgent private cases The total number of volunteers on the list is about 350, but during 1926, 737 calls for help were made and answered, and these are increasing so rapidly —122 already this year—we shall soon be unable to meet the demands

The operation is nearly painless and quite harmless The donor is quite able to return to work after half an hour's rest without fear of after-effects The Service is entirely voluntary, but fares, time lost from work, and all other expenses are refunded by the Committee Most men between the ages of 18 and 50 and many women are competent to render the service, only eight volunteers having so far been rejected The privilege or saving a human life is given to but few, but here is not only an opportunity but a practical certainty at the cost of a few hours' time and slight personal inconvenience

May we also make a very strong appeal to employers to permit volunteers in their service to act in emergency cases during business hours ? The time lost is not great, the expense is made good, and the donor is not in the least incapacitated We ask this because there are less than 50 members at present available during the daytime, and most of these have already been used once this year, and we are told that it is not easy to get leave from employers

The Society will be pleased to send a speaker to explain the nature of the Service to organisations interested Individual inquirers may obtain particulars at any time from the Honorary Secretary, 210, Peckham Rye, S E 22 (Telephone (night and day) New Cross 1606)

We are, Sir, yours faithfully,
Arthur Stanley,
British Red Cross Society
Knutsford,
British Hospitals Association
C Lisle Watson,
Rover Scouts

19, Berkeley street W 1,
March 10th, 1927

Lumleian Lectures

ON THE

MUSCULAR MECHANISM OF RESPIRATION AND ITS DISORDERS.

The First Lumleian Lecture delivered before the Royal College of Physicians of London on March 22nd

BY SIR CHARLTON BRISCOE, BART.,
M.D., F.R.C.P.LOND.,
PHYSICIAN TO KING'S COLLEGE HOSPITAL AND TO
ST JOHN AND ST ELIZABETH HOSPITAL

LECTURE I.

INTRODUCTION

THE subject of these lectures is derived from certain observations made in the course of a research lasting more than 20 years. In 1903 when I was in Göttingen Prof. Aschoff suggested a research on the mechanism of the peritoneum in resisting infection. I well remember his answer when I objected that the work suggested was very difficult, he replied, "Yes, if it were not so it would have been done before." I should like to express my gratitude to him for stimulating the spirit of research work, which he then aroused. When this was completed I proceeded on a similar investigation in respect of the lungs in a private laboratory at King's College, the results of which were published in the *Journal of Pathology and Bacteriology* (1907).[1] This investigation showed the paramount importance of cells lining the alveoli the "staube-zellen or herzfehlerzellen" which are strongly phagocytic to inorganic and organic material. It also showed that the activity of these cells was greatly enhanced by the presence of serum. My work showed the importance of stasis allowing plasma or serum to escape from the blood-vessels into the alveoli and the importance of approximating the alveolar cells to the object to be destroyed. It was a natural step from this to investigate the mechanism by which expansion of the lungs was diminished, a process which should achieve both the objects desired.

For some three years or more I performed experiments to determine differences of action of the two halves of the diaphragm; these experiments were carried out by a modification of Head's[2] method of utilising the xiphisternal attachment of the diaphragm in the rabbit, divided into right and left halves. Many experiments were made by injections into the lung pleura, pericardium by irritation of the peritoneum or the abdominal viscera, by traction on mesentery in the endeavour to produce an alteration in the contraction of one diaphragmatic slip. These observations were, for the most part entirely negative positive results showing a reduction of 10–12 per cent of movement were obtained on the side to which heat or cold was applied, and a similar reduction when the animal was laid upon one side.

About this time, 1909 Pasteur[3] published several papers and read the Bradshaw lecture to this College on the subject of massive collapse of the lung. From the point of view of pulmonary mechanism this was a most important contribution. It provided an identification of one of the unknowns in an equation and it appeared to me that a considerable advance would accrue if it was possible to discover the factors upon which this collapse of a definite part of the lung depended. An accidental observation led to a routine examination of the muscles which act upon the thorax, both in health and disease and subsequently to an examination of respiratory movements of different parts of the chest and abdomen, which have been recorded on a kymograph.

I shall deal in these lectures with some of the results of this investigation the mechanism of respiratory movement and of pain and dyspnoea arising in respiratory muscles. The first step must treat of respiratory movements in general.

CONCERNING NORMAL RESPIRATION.

The generally accepted theory of the mechanism of respiration postulates a respiratory centre or centres lying in the lower part of the pons and medulla from which fibres pass to the phrenic nuclei lying in the middle region of the cervical spinal cord. From this spinal centre originate the phrenic nerves, whose principal function is to conduct impulses to the diaphragm causing it to contract. The thoracic respiratory muscles must also be activated by connexions with these centres. The depth of each respiration so produced is regulated through the vagus by means of impulses arising, either from the volume of the lung, according to the Hering-Breuer[4] reflex, so fully investigated by Henry Head,[2] or by impulses arising from the passage of air over the bronchial mucous membrane, as suggested by Lumsden.[5] These impulses acting on the higher respiratory centre control the respective phases. The higher centre is governed by the pressure of CO_2 in, and the reaction of, the blood. It is, however, generally recognised that either the higher or lower centre can be affected by other means. It is obvious that a certain amount of conscious control of respiratory movement either of the chest or of the diaphragm is present in most individuals. It is equally obvious that pain and certain subconscious processes, so frequently illustrated in novels have an influence upon the type of respiration.

In general, the body does not work its various organs to the full. I think that that is a deduction made from Sir John Rose Bradford's work on the kidney,[6] which showed that it was necessary to remove at least three-quarters of the kidney before polyuria developed. Keith[7] has stated that the respiratory mechanism under ordinary circumstances works only at 5 per cent or 10 per cent of its capacity.

It is therefore clear that in the general muscular mechanism of respiration a very considerable degree of selection is possible as to which muscles diaphragm or thoracic shall contract. They are not all wanted *all* the time, but *all* are wanted some time or other, and we should expect that apart from conscious control the body will have some means of calling on now one muscle, now another, to do extra work—or a different type of work—to accommodate the act to the variable circumstances of life. I shall show later that such a mechanism exists, and that it is of clinical import.

Though it is a commonplace of the text-books that respiration in man is either diaphragmatic or thoracic, yet none mention the features characteristic of the two types, or attach importance to the subject, and there is a general tendency among clinicians to consider inspiration and that forced and voluntary, alone, except in a few pathological conditions in which expiration is obviously obstructed.

RESPIRATION DIAPHRAGMATIC OR THORACIC

I know of no work which attempts to explain the interdependence or differentiation of these types of breathing abdominal and thoracic. My task is, therefore, rendered considerably easier in that I have not to refer to the very large body of literature which exists on the subject of respiratory movements, dating from the time of Hippocrates down to the present day.

In the Arris and Gale Lecture[8] (1919) I drew attention to the characteristic features of the two types of respiration—viz., the diaphragmatic in which respiration is carried out practically entirely by the diaphragm (demonstrated externally by protrusion of the abdomen) and the thoracic, which is characterised by expansion of the bony thorax. Although the majority of individuals represent a combination of these two mechanisms in varying proportions this distinction of type must form the basis of any study of the mechanism of respiration. Such a study will involve an investigation of the movements of different parts of the chest epigastrium &c., and of the muscles which produce such movements.

I propose in this lecture to try to elucidate the various factors which influence the general type of quiet respiration seen in different individuals (as determined by tracings of movements and action of muscles) I should like to emphasise the fact that this part of the investigation has been made on normal individuals at rest, and as far as possible under circumstances in which the attention has not been directed to the question of breathing

Method of Investigation —The first difficulty that has to be contended with is the elimination of the effects of those muscles which are concerned with maintaining the balance of the body, for when standing the body sways continuously, requiring action by the muscles of balance, some of which are attached to the thorax, and exert influences on respiratory movements * With this object, and to make the results as practical as possible, I have adopted a standard posture for investigations. The subject is placed on a couch, the back of which is inclined at an angle of 45 degrees, and a pillow is placed beneath the shoulders, the head being suitably supported This enables a comparison of results obtained on normal people with those obtained on the sick, for the posture described is a comfortable one for examination of bedridden patients In this posture the muscles of the back, which is in contact with the couch, cannot be examined. Similarly, tracings are confined to movements of the anterior and lateral aspects of the chest and abdomen

Natural Variability.

I can state at once that in my investigations by chest tracings I have never met with two individuals who breathe in precisely the same manner, nor is it possible on successive days to secure identical tracings of the same individual.* This is not due to faults of technique. It is practically impossible to adjust an individual in exactly the same position on two successive days, or to guarantee an identical condition of his abdominal contents. The second reason for constantly finding differences arises from the point mentioned above—namely, that conscious and subconscious processes exert an influence on the manner of respiration

Differentiation between the Two Forms of Breathing

With this outline and criticism of the general methods I can proceed to the main part of the work, the differentiation and relationship of thoracic and diaphragmatic breathing and the muscles acting in either form †

IMPORTANCE OF EXPIRATION.

The general mechanism of inspiration is much more complicated than that of expiration There is considerable physiological evidence for considering that expiration, the excretory act of the lung, is of more importance than inspiration, for carbon dioxide plays a more important rôle in the immediate regulation of respiration than does oxygen I shall, therefore, proceed to discuss expiration, and to consider inspiration as a means of preparing for the former act

The Quadruped.—If we examine the mechanism of expiration in the quadruped it is clearly largely a passive act The relationship of the abdominal viscera to the diaphragm is such that when the diaphragm, after contraction, relaxes, it must be carried into the position from which the next inspiration will follow, by the weight of the liver and other abdominal organs In addition the effect of the elastic contraction of the lungs must be considered, and this, I may remind you, is of extreme importance in all questions of respiration.

In an experimental animal breathing deeply under an anæsthetic the chest moves but little, and expiration depends on the elastic recoil of the lungs, which may be assisted by the weight of the abdominal viscera The abdominal muscles do not contract The effects of obstructing expiration are instructive If the animal be allowed to inspire freely, but is made to expire against resistance, and such resistance is gradually increased, it will be found that with each inspiration the diaphragm attains a lower level and thus fills the lungs with more air It is only (in the case of a cat) when 13 or more centimetres of water are the obstructing force that any sign of increased chest movement and contraction of the abdominal muscles is observed Short of this point the expiratory force seems to lie in no muscle but in the lungs alone, and if the resistance is slightly diminished, so that some air can be expired in spite of the resistance, the chest walls will not come into action unless, and until, asphyxia is beginning to develop—that is to say, with 7 or 8 cm of water pressure obstruction, expiration is carried out by the lungs alone In the cat in a vertical position with the abdomen widely opened the elastic recoil of the lungs is sufficient to elevate the diaphragm, liver, and stomach, with the added load of 25 g There is no reason to think that the human lungs are less efficient

In quadrupeds, therefore, quiet expiration is carried out by the elastic recoil of the lung associated with a passive falling back of the diaphragm Thoracic expiration, such as it is, and confined to the lower part of the chest, may be either due to elastic recoil of the ribs or assisted by muscular action

In Man —When we apply these factors of the mechanism of expiration to the upright posture of man we find the conditions different The elasticity of the lungs remains, but consequent upward movement of the relaxing diaphragm is hindered by the action of gravity on the abdominal contents We are met with a new condition in the development o greater respiratory movement in the thorax, notably in the upper ribs, which are not now used to support the weight of the body Gravity will, however, operate to depress the thorax elevated in inspiration.

Thus we see that orthograde man has converted the help of gravity on the diaphragm in expiration into a loss, but has gained by taking his weight off the upper limb, and so allowing the thorax to expand more easily.

The Action of the Abdominal Muscles

The action of the abdominal muscles in man is important in this connexion. It is tempting to think that the abdominal muscles by their contraction on the abdominal viscera are reciprocal antagonists to the diaphragm, and will push the diaphragm upwards I believe that this is not their function though the elastic recoil of the abdominal wall may have such an effect

We find that there are a number of people who, examined in the standard posture I have described, protrude the epigastrium by means of the diaphragm during inspiration, but develop no contraction in their abdominal muscles which can be detected either in inspiration or expiration. In another class abdominal muscular contraction can be detected during expiration; if constriction be applied to the lower part of the thorax in these individuals the abdominal muscles become quiescent, although the inspiratory propulsion of the abdomen is increased And again, if an individual is laid supine there may, or may not, be expiratory contraction in the abdominal muscles, but in any case this is produced or increased when the foot of the couch is elevated This elevation of the foot of the couch must increase the tendency of the abdominal contents, by the action of gravity, to move towards the head, and thus press the diaphragm up and assist expiration, and in this case the abdominal muscular contraction would be redundant At the same time this position does tend to cause the thorax to proceed in the cephalic direction, and in order to produce the next inspiration it is requisite that the thorax be restored to its original position—that is, towards the hinder extremity. The abdominal muscles in this position must act as depressors of the thorax Further, in the case of a boy with congenital absence of all abdominal muscles,[10] respiration was chiefly by the diaphragm and not, as anticipated, by the thorax[*] This boy could play full back at Association football

---

* The asterisks throughout refer to points demonstrated by means of lantern slides

† It is worth drawing attention to the fact that many investigations * have been made on the diaphragm to show that it is not of the same constitution as an ordinary voluntary muscle These have failed to demonstrate any difference of structure between the muscle-fibres of the diaphragm and those of other [illegible] muscles, and I shall show they are similar in resp[illegible]

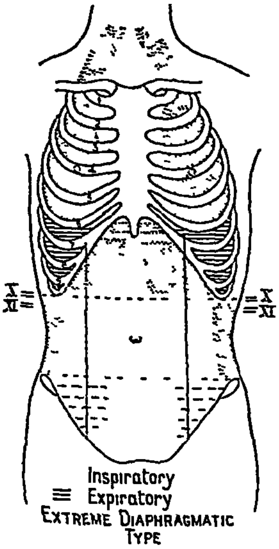
There is thus good reason to believe that the abdominal muscles connected to the thorax assist in the expiratory act of the thoracic mechanism, and not in that of the diaphragm, and we must accordingly assume that in the orthograde who inspires mainly with his diaphragm the important function in expiration is the elastic recoil of the lung.

Inspiration Preparatory to Expiration

(*a*) *Diaphragmatic*—In quadrupeds inspiratory enlargement of the cavity of the thorax is mainly in the long axis of the body In orthogrades there is the additional capacity to enlarge in the transverse and anteroposterior diameters In animals there is but little thoracic expansion, the mechanical advantage in expiration lies in a preceding inspiratory increase of the long axis of the thorax, for it is in this axis that the main bronchus to the lower lobe is to be found, and it is around this structure that the great mass of elastic tissue of bronchi and vessels is situated In man the cavity of the thorax can be increased in this direction by two means, by the depression of the diaphragm, or by an elevation of the thorax, the diaphragm remaining taut, and can be further increased if the lower borders of the bony thorax, from which the taut diaphragm takes origin, are depressed In man, the muscles which can be palpated and are found to be concerned in this act of enlargement are, at the upper part of the thorax, the scalenes and, at the lower part, the external oblique controlling the tenth, eleventh, and twelfth ribs, that part of the transversalis abdominis controlling the seventh, eighth and ninth, and that part of the triangularis sterni controlling the sixth rib (Figs 1 and 2) By these muscles the whole chest is elevated and the three lower ribs tend to be moved towards the pelvis The sixth, seventh, eighth and ninth are drawn towards the middle line and depressed, or prevented from rising during inspiration Elevation of the thorax by the scalenes alone causes an increase in the anteroposterior and lateral diameters This is seen in cases of paraplegia from lesions in the lower cervical and upper dorsal regions This elevation of the thorax by the scalenes has a somewhat similar effect on the upper ribs to that produced by contraction of the intercostal muscles These ribs are raised and the anteroposterior diameter especially the transverse to some extent, are increased The lower end of the sternum is rotated forwards owing to the greater length of the sixth and seventh ribs

When expiration occurs these muscles relax, the chest as a whole descends by gravity, and to restore the lower ribs to their original positions the intercostals of the lower spaces contract This muscle complex is one not infrequently met with in those whose type of breathing is not at all thoracic or intercostal They are of the type of visceroptosis or provisceroptosis It is noteworthy that in inspiration both the diaphragm and the muscles of the abdominal wall in the epigastric and lateral regions contract, leaving the umbilical and hypogastric regions unprotected by muscular effort

FIG 1



The contraction of the upper intercostal muscles is much less in the extreme diaphragmatic type of breathing than in the extreme thoracic type

FIG. 2

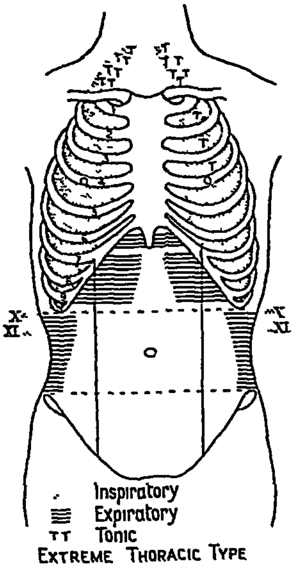


FIG. 3.

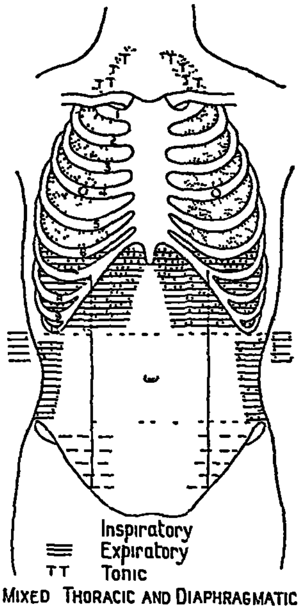


(*b*) *Thoracic*—The thorax can be expanded in its individual parts by the intercostal and interchondral muscles which elevate and evert the ribs The greatest increase is in the transverse axis In this type of breathing, when easy, the thorax as a whole is not elevated by the scalene muscles In the thoracic type as an auxiliary to inspiration the chest can be held elevated as a whole by the scalene muscles, and especially by the anterior scalene which possesses a mechanical advantage over the other scalenes as regards elevating By raising the first rib a mechanical advantage is afforded to the ribs lying caudalwards By holding the first rib elevated this mechanical advantage is further increased, the ribs being already partially raised and everted prior to the commencement of the intercostal inspiratory contraction[‡]

In expiration the intercostals relax and the ribs descend, but the elevation by the scalene action frequently remains This type is found in those who do not distend the abdomen in inspiration, but in whom the epigastrium may actually recede

The structure of the lung is such that the elastic recoil cannot be as great in the transverse as in the longitudinal axis Expiration in the thoracic type of breathing is assumed to be dependent on the force of gravity acting upon the elevated ribs causing reduction of the lateral and anteroposterior diameters, the muscles elevating the ribs relaxing These diameters can be further reduced by the constricting action of the triangularis sterni, transversalis abdominis, and lateral oblique muscles * The elastic recoil of the ribs and cartilages may also play a part It is, however, uncertain whether the recoil assists inspiration or expiration

---

[‡] Sometimes, in addition, a contraction can be felt during expiration in the scalene muscles, and if so it will be found in the anterior scalene The explanation of this latter contraction is not obvious Prof Barclay Smith has suggested that in some cases its arrangement may be such that by contracting it pulls back the first rib, and so tends to depress the thorax or it may ease the descent of the thorax The interchondrals of the upper spaces occasionally contract during expiration though usually this action is inspiratory

The purer the type of thoracic breathing the less will be the increase in the long axis and the less the expiratory action of the elastic tissue of the lung in that particular axis Expiration will be the more efficient the greater the elevation and the eversion of the ribs during the preceding inspiration

Again we find the muscles in the epigastric and lateral abdominal wall regions contracting simultaneously, but in expiration, and no contraction occurring in the umbilical and hypogastric regions In the expiratory phase, however, there is not such an increased intra-abdominal tension, the diaphragm not descending There is, therefore, not the same tendency to a yielding of the hypogastrium as occurs in the diaphragmatic type

COMBINED DIAPHRAGMATIC AND THORACIC

Thus it is seen that we have an apparent paradox in that a muscle may be now inspiratory in function, now expiratory The combinations which occur in the average individual who is a mixture of these extreme types (Fig 3) make the matter one of great complexity The contraction which helps inspiration in the pure thoracic type may have the *opposite effect* in the diaphragmatic type and help expiration—e g , the intercostal muscles of the lower spaces Further, a muscle may be both inspiratory and expiratory in action during the course of a single complete respiration A common example of this latter is found in the actions of the triangularis sterni In addition some of the powerful muscles concerned in maintaining posture are attached to and affect the movements of the whole or parts of the thoracic cage—e g., the rectus abdominis The important fact to remember is that in *any individual an alteration of attitude or position of body will alter the manner of breathing*, as a result of alteration in and the contraction of different muscles.

CONDITION OF MUSCLES NOT ACTIVELY CONTRACTING

A further very important question in connexion with the muscular side of the respiratory act is that of the condition of those muscles constituting the walls of the thoracic cavity during any period when they are not actively contracting Though in this sense they may be relaxed their condition in no way resembles that of paralysed muscles They are in a condition of postural tone, which is appreciated as a persistent resistance by the finger In the same manner the diaphragm, however small may be the contraction of the dome in the thoracic type, must maintain a continuous degree of tone, otherwise it would be drawn up into the chest during inspiration Such an *inspiratory elevation relative* to the chest wall has, I believe, never been seen by the X rays except where the phrenic nerve is paralysed

I therefore believe that those respiratory muscles which are neither actively contracting nor in flaccid relaxation are in *a condition of mild persistent contraction—postural tone* ||

As stated previously, the majority of individuals *tend* to employ a combination and alternation of these two mechanisms, the thoracic and diaphragmatic, and the conditions under which various movements occur now remain to be discussed This involves a consideration of the present-day teaching in respect of nervous impulses and muscular contraction

Physiology—The all-or-none theory is accepted for both By this is meant that if a nerve-fibre conducts an impulse at all, it will be of the maximal strength possible for the condition of the nerve at that time, and similarly, when an individual muscle-fibre is excited its response is maximal if it responds at all In order to account for the graduated action of muscle, it is assumed that except in maximal activity all the nerve-fibres of a nerve are not activated at the same time, and, therefore, all the fibres of a muscle supplied by the nerve are not brought into action at the same moment As regards the nature of nerve discharge, it has been shown by Dittler[11] in the phrenic nerve that both during inspiration and expiration action currents can be detected, and that in inspiration these are at the rate of a considerable number per second They have been variously estimated at 30 to 90 or more per second

Of muscle there are several functions which should be mentioned As regards the actual contraction of muscle, Starling [2] states, "So far, therefore, the evidence is in favour of the view that voluntary contraction and tonic contraction of all skeletal muscles are discontinuous in nature, and analogous to the tetanus which we may evoke artificially by rapid stimuli, either of muscle or of motor nerve," and again, "Both in muscle and nerve the evidence is that each contraction is a fused series of single contractions evoked by discharge down the nerve of 50 to 70 excitations per second" There is also evidence to show that summation of nervous stimuli is responsible for the slow tetanic contraction of muscle and such nervous impulses must of necessity be minimal The example quoted by Starling is that of the retractor penis For this muscle a stimulus can be found which is insufficient to produce a contraction If repeated, the first three or four may be ineffective and then contraction occurs, increasing with each succeeding stimulus until a maximum is attained The same initial increase of effect is observed when a voluntary muscle is excited continuously by recurring stimuli

The term "tone" is applied to muscle in two senses, first, in the popular sense in which tone indicates well-being Of the factors concerned in this little is known, except that when individuals are in general good health the tone of muscle is also good, and it may be assumed that such conditions as produce ill-health have a certain effect in diminishing the tone of the muscles

The second application of the term "tone" is connected with the condition of postural tone, which has been so largely elucidated by Sherrington[13] *Postural tone* implies a condition of contraction of muscle to maintain a part in a certain position against resistance, and can be sustained for long periods Action currents have not been detected hitherto in this condition It is chiefly concerned in the maintenance of certain postures such as standing and can be relaxed or resumed in accordance with the needs of the body when movements are performed or cease Sherrington gives as an example, which is readily understood, the condition of the bladder which maintains a constant pressure on its contents, although allowing a gradual addition to those contents It is, theoretically, quite probable that such a condition *exists in the respiratory muscles to prevent intercostal* spaces falling in to *maintain* thoracic elevation, and to maintain the level of the *diaphragm*

There *is also to be considered* the effect of tension of the muscle, or as it may *preferably* be called "*stretch*" This was the subject of work by *Blix*,[14] who showed that the degree of response of the muscle was considerably affected by the degree of *stretch*—i e , that stretching the muscle passively tended, within limits, to increase the strength of contraction when stimulated

This was also demonstrated by Prof Starling[15] in the Linacre Lecture as being of supreme importance in the response of the left ventricle of the heart

---

|| The condition of inspiratory recession in the epigastrium which is met with in the marked type, and which formerly was attributed to a paralysis of the diaphragm is I believe the result of the sudden relaxation at the end of inspiration of the transversalis abdominis, and the resultant equally sudden eversion of the lower ribs, carrying with them the upper abdominal viscera, which allows a sinking in of the epigastrium Under such conditions a late and slight degree of propulsion is frequently seen in the epigastrium at the end of inspiration

when the output by the aorta was hindered. He showed that a process occurred by which the ventricle, not emptying itself fully with each contraction, dilated and accommodated more blood, thus stretching the individual muscle-fibres The subsequent contractions were, within limits, increased in force until the obstruction was overcome There is an optimum degree of stretch for this reaction With greater or less degree of stretch the strength of contraction diminishes

It remains to see whether these physiological laws can be applied to, and explain some of the phenomena which have been observed clinically

Of Nerve—Muscle Preparations

The problems connected with nerve and muscle have been freely studied by physiologists, but in a manner which, though producing interesting and valuable results to the physiologist, are of little direct use to the clinician The stimulus applied to the nerve is of such a strength that it is extremely improbable that stimuli or muscle contractions of similar strength ever occur under natural conditions Both in form and degree the contraction produced by maximal stimuli is totally unlike that which occurs in the body, and in order to arrive at conclusions which might assist clinical observations, it became necessary to imitate more closely the conditions which actually occur in the body.

Clinical Observations

The clinical observations which led to this line of investigation were 1 The effect of abdominal distension, with ascites or meteorism In the supine position the respiration is mainly diaphragmatic with epigastric protrusion When distension is relieved, the respiration becomes mainly thoracic 2 The contrast between the conditions present when the individual changes from a condition of standing slack to the upright The change from standing slack to the upright posture is associated with a diminution of the epigastric propulsion, thus indicating a diminution of excursion of the diaphragm This alteration is accompanied by a change in the relationship of the sternum and front part of the chest to the spine

Applied Anatomy.

The measurement from the spine of the twelfth dorsal or third lumbar vertebra to the articulation between the gladiolus and xiphisternum§ (the anteroposterior measurement) varies in the two postures It is increased in practically every individual when changing from the slack to the upright to some extent The actual difference, though not great, is of considerable importance, it varies from nothing to 2 cm , is least marked in those people of the pronounced abdominal or thoracic types of breathing, and more marked in the average individual, a combination of these two types If an allowance of 3 in , or 7 cm is deducted for the structures external to the diaphragm, the vertebra and sternum, &c., this will leave a measurement falling between 7 25 and 14 cm for the distance between the inner surfaces of the vertebræ and the back of the sternum or seventh costal cartilage Increasing that distance by a centimetre is adding to that distance an amount equal to 14 per cent down to 7 per cent The percentage when applied to the muscular part of the diaphragm is greater than the figures given, for no allowance has been made for the central tendon which should be credited with from 2 to 5 cm

The movement of flexion and extension of the spine takes place chiefly in the lower dorsal and upper lumbar regions The tendon of the crus of the diaphragm arises from the third lumbar vertebra; muscle-fibres of the crus arise from this tendon and also largely from the tendinous arch over the front of the aorta at the level of the twelfth dorsal vertebra

It is in this mesial anteroposterior direction that the diaphragm is least curved, and is maintained in position of elevation by the right border of the pericardium, and also it is in this direction that the fibres stretching from the bony points to the central tendon are of shortest length A considerable alteration in the stretch of the muscle-fibres is thus produced in the mesial anteroposterior portion of the diaphragm when changing from slack to upright It was concluded from this observation that the effect of the change from the slack to the upright posture increased the stretch and therefore the contraction of the mesial anteroposterior portion of the diaphragm, and diminished the stretch on, and the contraction of, the remaining portion

Experimental Confirmation —This latter point—stretch in the dome of the diaphragm—is difficult to substantiate owing to the curved condition of the muscle, and it was speculative Accordingly, in collaboration with Lady Briscoe,[16] the matter was investigated experimentally by her on the cat, and it was shown that the speculation was correct A pneumothorax was made on one side and records taken from the crus, and from that part extending from the central tendon to the costal border in the midaxillary line, the dome

It was found that in the ordinary experimental position the crus began to contract before the dome * When the back of the animal was slightly overextended the contraction of the dome was diminished and retarded * When the back was flexed the contraction of the crus was diminished while that of the dome was increased and appeared earlier * In this position it was clearly seen that the dome was pushed up towards the head by the abdominal viscera

Similar results were obtained by weak electrical stimulation of the phrenic nerve

When the abdominal cavity was distended with saline, thus imitating the pathological condition arising in the presence of ascites, the animal being in the usual flat position, the dome was also pushed up and its contraction became bigger and was advanced relatively to the crus as the abdominal distension was increased * These results could clearly be attributed to the stretch reaction

Importance of Stretch Reaction —This demonstration is important as showing that the stretch reaction in the diaphragm is the same as that which occurs in a skeletal muscle An increase of stretch causes· (1) an earlier contraction , (2) a stronger contraction in the muscle It would thus appear to be a general reaction found in the heart, diaphragm, and skeletal muscles, and accordingly should also be applicable to the other muscles of respiration

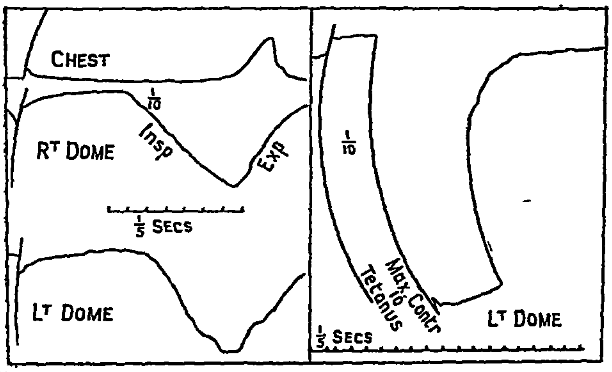
Importance of Strength of Stimulus —The position arrived at, therefore, was that a stretch reaction explained this variation in the magnitude of the contraction in the diaphragm, that the same had been shown for heart muscle, and that Blix's law showed the same for ordinary skeletal muscle Blix, however, had used maximal stimuli, and it remained to see whether the law still held with submaximal stimuli more akin to those which we believed to occur naturally Accordingly the general question of the effect of increased stretch with weak stimuli was further investigated by Lady Briscoe [17] on the following lines The gastrocnemius (rabbits and cats) and the sciatic nerve were exposed ; no other dissection was made except that the tendon of the muscle was attached to a recording lever , the muscle could thus be stretched or relaxed by simply altering the position of the foot Weak break shocks were then sent in at regular intervals ; it was found that the muscle, when put on the stretch, responded to stimuli which were ineffective when the muscle was relaxed * This distinction failed when the sciatic nerve was severed from its connexion with the cord

Objection might be made to the assumption that experimental stimuli are stronger than those which occur under ordinary circumstances in the body. To meet this objection it is necessary to produce a contraction artificially which should resemble that which occurs under ordinary circumstances in the body, as opposed to the contraction produced by maximal stimuli. The diaphragm offers an ideal muscle for such an investigation because the normal respiratory movement of one half can be employed as a pattern to the result of artificial stimuli to the cut phrenic of the opposite side A very presentable imitation of the normal movement has been obtained by Lady Briscoe [18] by the following means —

---

§ This is a convenient point of measurement, as giving similar relationships to that between the vertebral points and seventh costal cartilage one and a half inches from its junction with the sternum, this latter being the point of attachment of the diaphragm muscle anteriorly, and nearest to the middle line

FIG. 4.



Left half — Right dome is responding to a natural stimulus Left dome (paralysed, phrenic cut) responding to a graduated electrical stimulus *Natural contraction 1 1/5 second*
Right half — Left dome response to maximal tetanising current Maximal contraction attains in less than 1/5 second a shortening three times greater than a normal contraction

The only dissection required is opening the abdomen to fix hooks on the under surface of the domes, and a dissection of the phrenic nerve on one side The nerve is then tied off and cut and artificial stimuli applied in the following manner The electrodes are placed and left in position A faradic current used with a secondary coil which can be freely moved to increase and decrease the current is connected to the electrodes The coil is placed so that a very weak current is passing through the nerve, but insufficient to produce any contraction When the lever on the control side is seen to commence moving in inspiration the secondary coil is pushed up so as to increase the current The lever on the experimental side then proceeds to move, and the tracing shows a graduated contraction of the experimental half of the diaphragm This is in complete contrast to the contraction produced by a maximal single stimulus (Fig 4) This is precipitate and considerably larger than the control side When the contraction of the normal side has ceased and expiration is commencing the coil is gradually drawn down to its original position and produces a graduated relaxation So far as I know this is the first successful demonstration of an imitation of a normal contraction and emphasises the submaximal character of normal stimuli and contractions

Deduction —Several points arise from this experimental work · (1) The nerve discharge in ordinary respiration is not as great as that evoked by the usual maximal stimulus (2) The diaphragm is accordingly not forced into a maximal contraction (3) The nerve discharge is one which waxes during an ordinary inspiration and wanes during expiration (4) The influence of stretch is of paramount importance both in the selection of which muscle or part of the muscle shall contract, and in the degree of contraction, and in the time of commencement of the contraction

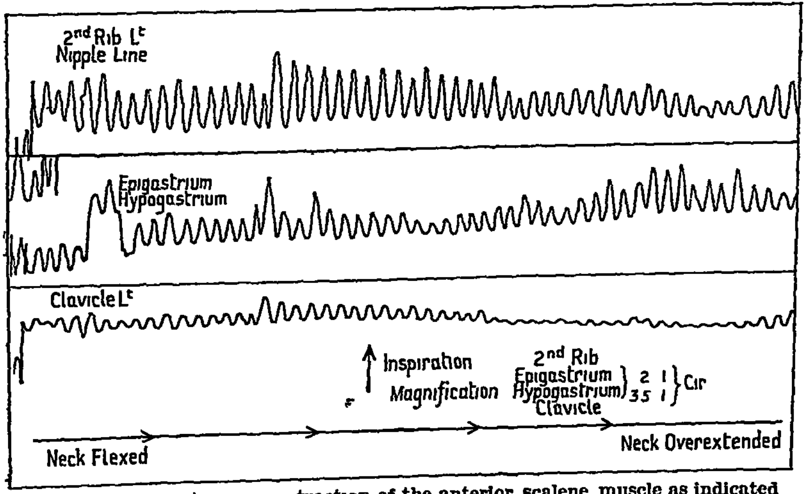
As a corrollary. when evaluating an increased movement in a tracing we must appreciate that there may be an underlying increase of stretch in the muscle or muscles

THEORY BASED ON EXPERIMENTAL RESULTS

If, then, we picture the crescendo of impulses descending the nerves which innervate the respiratory muscles of respiration, those muscles will contract first and most which are in the most suitable degree of stretch If such contraction increases the stretch of other muscles, these will in turn contract, and the shower of impulses will continue until the respiratory centre has been satisfied and an adequate amount of air has entered the lungs This will entail a certain expansion of the thoracic cavity Such an expansion may occur through the action of the domes of the diaphragm or through the muscles which expand the bony thorax Which of these two sets of muscles is *ultimately* in action will depend upon whether the domes of the diaphragm are in a greater degree of stretch than the remaining muscles of the thorax, if the dome is not in a suitable degree of stretch to pick up the stimuli these will then activate the muscles which operate on the chest wall It will thus be seen that I am according the greatest function to the diaphragm, and consider that the chest is of secondary importance This is supported by the fact that normally in practically every case the epigastric movement precedes the movement of any part of the thorax, though the relationships can be varied

Similarly for expiration, if the natural forces of lung elasticity and gravity are insufficient, or muscular action is required, those expiratory muscles operating on the thorax under stretch will contract

FIG. 5



To show the variation in contraction of the anterior scalene muscle as indicated by the clavicular movement The neck passes from flexion to over extension passively It shows (1) inverse relation of diaphragmatic and thoracic movement, (2) direct relationship of clavicular and costal movement, (3) optimum degree of clavicular and costal movements half way through the passive movement of the head *Note* —3 5 1 refers to clavicle only

FIG 6

From left to right (1) from a point half way between nipple and mid-sternal lines, (2) from mid axillary line, (3) from posterior axillary line, (4) from the top of the twelfth rib, (5) from the crus

Application of Theory to General Observations

The same law of stretch explains the following phenomena observed clinically: 1 All conditions producing extension of the spine diminish the tension in the domes of the diaphragm and so increase the tendency to thoracic expansion by widening the intercostal space Such are: (*a*) change from slack to upright by order deliberately or subconsciously in anger anxiety, &c , (*b*) supine posture or reclining when the surface on which the back rests is flat

2 All conditions increasing flexion of the spine increase the stretch in the domes and diminish the intercostal spaces and the tendency to thoracic expansion: (*a*) change from upright to slack, (*b*) reclining as in a hammock or similar arrangement. If the latter is pushed to the extreme the intercostals cease to contract at all and the spaces recede in inspiration

3 Increased intra-abdominal pressure by gas or fluid will place the domes under stretch and promote contraction and diminish thoracic expansion.

4 With the back in a constant position, extension of the head increases the stretch of the anterior scalene, elevates the thorax, and produces an increased movement of the ribs (Fig 5)

5 Lateral flexion of the spine increases the movement of the ribs on the convex side; the intercostal spaces are rendered wider and the muscles put on the stretch Conversely on the concave side the spaces are narrowed, the muscular adjustment approximated, stretch is decreased, and the action diminished

6 Elevation of the ribs by the intercostals increases the stretch on the transversalis triangularis, and lateral abdominal muscles, and renders them receptive to expiratory impulses

7 When these muscles contract in inspiration, and pull down the lower ribs, the lower intercostals are stretched and contract in expiration.

8 In the analysis of tracings of respiratory movements I find that the larger the contraction the earlier it appears to commence (Fig 6)

The construction of the diaphragm is in accord with this theory, for where the shorter length of muscle from origin to insertion is found, there is the greater mass of muscle-fibres [*] This is an optimum condition for efficiency on the basis of the stretch reaction.[†]

SUMMARY

The question of stretch then governs the order in which muscles will contract and the power they will put into that contraction The diaphragm is almost the only respiratory muscle worth considering in quiet breathing in animals and remains the most important in man though in him it has lost some mechanical efficiency through his orthograde habit Man is forced to compensate for this relative deficiency of the diaphragm by a greater use of other muscles, these other muscles acting either by active contraction or by persistent tonus of postural type If exaggerated these actions are not a normal use of muscle but an abnormal over-use, and in consequence a possible source of trouble

(*The bibliography, to which references are given in this lecture, will appear with the third lecture*)

[†] As a corollary, the varying length of muscle-fibre must lead to variations in stretch effect, the longer fibres will be the least influenced by a given stretch The longest fibres of the diaphragm are those which originate in the axillary area where also the bulk of muscle is least. I therefore think that these are the last of the diaphragm fibres to come into contraction, and the first to fail to contract Such a conception is suggestive in relation to physical signs—e g , of pleural effusion.

NEW HULL INFIRMARY—Plans have been completed for the erection of a new infirmary with 500 beds at Sutton, East Yorkshire, on a site of 50 acres, given by Mr Phillip Reckitt The cost will be about £15,000.

LIVERPOOL HEART HOSPITAL—Good progress during its first year was reported at the annual meeting There are at present only 17 beds, but the committee are anxious to open three more wards of 12 beds each.

LECTURE III.[*]

CAUSES OF THE INCREASED VENTILATION.

THE results of the examination of the arterial blood in these cases agree in general with those of other observers In spite of using venous blood for the construction of the dissociation curve and so obtaining values for the carbon dioxide pressure that may err on the high side, Campbell, Hunt. and Poulton[20] found that while some cases of mitral stenosis with dyspnœa had low arterial carbon dioxide values, others had raised values with a fall in oxygen saturation They found the carbon dioxide combining power about the lower limit of the normal, and the hydrogen-ion concentration within normal limits The patients with arterial disease and myocardial degeneration investigated by them had more pronounced pulmonary complications than those in this series and their findings in them were similar to those in the third group in this series Peters and Barr[21] considered a carbon dioxide acidosis to be the cause of cardiac dyspnœa, but base their opinion on dissociation curves constructed with venous blood Peters[38] found the alveolar carbon dioxide pressure to be low in comparison with the capacity of the venous plasma, and presumed that the hydrogen-ion concentration of the blood was raised Peters and Barr,[21] and Campbell, Hunt, and Poulton[20] found that the carbon dioxide pressure in the arterial blood is higher than that in the alveolar air in severe failure Several writers have reported on the arterial carbon dioxide content and on the capacity or combining power in heart failure, notably Harrop,[18] Barach and Woodwell,[19] and Meakins and Davies[2] In general they find low arterial carbon dioxide contents and normal or low normal capacities, except in severe congestive failure, more especially in cases of myocardial degeneration, when high arterial carbon dioxide contents appear to be the rule. There are no reliable figures in the literature for the hydrogen-ion concentration obtained by direct observation on the arterial blood and the calculated values are unreliable since they are calculated on pressure values obtained from curves constructed with venous blood The colorimetric method used in this series is not reliable, in that the factors that may be present in disease and may give rise to error are not yet known, but it gives values independent of the carbon dioxide determinations that have at least a comparative value in repeated observations on a single case Lewis and Barcroft[39] estimated the reduction in ' alkalinity ' or the excessive amount of fixed acid present by the oxygen saturation of the blood at 17 mm pressure of that gas. They found some degree of acidosis to be common in the cardiac dyspnœa of elderly or middle-aged patients and to be especially common in terminal heart failure Such a condition was well seen in Case 10 in this series The readjustment of base that takes place in the presence of low carbon dioxide tensions so that the carbon dioxide capacity or combining power is lowered would account in a further number of their cases for the apparent " acidosis ' obtained by their methods All these results by other observers are compatible with the results in this series when it which occurs under ordinary circumstances in the body, as opposed to the contraction produced by maximal stimuli The diaphragm offers an ideal muscle for such an investigation because the normal respiratory movement of one half can be employed as a pattern to the result of artificial stimuli to the cut phrenic of the opposite side. A very presentable imitation of the normal movement has been obtained by Lady Briscoe[18] by the following means —

Top row sections of diaphragm Lower row length of muscle fibre from attachment to insertion From left to right (1) from a point half way between nipple and mid sternal lines, (2) from mid axillary line, (3) from posterior axillary line, (4) from the top of the twelfth rib, (5) from the crus

Application of Theory to General Observations.

The same law of stretch explains the following phenomena observed clinically: 1. All conditions producing extension of the spine diminish the tension in the domes of the diaphragm and so increase the tendency to thoracic expansion by widening the intercostal space. Such are: (*a*) change from slack to upright by order deliberately or subconsciously in anger, anxiety, &c., (*b*) supine posture or reclining when the surface on which the back rests is flat.

2. All conditions increasing flexion of the spine increase the stretch in the domes and diminish the intercostal spaces and the tendency to thoracic expansion: (*a*) change *from upright to slack*, (*b*) reclining as in a hammock or similar arrangement. If the latter is pushed to the extreme the intercostals cease to contract at all and the spaces recede in inspiration.

3. Increased intra-abdominal pressure by gas or fluid will place the domes under stretch and promote contraction and diminish thoracic expansion.

4. With the back in a constant position, extension of the head increases the stretch of the anterior scalene, elevates the thorax, and produces an increased movement of the ribs (Fig. 5).

5. Lateral flexion of the spine increases the movement of the ribs on the convex side; the intercostal spaces are rendered wider and the muscles put on the stretch. Conversely on the concave side the spaces are narrowed, the muscular adjustment approximated, stretch is decreased, and the action diminished.

6. Elevation of the ribs by the intercostals increases the stretch on the transversalis, triangularis, and lateral abdominal muscles, and renders them receptive to expiratory impulses.

7. When these muscles contract in inspiration, and pull down the lower ribs, the lower intercostals are stretched and contract in expiration.

8. In the analysis of tracings of respiratory movements I find that the larger the contraction the earlier it appears to commence (Fig. 6).

The construction of the diaphragm is in accord with this theory, for where the shorter length of muscle from origin to insertion is found, there is the greater mass of muscle-fibres.[*] This is an optimum condition for efficiency on the basis of the stretch reaction.[¶]

Summary

The question of stretch then governs the order in which muscles will contract and the power they will put into that contraction. The diaphragm is almost the only respiratory muscle worth considering in quiet breathing in animals, and remains the most important in man, though in him it has lost some mechanical efficiency through his orthograde habit. Man is forced to compensate for this relative deficiency of the diaphragm by a greater use of other muscles, these other muscles acting either by active contraction or by persistent tonus of postural type. If exaggerated these actions are not a normal use of muscle but an abnormal over-use, and in consequence a possible source of trouble.

(*The bibliography, to which references are given in this lecture, will appear with the third lecture.*)

[¶] As a corollary, the varying length of muscle-fibre must lead to variations in stretch effect; the longer fibres will be the least influenced by a given stretch. The longest fibres of the diaphragm are those which originate in the axillary area, where also the bulk of muscle is least. I therefore think that these are the last of the diaphragm fibres to come into contraction, and the first to fail to contract. Such a conception is suggestive in relation to physical signs—e.g., of pleural effusion.

LECTURE III[*]

Causes of the Increased Ventilation.

The results of the examination of the arterial blood in these cases agree in general with those of other observers. In spite of using venous blood for the construction of the dissociation curve and so obtaining values for the carbon dioxide pressure that may err on the high side, Campbell, Hunt, and Poulton[20] found that while some cases of mitral stenosis with dyspnœa had low arterial carbon dioxide values, others had raised values with a fall in oxygen saturation. They found the carbon dioxide combining power about the lower limit of the normal, and the hydrogen-ion concentration within normal limits. The patients with arterial disease and myocardial degeneration investigated by them had more pronounced pulmonary complications than those in this series, and their findings in them were similar to those in the third group in this series. Peters and Barr[21] considered a carbon dioxide acidosis to be the cause of cardiac dyspnœa, but base their opinion on dissociation curves constructed with venous blood. Peters[38] found the alveolar carbon dioxide pressure to be low in comparison with the capacity of the venous plasma, and presumed that the hydrogen-ion concentration of the blood was raised. Peters and Barr,[21] and Campbell, Hunt, and Poulton[20] found that the carbon dioxide pressure in the arterial blood is higher than that in the alveolar air in severe failure. Several writers have reported on the arterial carbon dioxide content and on the capacity or combining power in heart failure, notably Harrop,[18] Barach and Woodwell,[19] and Meakins and Davies.[2] In general they find low arterial carbon dioxide contents and normal or low normal capacities, except in severe congestive failure, more especially in cases of myocardial degeneration, when high arterial carbon dioxide contents appear to be the rule. There are no reliable figures in the literature for the hydrogen-ion concentration obtained by direct observation on the arterial blood and the calculated values are unreliable, since they are calculated on pressure values obtained from curves constructed with venous blood. The colorimetric method used in this series is not reliable, in that the factors that may be present in disease and may give rise to error are not yet known, but it gives values independent of the carbon dioxide determinations that have at least a comparative value in repeated observations on a single case. Lewis and Barcroft[39] estimated the reduction in "alkalinity" or the excessive amount of fixed acid present by the oxygen saturation of the blood at 17 mm. pressure of that gas. They found some degree of acidosis to be common in the cardiac dyspnœa of elderly or middle-aged patients, and to be especially common in terminal heart failure. Such a condition was well seen in Case 10 in this series. The readjustment of base that takes place in the presence of low carbon dioxide tensions, so that the carbon dioxide capacity or combining power is lowered, would account in a further number of their cases for the apparent "*acidosis*" obtained by their methods. All these results by other observers are compatible with the results in this series, when it is seen that the condition of the patient at the time of the observation may determine whether a low carbon dioxide pressure is found, or a raised pressure due to the œdema and other changes in the lungs that occur in the very advanced stage of failure The important cases from the point of view of determining the essential factors in the dyspnœa are the younger ones, who are less likely to have disturbances due to arterial and renal disease or to pulmonary disease in addition to heart failure

---

[*] Lectures I and II appeared in The Lancet of March 12th and 19th respectively.

The stimulus to the respiratory centre, though independent of the quality of the arterial blood, may be the result of circulatory disturbances at the centre In heart failure the altered conditions of the circulation can result conceivably in changes in the tissues in two ways Slowing of the circulation so that the tissues receive less arterial blood may result in (*a*) a deficient supply of oxygen to the respiratory centre even though the blood contains a normal quantity of oxygen, and may result in (*b*) a raised carbon dioxide content and pressure in the venous and capillary blood, so that the tissues of the centre are exposed to a raised carbon dioxide pressure and increased hydrogen-ion concentration

The methods available for the estimation of the blood flow per minute are not yet suitable for the investigation of severely dyspnœic patients By practice, however, suitable patients can be trained to cooperate so that results of value are obtained The most satisfactory methods depend essentially on the estimation of the carbon dioxide pressure in the mixed venous blood from the pressure in the alveolar air when equilibrium with the blood in the lungs is established In practice this is a difficult procedure in a dyspnœic patient Barcroft, Bock, and Roughton [40] found a reduction in the minute volume of more than 50 per cent to occur in a case of paroxysmal tachycardia during the tachycardia Dautrebande, Fetter, and Meakins [22] found a similar reduction in a case of auricular fibrillation and mitral stenosis during an attack of severe tachycardia. Meakins and Davies [2] found in two cases of auricular flutter that the minute volume was reduced when the ventricular rate was increased In cases of mitral stenosis in which clinical evidence pointed to a considerable degree of stenosis the circulation rate was diminished. In two cases of syphilitic disease of the aorta with aortic regurgitation the minute volume was greatly reduced with the onset of congestive failure In one case of myocardial degeneration, an increase in the degree of failure was accompanied by a greatly reduced minute volume These results are sufficient to support the view that cardiac disability sufficient to produce dyspnœa at rest is accompanied by a reduction in the minute volume, and indicate that this reduction may be as much as 50 per cent or more

Peabody, Meyer, and Du Bois [41] have estimated the metabolism in cases of cardiac insufficiency with dyspnœa, and find that it is increased over the normal and that the increase may be as great as 25–50 per cent Their results have been confirmed by Hamburger and Lev,[42] and by Shapiro [43] Eppinger, Papp, and Schwarz [23] estimated the difference in the oxygen content of the arterial blood and of the blood from the arm veins in normal subjects and in cases of different types of dyspnœa In cases of heart failure with valvular disease they found a pronounced increase in the amount of oxygen extracted by the tissues from a given volume of blood in the majority of cases This increased utilisation was more marked in cases of mitral valve disease than in cases of aortic valve disease They point out that blood from the arm veins does not necessarily give a true indication of the general circulation In cases of dyspnœa with high blood pressure and heart failure they did not find evidence of increased utilisation

In cases of heart failure, therefore, such as those we have investigated, there is evidence to show that there is a raised metabolism and at the same time a diminished blood-supply to the tissues This condition will result in an increased utilisation of the oxygen in the arterial blood by the tissues From the shape of the dissociation curve of oxyhæmoglobin,[25] the increased volume of oxygen that the blood gives up in its passage through the tissues must be supplied at a mean pressure that is lower than normal Since, presumably, the tissues of the respiratory centre will be affected in common with the other tissues of the body, the centre also will receive its oxygen at a lowered pressure The centre will thus be stimulated and hyperpnœa will result At the same time the venous blood must be carrying an increased load of carbon dioxide, and the carbon dioxide pressure in the venous and in the capillary blood will be increased The reduction in the carbon dioxide pressure in the arterial blood in consequence of the increased ventilation due to the oxygen deficiency will to some extent compensate for this, as Pearce [44] has shown In cases with unhampered ventilation and efficient gaseous exchange this compensation may be sufficient, but in cases with pulmonary disease or with severe secondary changes in the lungs, there will probably be an additional stimulus to the centre in the raised carbon dioxide pressure at the centre If this was a constant factor in cardiac dyspnœa, one would expect, from the observations of Henderson and Haggard,[13] that the carbon dioxide capacities would be high, at any rate in young subjects without evidence of renal disease and in the less severe stages of failure In this series a raised carbon dioxide pressure in the arterial blood in young subjects is accompanied by a raised combining power or capacity (see Cases 5 and 17), but many of our cases of cardiac dyspnœa in otherwise comparable subjects have low capacities It is unlikely, therefore, that in them there is a raised carbon dioxide pressure in the tissues

Conclusions on Increased Ventilation

It appears, therefore, that (1) one constant stimulus to the respiratory centre in cardiac dyspnœa to produce increased ventilation is a deficient supply of oxygen, due to a diminished blood-supply to the centre , (2) in cases with pulmonary disease in addition, and cases of severe failure with pronounced secondary changes in the lungs, raised carbon dioxide pressure and increased hydrogen-ion concentration will act as an additional stimulus , and (3) in cases near death or in very advanced conditions of failure the retention of non-volatile acid substances will result in an increased hydrogen-ion concentration that will act as an additional stimulus In some cases under (2) and (3) a low oxygen saturation in the arterial blood may be present, and this will be a further factor in the stimulation of the centre

RESPIRATORY DISTRESS

In any explanation of cardiac dyspnœa it is not sufficient to show that the respiratory centre is stimulated, and that in uncomplicated cases the study of the arterial blood shows that there is hyperpnœa and increased ventilation To account for the dyspnœa it is necessary to show that the need for increased ventilation is greater than the pulmonary apparatus can meet easily and without the respiratory action entering the field of consciousness and so producing distress The factors that may interfere with efficient pulmonary ventilation have been fully discussed by Means[1] and Meakins and Davies [2]

Vital Capacity

In quiet, healthy breathing the amount of air that is inspired and expired at each respiratory cycle is about 500 c cm This is called the tidal air The amount that can be forcibly expired after a forced inspiration is between four and five litres This is called the vital capacity, and is divided into the complemental air which is the amount that can be forcibly inspired from the mid-position, and the reserve air or the amount that can be forcibly expired from the mid-position After a forcible expiration there is still a considerable volume of air in the lungs, called the residual air The tidal air can be greatly increased without dyspnœa arising, and Peabody [45] showed that if hyperpnœa is induced by breathing increasing concentrations of carbon dioxide, the tidal air may be increased 400 per cent. before distress becomes marked. The actual increase before the onset of distress varies considerably with individuals. Means and Balboni[46] showed that if the vital capacity is reduced *by half in artificial pneumothorax*, the tidal air increases with increasing concentrations of carbon dioxide as in the normal, but that dyspnœa appears much earlier. It is evident, then, that the relation of tidal air to vital capacity is important in determining the onset of dyspnœa. Vital capacities in healthy individuals have been carefully studied, and Dreyer's[47] conclusion that it is a simple function of the area of the body surface is generally accepted. The vital capacity in cases of congestive heart failure has been studied by Siebeck,[48] by Bittorf and Forschbach[49] and by Peabody and Wentworth.[50] They find a very constant reduction in vital capacity, which may be as low as one litre. Further, Peabody and Wentworth followed cases from stages of severe failure to those of comparative recovery, and found that as recovery occurred the vital capacity rose. The reduction of vital capacity affects the reserve air more than the complemental. To ascertain the cause of the reduced vital capacity, Drinker, Peabody, and Blumgart[51] carried out animal experiments. They concluded that the loss of elasticity of the lungs that results from congestion is the main factor, and that the greater the pressure in the pulmonary circuit the less the vital capacity. They point out that the actual enlargement of the heart and the increased quantity of blood in the pulmonary vessels must reduce somewhat the air-containing space in the thorax. The onset of œdema of the lungs and of fluid in the pleural cavities as extreme failure sets in will still further reduce the vital capacity. That a reduction in vital capacity is an essential factor in the production of cardiac dyspnœa is supported by the examination of the arterial blood in two cases of active heart disease who were without any respiratory distress when lying flat in bed. Case 20, aged 38, had subacute bacterial endocarditis with aortic regurgitation and mitral valve disease. The heart was dilated and there was œdema of the legs and a few râles at the bases of the lungs. Case 21 had active rheumatic carditis with aortic regurgitation and mitral disease, and the heart was dilated. The results of the examination in these cases are shown in Table VIII. The normal oxygen saturation, low carbon dioxide tension, and volumes with low normal capacities, and values for the calculated pH in the alkaline half of the normal range are similar to those found in the younger patients with mitral stenosis and auricular fibrillation and severe dyspnœa. The character of the arterial blood indicates increased ventilation therefore in both the dyspnœic patients and in Cases 20 and 21. The patients with dyspnœa differed from those two cases apart from the presence of respiratory distress, in that they had a high colour and more or less cyanosis indicative of some degree of venous engorgement. It is probable, therefore, that the incidence of the dyspnœa was determined by the reduction of vital capacity due to pulmonary vascular engorgement. The mechanism of heart failure in cases of mitral stenosis differs from that in cases of high blood pressure and myocardial degeneration in that pulmonary engorgement occurs at a much earlier stage in the failure, and this has most likely a causal relationship with the early incidence of dyspnœa in mitral stenosis, and its later incidence in cases of myocardial degeneration and high blood pressure when the stage of advanced failure is reached. It would appear, therefore, that the effort necessary to effect the required ventilation in the presence of the reduced vital capacity is a factor in bringing the respiratory act into the field of consciousness and producing distress.

TABLE VIII.

Result of examination of arterial blood in two cases of acute valvular disease without evidence of dyspnœa or heart failure at rest.

Case No	Age	Date in 1924	Dyspnœa at rest	Arterial blood.

V % = Volumes per cent

Shallow Breathing.

The type of breathing in cardiac dyspnœa is rapid and shallow as a rule. The chemical stimuli at the centre regulate the amount of alveolar ventilation, and when it is considered that the presence of a considerable dead space in the upper respiratory passages and bronchial tree must result in waste each time this space is filled and emptied, it is obvious that the deeper and fewer the respiratory movements are the more economical they will be in establishing the required ventilation. The type of breathing is normally regulated by the Hering-Breuer reflex. Afferent stimuli from the lungs are conveyed to the centre by the vagus nerves, so that when inspiration has proceeded to a certain extent, the inspiratory movement is inhibited and expiration takes place. Means[1] considers that the respiratory centre and the vagus inhibition are so regulated in health that a happy medium exists between slow deep breathing and rapid shallow breathing. Slower and deeper breathing would involve active respiratory efforts to expel some of the reserve air, and so lead to greater exertion than is necessary when normal tidal respiration with its passive expiratory phase is occurring, while shallower respiration by increasing the importance of the dead space would cause more rapid breathing and augment the work of the respiratory musculature in effecting the necessary alveolar ventilation. It is conceivable that some exaggeration of the vagus inhibition relative to the activity of the respiratory centre can bring about the shallow rapid form of breathing seen in cardiac dyspnœa. Haldane, Meakins, and Priestley[5] showed that shallow and correspondingly frequent breathing resulted from long continued oxygen want, and considered it due to fatigue of the centre. Davies, Haldane, and Priestley,[52] showed that this type of breathing resulted as a response to excessive and prolonged resistance. The rapid and shallow character of the breathing in cardiac dyspnœa may be the result, then, of fatigue of the centre and a relative exaggeration of the vagus inhibition of the inspiratory act, but the appearance of this character comparatively early in the course of mitral stenosis points to the mechanical limitation of expansion and reduction of vital capacity consequent on the vascular engorgement as the more important factor. In the later stages of failure gross œdema of the lungs will still further limit the depth of breathing, and the fatigue of the centre, due to anoxæmia and increased resistance, must undoubtedly add its effect. That shallow breathing can cause anoxæmia has been demonstrated by Haldane, Meakins, and Priestley.[53] A vicious circle will thus be established, and a dangerous and urgent stage of failure will be reached. The rapidity of the breathing that accompanies the shallowness in order to effect the necessary ventilation is probably a factor in causing consciousness of the respiratory movements and distress.

Conclusions on Respiratory Distress.

The slow circulation rate of heart failure which results in a stimulus at the centre for increased ventilation results therefore, at the same time in reduction of vital capacity by engorgement of the pulmonary circulation and in fatigue of the respiratory centre, so that the need for increased ventilation cannot be met without consciousness of the respiratory movements This produces distress or dyspnœa

ORTHOPNŒA

In all the cases of cardiac dyspnœa studied by us orthopnœa was present as well. There is evidence to show that this also is closely related to reduced vital capacity Christie and Beams[54] have shown that orthponœa only occurs when the vital capacity is reduced. Haldane, Meakins, and Priestley[5] believe that the fan-like expansion of the lung is less efficiently carried out in the lying than in the upright posture, and showed that constriction of the abdomen and thorax so as to limit the inspiratory movement caused less discomfort in the upright than in the lying posture If the breathing is of the rapid shallow type from respiratory fatigue, anoxæmia results more readily in the recumbent than in the upright posture The suggested explanation for the dyspnœa, therefore, accounts also for the orthopnœa

PERIODIC BREATHING

In two cases in this series Cheyne-Stokes' breathing occurred In Case 10 (see Tables III and VI) no periodicity was observable at the time of the first observation, but was obvious on the previous day. In Case 12 the periodicity was so pronounced at the first observation that the blood was obtained entirely during a period of hyperpnœa At the second observation it was still present, but was much less pronounced, and the time during which the arterial blood sample was withdrawn included both the phase of hyperpnœa and the phase of reduced respiratory movements The work of Douglas and Haldane,[55] and of Pembrey and Allen,[56] has demonstrated conclusively that this type of breathing is due to oxygen want at the respiratory centre The centre, therefore, functions about a lowered threshold of carbon dioxide pressure[4] Our results are quite compatible with this view, as the examination of the arterial blood shows merely the effects of hyperpnœa not due to oxygen unsaturation or carbon dioxide excess in the arterial blood Clinically, periodic breathing is rarely observed in cases of heart failure with marked stasis and venous congestion in which pulmonary ventilation is mechanically hampered, and is found most commonly in cases of arteriosclerosis or of raised intracranial pressure before the late congestive stage of failure is reached The precise relations of the circulation at the centre, and the oxygen and carbon dioxide pressures necessary to produce this rather uncommon respiratory disorder are still undecided. To account for the peculiar features of this type of respiration, for the experimental observations, and for its clinical incidence, it would appear that two conditions must be satisfied (1) the respiratory centre because of oxygen lack must be functioning about a lower threshold of carbon dioxide and hydrogen-ion concentration than normal and more sensitive than normal to variations in these factors; and (2) the pulmonary apparatus must be capable of considerable increase in alveolar ventilation, permitting the carbon dioxide pressure in the arterial blood to be readily lowered, and the carbon dioxide pressure at the centre to undergo considerable variations.

PAROXYSMAL DYSPNŒA

Cases 9, 11, and 16 in the present series were liable to attacks of paroxysmal dyspnœa of the type known as cardiac asthma At the second observation on Case 9 the arterial blood was taken during such an attack, but as the attack occurred at the onset of erysipelas which proved fatal, and at the time of the rapidly increasing fever of onset, the results cannot be regarded as typical In the other cases the observations were not made at the time of the paroxysms The recent work of Eppinger, Papp, and Schwarz,[23] on the condition of the circulation during attacks of cardiac asthma, and after relief by means of morphia, are of great interest and importance They employed several methods for estimating the circulation rate, and came to the conclusion that in a number of cases the minute volume of the circulation is increased above the normal during the paroxysm, and that it becomes less in recovery after the use of morphia This is a surprising observation and deserves careful consideration Paroxysms of cardiac asthma are accompanied by great distress and violent respiratory efforts Râles of pulmonary œdema are present and increase in number as the paroxysm continues, and the patient becomes cyanosed and may die Morphia stops the attacks and the râles diminish and disappear as the dyspnœa lessens Since cardiac asthma is not seen commonly in heart failure, there must be some causal factor in addition to the presence of heart failure with a slow general circulation rate, and in view of the findings of Eppinger, Papp, and Schwarz that the paroxysms continue in spite of a raised circulation rate, this causal factor must be independent of the general circulation rate Hofbauer[57] has suggested that local spasm of the arteries supplying the respiratory centre is the cause of the paroxysm, and quotes the frequency of arterial spasm in cases of cardiorenal disease in which this type of dyspnœa is most commonly seen, in support of the hypothesis The increasing cyanosis, the increasing pulmonary congestion, the raised circulation rate and the improvement after morphia, are not explained by this hypothesis Blalock, Harrison, and Wilson[33] have shown experimentally that in morphinised dogs obstruction to the respiration sufficient to produce anoxæmia caused the minute volume of the circulation to be much increased Harrison and Blalock[58] showed that in dogs trained so that the use of morphia was unnecessary, severe anoxæmia produced by breathing air poor in oxygen was accompanied by an increased cardiac output Huggett,[59] working with cats, found that obstruction to inspiration caused an increase in minute volume and stroke volume of the circulation, but that obstruction to expiration caused a diminution These experimental results suggest that inspiratory efforts in the presence of mechanical difficulties in the carrying out of the inspiratory act result in an increased blood flow to the heart through the action of the respiratory pump A flow of blood to the right heart and thence to the pulmonary circulation that is too great for the left ventricle to handle will result in an increased circulation rate and in increasing œdema of the lungs So long, therefore, as inspiratory effort and inspiratory difficulty continue in a case in which the left ventricle is working nearer the limit of its capacity than the right increasing pulmonary œdema may be brought about. The type of case in which cardiac asthma occurs is usually the cardiorenal or arterio-sclerotic, with signs of heart failure, and in this type the main stress falls on the left ventricle Whether the onset of the paroxysm is due to local vascular constriction at the centre, or whether it is due to the development of congestion and œdema of the bases of the lungs from the recumbent posture of the patient, or from the lack of conscious respiratory effort during sleep, or whether it is due to some sudden disablement of the left ventricle, such as coronary thrombosis or an abnormal rhythm, is uncertain Any of these possible causes of the onset of vigorous respiratory efforts will result, first, in the circulation rate being raised to the extent that the left ventricle is capable of, and then, if the left ventricle was previously working nearer to its maximum capacity than the right, in pulmonary œdema

If this is the explanation of the features of cardiac asthma, the relief obtained by morphia and the accompanying slowing of the circulation rate, noted by Eppinger, Papp, and Schwarz, are understandable Morphia acts on the respiratory centre to depress it, and will check the inspiratory efforts so that the blood flow to the heart is lessened, and the muscle of the left ventricle will have a chance to recover sufficiently to re-establish the balance between right and left ventricular output and to remove the immediate and urgent danger

Dyspnœa Possibly a Dangerous Reaction

The analysis of the different types of dyspnœa in heart failure points to the conclusion that, although the increased ventilation is of service to the body in that it tends to correct oxygen lack in the tissues and to restore carbon dioxide pressure and hydrogen-ion concentration in the tissues to normal values if these also are disturbed, respiratory efforts in the presence of resistance to the inspiratory expansion will be a source of urgent danger if the left ventricle is already working near its maximum capacity. Severe dyspnœa with increasing pulmonary œdema should, therefore, be immediately checked by the use of morphia. It is probable, as Wilson[60] has suggested, that in many cases with less urgent indications the use of morphia would be of more value than is usually realised. It has, however, serious drawbacks. The increased ventilation will be checked and the oxygen saturation of the arterial blood may thus be diminished and the tissue anoxæmia increased or the carbon dioxide pressure and hydrogen-ion concentration of the arterial blood and of the tissues may be unduly raised. These dangers were seen in Case 15, in which morphia was administered on two occasions. Table IX shows the results of the examination of the arterial blood before and after the administration of the morphia. On the first occasion an eighth of a grain was given, and the oxygen saturation dropped from 100 per cent to 80 per cent, and the carbon dioxide content and pressure rose, while the patient experienced great relief and showed no apparent ill-effects of the anoxæmia. On the second occasion the dyspnœa was less, and a sixteenth of a grain was given. There was again considerable relief but less striking than on the previous occasion, and the arterial blood showed no significant changes. Anoxæmia to the extent seen in this case after an eighth of a grain of morphia might well be fatal if the centres were already fatigued, and much caution is necessary before deciding to check dyspnœa in this way. Such a procedure would have a more general application if oxygen could at the same time be effectively introduced and supplied to the tissues. The present methods of oxygen therapy are not satisfactory, and more efficient and practical methods of administration are urgently needed. Such methods would be of inestimable value in permitting an extension of the use of morphia in the treatment of heart failure.

TABLE IX

Effect of morphia on the dyspnœa and the characters of the arterial blood in Case 15

Date in 1926	Morphia	Dyspnœa	Arterial blood

Whatever may be the value of treatment directed to the removal of a dangerous reaction, the basic fault in all forms of cardiac dyspnœa, as this analysis has shown and as Means[1] and Meakins and Davies[2] point out, is the inefficiency of the heart muscle, and treatment must be directed primarily to improving the efficiency of the myocardium and to diminishing the work that it is called upon to perform.

SUMMARY AND CONCLUSIONS

1. The study of the arterial blood in cases of cardiac dyspnœa shows the presence of factors producing increased ventilation or hyperpnœa, and indicates that (1) The one constant stimulus to the respiratory centre in cardiac dyspnœa to produce increased ventilation is a deficient supply of oxygen due to a diminished blood-supply to the centre. (2) In cases with pulmonary disease in addition and cases of severe failure with pronounced secondary changes in the lungs, raised carbon dioxide pressure and increased hydrogen-ion concentration will act as an additional stimulus. (3) In cases near death or in very advanced conditions of failure, the retention of non-volatile acid substance will result in an increased hydrogen-ion concentration that will act as an additional stimulus. (4) In some cases under (2) and (3) a low oxygen saturation of the arterial blood may be present and this will be a further factor in the stimulation of the centre.

2. There is evidence that the slow circulation rate of heart failure which results in the stimulus at the centre to produce increased ventilation, results at the same time in reduction of vital capacity by engorgement of the pulmonary circulation and in fatigue of the centre so that the need for increased ventilation cannot be met without consciousness of the respiratory movements. This produces the distress of dyspnœa.

3. The clinical features and experimental observations on orthopnœa, periodic breathing, and paroxysmal dyspnœa (or cardiac asthma) are compatible with these conceptions of cardiac dyspnœa.

4. Dyspnœa may be a dangerous reaction, and in certain cases the direct treatment of it by means of morphia is indicated but full use of this action of morphia cannot be attained until practical methods of administering oxygen are further developed.

5. The fundamental cause of cardiac dyspnœa is inefficiency of the myocardium.

In conclusion I should like to express my indebtedness to the skill and cooperation of my colleagues, whose work has given me the opportunity of carrying out this analysis and discussion.

SANOCRYSIN IN THE TREATMENT OF PULMONARY TUBERCULOSIS

By ANDREW MORLAND, M B, B.S Lond,
MEDICAL SUPERINTENDENT OF PALACE SANATORIUM, MONTANA, SWITZERLAND,
AND
ERIC ZIMMERLI, M D. Basle, M R.C S. Eng.,
FIRST ASSISTANT

Following Prof Mollgaard's discovery three years ago,[1] that sanocrysin, when given sufficiently early and in adequate amount, exercises a strikingly beneficial effect on tuberculous lesions in calves, there has been a large amount of work in the clinical field, and although the results of this have not been uniform, there is much evidence to show that in this salt of gold we have a drug with a definitely specific action on the tuberculous process

The great majority of cases on which this article is based had failed to give satisfactory response to sanatorium treatment, the prognosis was at best doubtful and in several cases definitely bad. It is too early to say how far the ultimate prognosis has been affected by the sanocrysin treatment, but in a number of cases febrile, sputum positive, more or less bedridden patients have changed during or following the course of injections into afebrile, sputum negative, ambulant cases After a certain number of weeks or months there is a tendency for the sputum to become positive again, and, less commonly, for the temperature to rise; a second course of injections usually results in these symptoms disappearing again

Selection of Cases

Since fibrous tissue hampers the action of a drug circulating in the blood stream, cases of long-standing phthisis with cavities and much fibrosis cannot be expected to do as well as those in which the disease is early and the tuberculous infiltration soft and in close contact with the blood capillaries The first cases chosen were, therefore, chiefly of the latter type As some of these gave strikingly good results there was a general demand for the treatment among their fellow patients, and recently a number of less suitable cases have been treated and we have found that even in disease of many years' duration marked improvement may occur In two cases in the last stages of cachexia and emaciation sanocrysin was tried at the request of the patient and relatives, but it was not found possible in either case to maintain a sufficient dosage to have any lasting effect The most severe case to have a good result differed from these in that he was gaining weight at the time sanocrysin was started, he lost seven pounds during the following six weeks This question of emaciation is most important in the selection of cases as, unless the patient is thought fit to stand the loss of several pounds, it will probably be found necessary to abandon treatment with the disease still active and the patient even more emaciated than at the beginning of treatment

Artificial Pneumothorax and Sanocrysin

As Gravesen has already observed,[2] there are many cases in which collapse treatment may with advantage be combined with sanocrysin A typical example of this was seen in a case in which recent disease in the uncollapsed lung became inactive after a few weeks' gold treatment In another case a pneumothorax which had successfully controlled activity for some months obliterated gradually after pleural effusion The first stage of this process resulted in the re-expansion of the whole lung with the exception of the apex; activity, manifested by fever, positive sputum, and coarse râles returned, but was temporarily checked by a course of sanocrysin Several weeks later the apex, which contained a large cavity, re-expanded and the symptoms of activity returned, but disappeared again with a second course of gold This patient has been free from active symptoms for three months.

Dosage

No hard-and-fast rules can be laid down as to the dosage Careful individualisation will give better results than any rigid system In the early days of sanocrysin large doses at short intervals were given from the beginning of treatment[3]; severe shock and sometimes fatal reactions resulted and the method was looked on by many as a "kill or cure" treatment Our experience suggests that equally good results can be obtained without exposing the patient to such dangers The aim of the treatment should be to obtain an effective concentration of the drug in the body without, in so doing, producing reactions so severe as to endanger life or reduce the resistance to the disease In our cases the initial dose has varied between 0 025 g in an emaciated subject with advanced disease and 0 35 g in an ambulant case In the former it was 40 days before a dose of 0 75 g. could be given, while in the latter 0 6 g was given on the second day and 0 85 g on the fifth As a general rule, 0 85 g to 1 g has been considered a full dose for adult males In females it is often better not to give more than 0 75 to 0 85 g

Wk. = Walking m = miles.

After a moderate reaction—i e, a rise in temperature of 1°–2° F—the dose should not be increased at the next injection After a severe reaction temperature rise of 3°–4°, or when there is marked albuminuria or a rash, the interval should be increased and the dose diminished The question of dosage is complicated by the fact that although the tolerance to the drug tends to increase, this may be more than counterbalanced by cumulative action as excretion is slow

The blood sedimentation test is of some value in confirming the clinical impression of the degree of toxæmia The rate of sedimentation tends to become more rapid during treatment, but subsequently rises to more normal figures. Rapid sedimentation, and particularly a sudden increase in the rate of sedimentation, is an indication for caution In severe cases it is often better to give doses of 0 1 g daily,[4] or 0·25 g on alternate days rather than to attempt to give larger doses at longer intervals

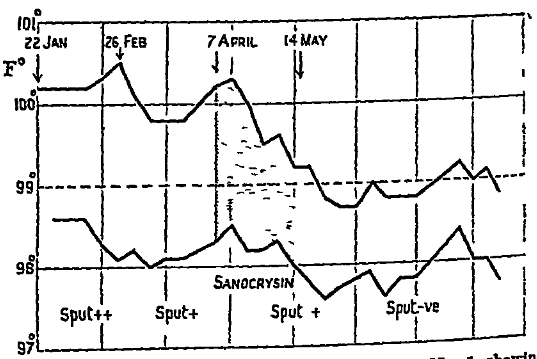
It has been usual to give a total of 6–8 g as a first course, and then to wait about three months before giving a second course of 4–5 g A more rational procedure is to continue to give the maximum dose until the patient has ceased to react Mollgaard has shown that healthy animals show no temperature reaction, even with large doses of sanocrysin[5] In treating tuberculous subjects, the most severe reactions usually occur with the first few doses or with the first full dose, subsequently they tend to diminish and finally to disappear. The total amount of gold salt which has to be given before the patient's temperature ceases to be affected has varied in our cases from 2 or 3 g to more than 10 g During the second course temperature reactions are rare, and 4 to 5 g seems to be a sufficient amount in the majority of cases

Reactions

The most dreaded reaction of sanocrysin treatment is *shock.* This is similar to the tuberculin shock produced experimentally on animals, and is characterised by albuminuria, subnormal temperature, and weak pulse This reaction has not been observed in any of our cases; it is true that the majority have had transitory albuminuria at some time during treatment, this has never lasted more than a few days It has always been looked on as a signal of possible danger, and no further injection has been given until the last trace has disappeared; the dose is never increased for the next injection, nor is the interval shortened As observed by Faber,[6] an *early* and a *late* type of albuminuria have to be distinguished in sanocrysin treatment. The former never occurs in non-tuberculous animals treated with sanocrysin, and its duration may be shortened by injections of antituberculous serum Late albuminuria, on the other hand, runs a much more protracted course and is of quite unknown origin Early albuminuria was generally considered to be toxic in origin and closely associated with shock, but recent work[7] has shown that the majority of human cases presenting this symptom have no tendency to shock, and that serum injections have no effect on the duration of the condition Frandsen[8] has recently studied the effect of sanocrysin injections on the kidneys of healthy rabbits He finds that amounts considerably in excess of the largest therapeutic dose can be given repeatedly without the least damage to the kidney. Only when very large doses are given over a very long period are changes reminiscent of arterio-sclerotic kidney produced This is in sharp contrast not only with the changes observed in poisoning with other heavy metals, but also with the post mortem findings in patients dying from shock in sanocrysin treatment in which parenchymatous changes are invariable The late protracted type of albuminuria has never been observed in our cases

Rise of temperature has been constant during the early stages of treatment. By beginning with small doses and increasing gradually we have been able to avoid severe degrees of hyperpyrexia Temperatures of 103° or more have only been observed in two or three cases in which severe skin reactions were also present These temperature reactions, like the albuminuria, may be divided into an early and a late type In the former the rise of temperature tends to be sudden and reaches its maximum within a few hours of the injection; it is usually lower on the following day, but not infrequently may be higher on the second night, after which it comes down by lysis during the next few days The late temperature reactions are much less common and usually occur five to seven days after the injection, the rise is more gradual than in the early type and the temperature remains above normal for a week or ten days Both types of temperature reaction are associated with an increase in the amount of sputum and auscultation over the lesion usually shows an increase in the moist sounds present In three cases the late temperature reaction was associated with the reappearance of T B in the sputum which had become negative during the earlier stages of treatment

CHART 1



Rectal temperature record (Fahrenheit) of Case No 1, showing the weekly average reading of morning temperature (bottom line) and evening temperature (top line) The vertical lines mark four-weekly periods

Skin Reactions.

These are among the most serious inconveniences of treatment Severe morbilliform rashes followed by desquamation or even weeping eczema and associated with high temperature have only occurred in five of our cases This complication necessitated a break of several weeks in the treatment Slight skin reactions in the form of scattered papules or localised rashes on the elbows or knees have been more frequent It is impossible to tell at first whether these rashes are trivial and transitory or whether they are the first signs of a severe reaction, it is therefore advisable to proceed with great caution as soon as a skin reaction appears Ulcerative stomatitis has been noted in five cases and necessitated an interval of 10 to 14 days as the amount of ulceration immediately increases even if a reduced dose is given after the usual interval

Nausea and vomiting and occasionally diarrhoea are complications which tend to occur towards the end of treatment when large doses of gold are given A metallic taste is often noticed during or immediately after an injection, this may be closely followed by nausea and vomiting

Loss in weight is a very variable phenomenon; some patients actually gain during the course of treatment while in others as much as a stone has been lost in two months Considerable light has been thrown on the nature of the reactions observed in sanocrysin treatment by the recent work of Madsen and Morch in experimental tuberculosis[9] These investigations show that when an attenuated culture is used for infection the disease may be healed by means of gradually increasing doses of sanocrysin, should large doses be given early in treatment violent reactions and fatal shock result Virulent strains, on the other hand, require to be treated with large doses from the start, severe reactions do not occur, yet the disease is arrested in the great majority of cases

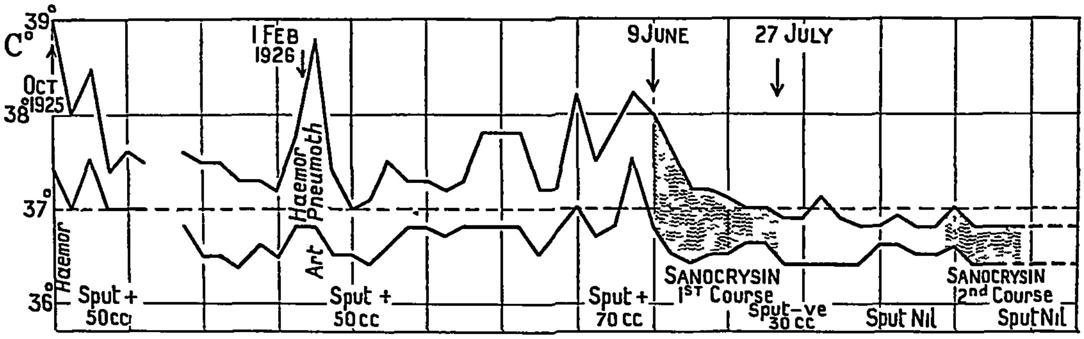
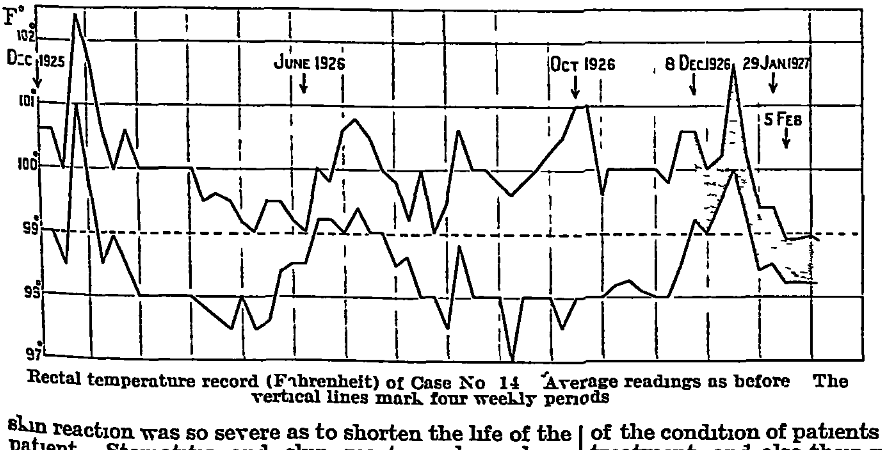
CHART 2



Mouth temperature record (Centigrade) of Case No 2 Average readings as before The vertical lines mark four weekly periods

We have not had the opportunity of treating a really virulent infection with sanocrysin, but our observations seem, on the whole, to accord with the animal experiments of Madsen and Morch It is, of course, very difficult to form an accurate opinion on the virulence of the strain affecting any particular patient since the clinical picture observed is the resultant of the virulence of the bacillus and the resistance of the body We have, none the less, noted that patients who appear to be thoroughly overcome by the disease to which they offer little resistance rarely have severe reactions An exception to this rule is seen in the case in whom the skin reaction was so severe as to shorten the life of the patient Stomatitis and skin reactions have been relatively more frequent in patients with good powers of resistance Severe skin reactions have never been observed in a second course of treatment, but stomatitis has been more frequent than in a first course

CHART 3



Rectal temperature record (Fahrenheit) of Case No 14 Average readings as before The vertical lines mark four weekly periods

Results

Every aspect of medicine has its difficulties in diagnosis, prognosis, and treatment, but none of these involves such problems as the decision as to whether a certain treatment is having a beneficial effect on a patient or whether the improvement observed is unconnected with the treatment or even in spite of it In no disease could this problem be more difficult than in tuberculosis in which improvement, temporary or permanent, occurs in the great majority of cases treated in a sanatorium The following table is therefore given with all reserve and with the knowledge that the figures given cannot pretend to scientific accuracy but merely represent our clinical judgment on the case involved In all 37 cases have been treated with sanocrysin; seven of these are not included in the following table because they are still under treatment, because the diagnosis of tuberculosis is uncertain, or because (in one case) treatment was soon abandoned owing to the neurasthenic condition of the patient

Class		
1	Improvement considered to be due at least partly to sanocrysin	17
2	Improved but doubtful if due to sanocrysin	8
3	Not improved	2
4	Died	3
		30

The 17 cases in which the improvement is attributed to sanocrysin include 14 in which the disease had reached the stage of cavity formation

In a number of these cases the improvement in the physical signs was so rapid that it is difficult to believe that it could have been effected without the help of sanocrysin This improvement was confirmed in several cases by X ray examination which showed the disappearance of soft infiltration in a relatively short time Fibrous tissue appears to be little affected

In the tabular statement an attempt is made to give some impression of the condition of patients before and after sanocrysin treatment, and also their subsequent history It will be seen from the table that out of 25 cases with tubercle bacilli in the sputum before treatment 19 became negative during the course of injections

Illustrative Cases

CASE 1—Male aged 28 Hæmoptysis two and a half years ago, but continued work Sputum T B plus, April, 1925 In bed almost continuously since then Arrived Montana Jan 22nd, 1926 Signs of severe and widespread disease both lungs with several cavities Much emaciation. Blood pressure, systolic, 80, diastolic, 55 Much sputum, T B plus Temperature shown on Chart 1 6 85 g gold given between April 7th and May 14th, 1926 Temperature normal, sputum negative, and much reduced in amount. Up all day and walking six miles by June Sputum again positive in July, but second course of gold followed by negative sputum Went home for two months, but cough and sputum increased After third course temperature again normal, but still some sputum T B plus Blood pressure, 120/90

---

[9] Madsen and Morch Traitement par le Sanocrysin de la Tuberculose Expérimentale, Acta Tub Scand, vol. ii, Fasc 2

CASE 2 —Female aged 23 Dry pleurisy June, 1925 November, 1925, cough, sputum T B plus Large cavity *right upper lobe January, 1926*, large hæmoptysis, for which right artificial pneumothorax induced Temporary improvement, but pneumothorax obliterated following pleural effusion, sputum T B plus Sanocrysin started June, 1926, 6 5 g given. Temperature rapidly came down to normal (Chart 2) Sputum negative, five weeks later no sputum Second course of sanocrysin ten weeks after first Now very well Gained 25 lb

CASE 30.—Female aged 22 Caseous pneumonia left upper lobe June, 1925 Arrived Montana October, 1926 Physical signs and X ray showed left upper lobe replaced by cavity, lower lobe extensively diseased Slight infiltration spreading *horizontally from right hilum* Bad prognosis given, but left artificial pneumothorax started Nov 24th Temperature came down from 100°–102° to almost normal during following week, but rose again *to 99° morning and 100° evening* a few days later Signs in right lung more definite Sanocrysin (0 1 g) started Dec 3rd Temperature normal from Dec 17th to 21st, and sputum almost stopped Dec 22nd beginning of rash (after 0 6 g gold) which took the form of a weeping eczema over the whole body Temperature 102° to 103 6° *Injections of Mollgaard's serum without effect* Death Jan 1st, 1927

CASE 14 —Female aged 39 Arrived Montana Dec 20th, 1925 Left upper lobe replaced by cavity, extensive infiltration *lower lobe* and scattered disease in right lung Bad prognosis given, but absolute rest, mostly out of doors on wheeled bed, for one year caused slight improvement on the whole, but still febrile and sputum abundant Sanocrysin started Dec 9th, 1926, small doses given, 0 1 g , increasing gradually to 0 6 g *Temperature came down* almost to normal (Chart 3), sputum much diminished, and great improvement general condition

Conclusions

1 The dangers of sanocrysin treatment have been greatly exaggerated With careful individualisation, gradually increasing doses and attention to reactions the treatment should only very rarely cause harm

2 The large proportion of T B positive cases which became negative (if only temporarily) and certain cases with fever of long duration which became afebrile point to a specific effect of the drug on the tuberculous process

3 Whereas sanocrysin may be of benefit in any case which has not reached an advanced stage of *emaciation*, the likelihood of benefit increases as the case approaches the early and pneumonic type and diminishes with the long-standing fibrotic type

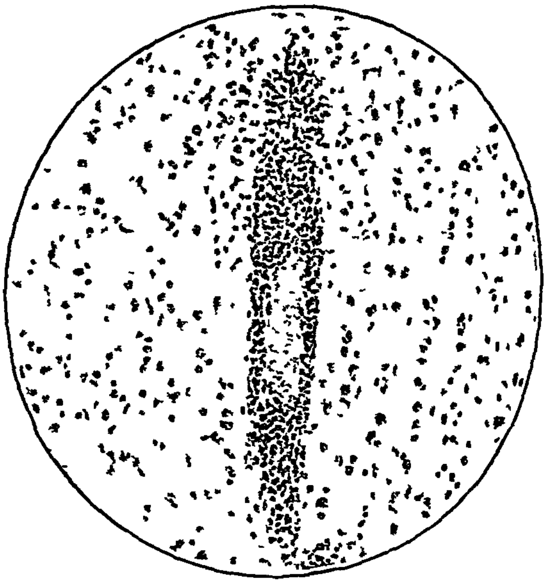
4 The animal experiments of Madsen and Morch suggest that the clinician would be helped considerably if he knew the virulence of the strain of tubercle bacillus affecting each patient. There is a need for close cooperation between physician and pathologist on this point

5 Although it is probable that sanocrysin has a specific action on tuberculosis, it is still far from being a " cure " for the disease The benefit derived is, in a number of cases, only temporary The striking success obtained in certain cases in the early days of sanocrysin *treatment with the use of large and often* dangerous doses led to the belief that it was desirable *to attempt to* sterilise the tissues completely in the course of a few weeks Similar claims were *made by* Ehrlich *in the early days* of salvarsan treatment and the *following* reflexion seems natural *If it is now* found that long specific treatment is necessary, even in early cases of syphilis, surely it is too much to expect that tuberculosis will be easier to cure and that a shorter time will be sufficient Mollgaard's calves were treated within about a fortnight of infection and gave results *comparable* with those obtained in the arsenical treatment of primary syphilis The fact that we cannot get as good results in human cases of much longer standing gives no occasion for pessimism, but encourages us to direct our attention to evolving a more satisfactory system of doses which will enable us to derive more benefit from a drug which has already given favourable results

EXPERIMENTAL PRODUCTION OF THE MENINGO-ENCEPHALITIS OF MUMPS

BY M H GORDON, D M OXF , F R S ,
CONSULTING BACTERIOLOGIST TO ST BARTHOLOMEW'S HOSPITAL

THE interesting case of mumps with symptoms of encephalitis recently described in THE LANCET (March 12th) by Dr Harry Bedingfield has reminded me of an example of this condition which was produced in course of an experimental study of the virus of mumps in 1913 The primary object of the investigation in question was to determine whether any of the well-known nervous complications of mumps could be produced in monkeys *by the* intracerebral injection of a bacteria-free filtrate obtained by passing a gargle from an ordinary uncomplicated case of mumps through the Berkefeld filter The results of this experimental inquiry were described in a special report to the Local Government Board (New Series No 96) published in 1914 Out of some 10 monkeys injected in this way four developed symptoms of nervous *disturbance* and died in from 3–9 days, and sections of the central nervous system showed in all these cases pronounced degenerative changes in the *nerve*-cells Infiltrative lesions, however, were conspicuous by their absence In the case of one of these monkeys that *developed* meningitic symptoms after intracerebral inoculation with a filtered gargle in the manner referred to, however, further sections were made of *the brain after* the report had been issued, and at *one place in* the cortex a spot was found where definite infiltrative evidence of encephalitis was present *The section* showing this lesion was photographed at *the time* by Dr Albert Norman for me, and I was reserving these photographs until I had been able to *carry out a further* study of neurotropic viruses in general, *and of* mumps amongst others The case published by Dr Bedingfield, however, *suggests that this* experimental evidence on the subject of mumps encephalitis may possibly have some interest for clinical observers at the present time, and *therefore I submit* it for what it is worth



A blood-vessel in the cerebral cortex of the monkey, showing perivascular infiltration Magnification × 200

On Jan 18th, 1913, a *M Cynomolgus* monkey *(No 8)* was inoculated intracerebrally with 1 5 c cm and intraperitoneally with 5 c cm of *the filtrate* that had been obtained by passing 100 c cm of saline that had been *gargled* by a patient on the second day of *mumps* through an ordinary Berkefeld filter All the usual precautions necessary *in this* work were taken, and the *filtrate* was *demontrated to be free* of ordinary bacteria. Three days after injection this monkey became quiet, and on the fifth day the symptoms of headache becoming prominent the animal was placed under a general anæsthetic and lumbar punctured. The cerebro-spinal fluid was under increased pressure—some of it spurted out and was lost, but 2–3 c.cm. were collected. This cerebro-spinal fluid was slightly turbid and contained 1500 white cells per cubic millimetre, of which 82 per cent. were lymphocytes, 12 per cent. polymorphonuclears, and 6 per cent. endothelial cells. No bacteria were found in films of it and cultures remained sterile. The monkey's symptoms were much relieved by the lumbar puncture, and though not as lively as usual it was so much better during the next two days that its recovery seemed possible. Later, however, it relapsed, got progressively weaker, and died on the ninth day.

Post-mortem.—No definite naked-eye changes could be made out except for some patches of congestion in the liver and a pronounced degree of fatty change in the cells of the convoluted tubules of the kidney. No pus was found in the central nervous system which appeared to be merely congested. Films of the cerebro-spinal fluid showed a majority of lymphocytes, but no bacteria, and cultures in broth and agar with blood enrichment from the cerebro-spinal fluid and from the heart blood remained sterile. Sections of the cord showed a variable degree—never very pronounced—of infiltration of the pia-arachnoid with lymphocytes. In both cord and cortex there was well-marked hyperæmia, leading occasionally to rupture of the capillaries and small extravasations of blood. A proportion of the nerve-cells both of the cortex and also of the anterior horn cells of the cord showed pronounced degenerative changes.

Discussion

A coloured illustration was attached to the report showing the appearance of the anterior horn cells of the cord in this monkey. A search for perivascular infiltration or for foci of inflammatory cells in the substance of the central nervous system was unsuccessful at the time that the report was made. Subsequently, however, some further sections were made of remaining pieces of the cortex, and at one spot the familiar infiltrative changes of encephalitis were found—namely, perivascular infiltration and also foci of leucocytes here and there in the grey matter. The accompanying microphotograph seems to place the presence of encephalitis beyond reasonable doubt. This particular monkey, therefore, after inoculation with the filtrate of a gargle from an ordinary case of mumps without nervous manifestations developed a condition of acute meningo-encephalitis, to which it succumbed on the ninth day.

Clinical and Laboratory Notes.

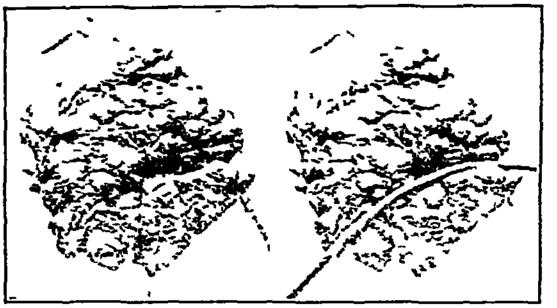
A CASE OF
INJURY TO THE PLACENTA
DURING KRAUSE'S METHOD OF INDUCTION

BY J. HARGREAVES ROBINSON, L.A.H. DUB.,
L.M.R.C.P. IREL.,
HON. SURGEON TO THE ROYAL MATERNITY CHARITY, LONDON;
CAPTAIN, R.A.M.C., ASSISTANT TO SURGEON IN CHARGE,
SURGICAL DIVISION, CAMBRIDGE HOSPITAL, ALDERSHOT

THIS note relates to the second confinement of a woman the subject of pelvic contraction.

Her first child was stillborn after a difficult instrumental delivery, and in the second pregnancy I advised induction, and at the time chosen passed a bougie into the uterus. No obstruction seemed to be encountered as the bougie was introduced, and the only evidence that anything was wrong was a severe hæmorrhage, arterial in colour, ejected forcibly to a distance of about five feet. I withdrew the bougie, ruptured the membranes, and quickly plugged the cervix and vagina with a large and very tight tampon. A binder was immediately applied, and after once encompassing the abdomen, was twisted two or three times to act as a tourniquet, the two ends of the binder being again passed under and over the patient and securely fastened.

The patient was pulseless, and I thought that the bougie had abducted a low-lying placenta. She was returned to the ward and the foot of the bed was raised. Her pulse and colour slowly returned and shortly afterwards the fœtal heart was audible. I therefore concluded that there had been injury to, without complete abruption of, the placenta. Labour pains soon commenced, and the tampon was removed when the head became fixed. The fœtal heart was frequently examined, and preparations were made to meet any conditions that might arise. Thirty-two hours elapsed from the time of the placental hæmorrhage to the birth of a living child which has survived; when the child was born the uterus was more firmly held than is usual, and it was massaged when occasionally it showed a tendency to relax. The cord continued to pulsate for a longer period than is usual.



The placenta, showing the tract of the bougie.

When the placenta was expressed, it showed the track of the bougie, which had almost severed it, as shown in the accompanying photograph. The bougie used was of the type made for the purpose. A large quantity of clots were expressed from the uterus, and when it was empty pituitrin and ergotinin were given by parenchymatous injection. The infant was born in the membranes, completely and symmetrically separated at the margin of the placenta. The mother had a transient syncopal attack when the uterus was empty. The puerperium was normal.

A CASE OF ABDOMINAL PREGNANCY
WITH UNUSUAL FEATURES

BY JOSEPH SILVERSTONE, M.R.C.S. ENG.,
FORMER HOUSE SURGEON, WESTMINSTER HOSPITAL; HOUSE
SURGEON AT THE NORTH STAFFORDSHIRE ROYAL
INFIRMARY, STOKE-ON-TRENT

THE following case appears to be worthy of record.

A woman, aged 32, was admitted to Westminster Hospital on August 13th, 1926, when she had had amenorrhœa for two months. The history was that she had a miscarriage ten days before admission. The doctor then in attendance stated that he had "got it all away," and that he had cleared out the uterus. He showed her the afterbirth. Two days later the patient experienced a pain in her left side, and felt a lump in this region about the size of an egg. The lump increased in size and the pain became worse. A hot water-bottle caused both to disperse.

On admission she had a temperature of 99.2° F., and the pulse-rate was 98. She was very nervous, and complained of pains all over the abdomen, which was very tender. Some slight rigidity was detected in the left iliac region. There was no vaginal discharge and there was a suspicion of a fullness in the left fornix. The urine contained pus, and there was pain on micturition.

The condition settled down, and the patient was quite comfortable for nine days. On August 22nd, however, she felt faint and she began to vomit. She became very pale, sweated profusely, and was very collapsed. The pulse-rate rose to 130, and the pulse was very feeble. There was also a slight blood-stained vaginal discharge. The diagnosis of ruptured ectopic gestation was made, and an operation was performed by Mr. G. T. Mullally, while simultaneously Mr. C. Price Thomas carried out a blood transfusion. The left tube was found to be ruptured in almost the whole of its length, and was removed. No trace of the fœtus was found at the operation.

The patient recovered from the operation and did very wel for a fortnight. Then suddenly she began to vomit, and her pulse-rate rose to 130; it became apparent that she had acute intestinal obstruction.

She was operated upon by Mr. C. Price Thomas on Sept. 6th, and it was found that a loop of small intestine was obstructed by a band extending across the brim of the true pelvis. This was divided, and the bowel freed. The left side of the abdomen was about to be examined when a fœtus, about one and three-quarters of an inch in length shot out from under the left edge of the wound. A small umbilical cord was present, which led down to a definitely formed placenta. The latter was found to be attached to coils of small intestine, descending colon, and omentum. It was separated from its attachments, the attached omentum being removed, and the raw surfaces on the bowel were over-sewn.

The patient did very well and completely recovered.

The sequence of events may be interpreted as follows. The patient had an ectopic tubal gestation from the onset, and the doctor cleared away a decidual cast. When admitted she had a slight hæmorrhage from the Fallopian tube. This was followed, 14 days later, by a complete rupture of the tube, which necessitated operation, the fœtus at this stage being shot out into the general abdominal cavity, where it continued to develop as a secondary abdominal pregnancy.

I am indebted to Mr. G. T. Mullally for his permission to publish this case.

A CASE OF ERYTHEMA NODOSUM FOLLOWING SMALL-POX.

BY WILLIAM L. TULLIS, M.D., D.P.H. ST. AND.,

ASSISTANT MEDICAL OFFICER OF HEALTH, MIDDLESBROUGH.

THE following case presents several features of unusual interest.

The patient, an unvaccinated girl of 6 years, was admitted to Hemlington Hospital on Feb. 1st, 1927, suffering from small-pox. She came from an outlying area and inquiry elicited the fact that the child's eruption had first made itself manifest on Jan. 20th. Six days earlier she had been suffering from malaise, headache, and vague pains. Examination on admission to hospital revealed a rash centrifugal in distribution. The majority of the spots had assumed the form of crusts, amber bead seeds being found especially on the skin of the forearms and ankles.

On Feb. 22nd 10 or 12 swellings, some about the size of a large pea, and others the size of a hazel-nut, made their appearance over the extensor aspect of both legs. Pain and swelling were simultaneous. Some of the nodules were circular, others oval in shape. They were all exquisitely tender on pressure, and involved the subcutaneous tissue as well as the skin. At first bright red in colour they rapidly assumed a dusky hue, and in four days the legs appeared normal. Œdema was not marked.

There was no elevation of temperature, and the pulse and respiration-rate were unaltered. The action of the bowels was normal. Careful examination of the child failed to reveal any evidence of rheumatism. There were no joint pains, no sore-throat, and the heart was normal. The child's general condition appeared good and there was no sign of either tuberculosis or syphilis. The Wassermann reaction was not taken however.

The patient was given salicylate of soda 15 gr. daily, and the lower limbs were protected by cotton-wool. She was confined to bed during her stay in hospital which terminated on March 1st.

This is the first case of erythema nodosum that I have encountered in a series of 1900 cases of small-pox. The chief points of interest are (1) the age of the patient, and (2) the association of the condition with variola.

INDUSTRIAL PSYCHOLOGY.—The annual report of the National Institute for Industrial Psychology was presented recently to the constituency and contains a summary of the active work undertaken, and undertaken to an extent which has justified a considerable increase in the staff of the Institute. The claims of the work and the appeal fund for its support deserve medical endorsement. Expert assistance has been given by the Institute, for example, to the Industrial Fatigue Research Board in the study of problems submitted by the War Office and the Prison Commission, while many children are now examined and advised according to the vocational guidance laid down by the Institute. Inquiries have been made into such varying matters as accidents in mills, the individual differences of workers in their sensibility to colours, the effects of menstruation upon mental and muscular efficiency, and the influence of ultra-violet rays on factory workers. The work of the committees, the character of the investigations in hand, and the arrangements for spreading the activities of the Institute justify the Council in pressing the Appeal Fund upon public attention.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF COMPARATIVE MEDICINE.

AT a meeting of this Section held on March 16th, at which SIR D'ARCY POWER, President of the Section, occupied the chair, Prof. H. MOLLGAARD, of Copenhagen, read a paper on

Chemotherapy with Special Reference to Heavy Metals.

The conception of specific therapy now commonly held was, he said, that it was the same as immuno therapy—in other words, that the therapeutic agent was inherent in the metabolism of the organism itself. No doubt in this respect the immunobiological powers of the organism represented the ideal form of therapy. In many instances—and especially in the case of certain diseases—the action of these powers did not bring about a cure, even when backed up by general medical treatment with vaccines or serums. This failure arose from one of two reasons: either the patient could not produce the agents in sufficient quantity, or their action on the parasite was prevented. In these cases the clinician was faced with the necessity of effecting an alteration in the dominating pathological conditions of the infected organism. This he did either by removing the causes which were preventing the exercise of the natural powers or by concentrating on the destruction of the parasite itself. Since the pioneer work of Ehrlich, scientific chemotherapy had taken account of both these possibilities. The object of research on chemotherapeutic lines was to discover substances which, directly or indirectly, inflicted the greatest possible harm on the parasite with the least injury to the host. It could not be said that any substance had as yet been produced having any remarkable effect on invading micro-organisms without injuring the patient, and our existing knowledge of chemical constitution and pharmacological action was too fragmentary to open up with certainty a way for the preparation of substances fulfilling this requirement. Experimental chemotherapy was therefore at present a series of approximations to the ideal therapy which was carried out by the organism itself, and Prof. Mollgaard thought this was likely to remain the position for some years. This was supported by the fact that the action of any substance now used was not limited strictly to a certain parasite. The effect of even the most approved chemotherapeutical substances seemed to be due to chemical affinities of a more general character, and the term "specific therapy" could be applied only with reservation.

Ehrlich's original conception, Prof. Mollgaard continued, was that the action of chemical substances on the living cell was subject to the existence in such substances of chemical groups or radicals which were susceptible of reaction with other chemical groups in the cell. This conception afforded a basis for current views on metabolic processes.

On the other hand, Ehrlich's conclusion that a parasite could not be killed in the organism by any chemical compound not having a special chemical affinity to its protoplasm was not valid. The substance was not simply introduced to the parasite in a watery solution; it was injected into the very complicated system of the animal body where it underwent chemical changes which might greatly alter its therapeutic effect. Experience seemed to show that chemical compounds might kill parasites in the organism not by reacting with them, but by stimulating the natural powers of immunity. This might prove important for the future development of the method, as it meant that the chemotherapeutist had to deal not only with the chemical reagent and the parasite, but also with the reacting tissue of the infected person C H Browning had happily expressed this when he said that chemotherapeutic substances reacted in coöperation with the tissue

Discussion

SIR **PERCIVAL HARTLEY** said the point which particularly interested him was that though sanocrysin had no effect on certain bacilli, yet if a different strain of those bacilli were used, the drug might have a demonstrable effect It would be of interest to learn more about the differentiation of strains. Did Prof Mollgaard mean differences in the human strain, or such differences as those between human, bovine, and avian types? He had had some experience of treating tuberculosis with sanocrysin, but had lacked the courage to employ large doses at the outset, as he wished to avoid the severe reactions to which they gave rise He thought it possible, however, that when the doses were so graded as to avoid reaction, the results might not be so good as those which apparently followed the larger doses

SIR **LEONARD ROGERS** said he had been reflecting on the parallelism between tuberculosis and leprosy in the matter of chemotherapy, and had come to the conclusion that what Prof Mollgaard had said might explain many of the observations made in treating leprosy. His own work on leprosy in Calcutta strongly supported the view that the reaction of the tissues following the invasion of the infecting organism destroyed a certain number of the micro-organisms, setting free antibodies which produced a gradual immunity. His aim had been to give not a large dose at the commencement to cause a severe reaction, but small intravenous injections of gynocardate of sodium, to induce a series of moderate reactions He related several cases of leprosy in which a surprisingly good result accrued One was that of an Indian patient who had an enormous thickening of the nose, patches the size of the palm of the hand on the back a third of an inch in thickness, and lesions elsewhere He was weak and ill, but at the end of two months after four small injections the lesions commenced to soften and absorb, and at the end of a year the nasal thickening and the patches on the back had disappeared, while in the tissue cut out no bacilli could be found

Prof. **MOLLGAARD**, in reply, said it had been found that the curative influence of sanocrysin depended on the strain, because that was the determining factor in the reaction When working with two different strains it was found that a cure was brought about in something like 75 per cent of cases, commencing with a dose of half a centigramme per kilo of body-weight, and working up to one and a half A sufficient amount of serum had to be employed; but the difficulty was that tuberculous animals were very sensitive to a heterogeneous serum In human beings it was necessary to refrain from large doses, trusting rather to a slow immunisation by successive and gradually increased amounts In cases in which large doses were not tolerated it was found that if quite small doses were given over a period of two or three months the eventual effect was good In the animal experiments carried out it was found that if a dose of two centigrammes per kilo of weight were used a very high percentage of recoveries occurred; if the dosage were reduced to 1 5 the recoveries dropped to about 60 per cent, and to 10 per cent if the dose was one centigramme per kilo Below one centigramme the effect was nil When the disease was severe and was extending rapidly, bigger doses could be employed without risk These larger doses were, however, contra-indicated in cases in which the disease had existed a year, and much fibrous tissue was present The first effect of sanocrysin was greatly to reduce the number of bacilli, but in a few months they would again increase, and thereafter however large the doses given the bacilli would not again be markedly reduced That, he assumed, was because the drug was unable to penetrate the fibrous walls, and the need, therefore was for a more soluble drug which would overcome this disability

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION

A MEETING of this Association was held on Feb 22nd at the British Medical Association House, Miss E **BOLTON**, the President, being in the chair.

Dr **ELIZABETH CASSON** read a paper on

Maternal Instinct in Medicine

She suggested that, while the immense strides made in neurology by the careful observations of facts and their subsequent study were freely acknowledged, the study of instinctive behaviour was considerably neglected in medicine Just as in the spinal cord, medulla, and midbrain, certain tracts are laid down in every individual, so certain definite instinctive responses will occur to set stimuli. Although it is not yet known exactly in what area of the brain these neurotic patterns are prepared yet it seems certain that they are as definitely laid to develop at various stages in the life of the animal as are the rubrospinal and pyramidal tracts A low-grade mental defective has no instinct for obtaining food, no curiosity, and no sense of fear, and has, in consequence, to be cared for as an infant all its life But the normal infant develops all these instinctive reactions at the right time, and as he grows up and during his whole life every activity depends on these same primitive instinctive reactions common to all members of the human race and, to a large extent, to all mammals To the modern psychologist the play of primitive instinctive reactions is as unceasing in every activity as is that of the nerves governing the limbs In every instance of behaviour normal or abnormal primitive instinct is demonstrable, and its recognition and study is necessary for diagnosis and subsequent treatment of any abnormal behaviour W McDougall has pointed out that certain unmistakable specific primary emotions can be observed in animals They are best classified according to the three great ends of the life force—self-preservation, race-preservation, and the herd instincts There are also certain other instinctive reactions with less specific ends There are *anger*, which is aroused when any instinct is thwarted; *curiosity*, with its impulse to investigate anything outside the previous experience of the subject, which forms the basis of all intellectual development and provides the impulse for all research; *joy*, felt when any instinct is gratified, and *grief*, when any instinct has failed in its gratification

The best exposition of parental instinct, said Dr. Casson, was given by W. McDougall, who points out that it is largely ignored by philosophers and psychologists, perhaps because "the instinct is in the main decidedly weaker in men than in women and in some perhaps altogether lacking." Discussing what was meant by the maternal instinct, she pointed out that there were three processes in every reaction occurring in the nervous system—stimulus, appreciation, and either action or a strong impulse to action Appreciation usually showed itself in what was called emotion The stimulus and the resulting action might vary according to the experience and mental make-up of the individual, but the emotion—for example, fear—was specific and unmistakable The emotion specific to the maternal instinct was a yearning to cherish There was unfortunately, no word for it, but it would be heard expressed by an inarticulate sound by the women in a cinema audience when a child suddenly appeared on the screen The mental patient, whether neurotic or psychotic, was, to a physician in the position of a child and provided a stimulus to the maternal instinct This might be the basis of the resentment felt by the doctor at the slightest interference with his or her treatment; who had not met anger in a parent, when someone suggested that she might bring up her child differently.

In suggesting the maternal instinct as a subject for research, there were a few points to be noticed—the age at which it appeared, its physical basis, its abnormalities, its relation to infanticide, its absence in advanced states of dementia Sometimes the return of affection and pity for fellow sufferers or nurses was the first sign of recovery in mental patients It was not easy to provide suitable stimuli for the maternal instinct in a mental hospital Babies were scarce and, except for fellow-patients, there was no one to mother Dogs and cats were the best substitutes Where they could not be persuaded to mother people, patients might be able to express the allied instinct of nest-building and home-making in crafts and other branches of occupational therapy.

An instinct might be abnormal in its unusual strength—for example, in cranks who keep 20 cats or pester their friends for subscriptions to antivivisection societies It might be aroused by an abnormal stimulus or express itself unusually—Mrs Jellaby was a notable example. A patient who has lost a baby, or has been nursing some other relative who has died, might thereafter lavish upon herself all the care and attention that she had been giving to the child. In some cases of the instinct being unsatisfied or being repressed, the patients lost all touch with reality They had babies in phantasy In a mental hospital one might find an old dement gently nursing a pillow. One of Dr Casson's patients, who had been aggressive, noisy, and abusive, had become a different person since she was given a doll

The outcome of Dr Casson's experience was that while it was not waste of time to investigate blood pressure and knee-jerks, it was equally worth while to investigate the primitive instincts If a doctor had been called in to discover early that the instincts of sleep and taking food were deranged in the puerperal cases later investigated so carefully at Broadmoor, then the babies would not have been killed by their insane mothers If investigations were made of the maternal instincts of disgruntled women patients much would be discovered The profession was willing to supply artificial limbs; it might equally well be their job to supply an artificial baby. The maternal instinct was quite as strong, if not stronger, than the mating instinct in most women, and the doctors must be on the look-out for its repression or wrong expression Some women realised their need and knew why they were fretting Others did not know what was wrong with them and did not realise they need the natural outlet of devoted service They were the kind who kept well by doing war-work and collapsed when they were left without it For them a cure must be found—they must be persuaded to adopt a child or guided into teaching, nursing, police, infant welfare work, management of working-class houses, or even into politics By this means a selfish, self-centred, miserable woman might sometimes be transformed into a happy, useful citizen

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH

ON March 8th Dr. HUNTER PATON read a paper on the

Normal Temperature and Pulse

Referring to the common belief that 98 4° F is the normal temperature of the body, he pointed out that this figure only represented the mean of continuous readings during the 24 hours Morning and evening records, as taken clinically, so rarely reached 98 4° in health that such a reading should be looked on with suspicion In his school work he recorded the temperature, night and morning, of any pupil who might possibly have been exposed to infection, and he isolated the child if 98 4° was reached, provided any other symptom of departure from health was detected By this plan he had often segregated cases of the exanthemata before they had given rise to infection, epidemic outbreaks being thus averted

In support of the view that a temperature of 98 4° was rarely recorded in health, Dr. Paton exhibited charts from 61 healthy girls whose morning and evening temperatures had been recorded for 16 days The temperatures had been taken orally with standard thermometers The actual observations made numbered 2169 A reading of 98 4° or upwards was obtained only on 225 occasions Ten of the girls examined did not reach 98 4° once during the 16 days This agreed with his clinical observation that a temperature of 98·4° was commonly an early sign of a disturbance of health The level of temperature in convalescence from illness, usually regarded as subnormal, was the same as that exhibited by these healthy girls Dr Paton's considered opinion was that the normal temperature from the clinical point of view must be regarded as nearer 97 4° than 98 4° The most valuable guide, in deciding whether a borderline temperature was a healthy phenomenon or was due to the invasion of disease, was the pulse If this was increased in rate, or if respiratory arrhythmia was absent, a temperature of 98 4° could not be regarded as physiological A rise of pulse-rate usually accompanied, if it did not precede, the initial rise of temperature, and an increase of rate persisted after the temperature had reached its natural level in convalescence Occasionally, however, a rise of temperature might occur before the pulse-rate was disturbed It was obvious from these facts that the increase of pulse-rate was not due to the pyrexia alone, but that both were due to the presence of toxins The mechanism regulating cardiac action might be more sensitive to some of these toxins than were the processes regulating bodily heat

Reports and Analytical Records.

VULPRO SURGICAL DRESSING.

(MANUFACTURED BY VULTEX PRODUCTS, LTD, GENERAL BUILDINGS, ALDWYCH, LONDON, W C 1)

THIS waterproof surgical dressing is not a fabric but resembles in appearance fine rubber sheeting It is very light, one square yard weighing only 3 oz The dressing is liberally dusted over with boric acid When examined the following results were obtained:—

Loss of weight when dried at 100° C	2 0 per cent.
Soluble in acetone (oils, resins, free sulphur, &c)	5 3 „ „
Ash	3 0 „ „
Heated at 100° C	No change in appearance or elasticity
Boiled with soap and sodium carbonate	
Boiled in water	
Soaked in cold water for 12 hours	
„ „ 1 per cent lysol	
Contact with fæces and urine for 24 hours at blood heat .	Slightly stained

Vulpro is a waterproof material of extraordinary tenacity bearing in mind its low weight per square yard and the absence of any fabric backing It is highly elastic and suffers no permanent distortion when stretched, heated, or washed

---

SOUTH DEVON AND EAST CORNWALL HOSPITAL—During the last five years the work of this institution has increased 30 per cent, and a scheme of enlargement, to cost £40,000, has been prepared The hospital is now seriously inadequate to the needs of the large district it serves It is intended to make provision for paying patients

DRUIDS TINFOIL FUND—The Committee of Control of the Tinfoil (Hospital) Fund of the Ancient Order of Druids report that 94¼ tons of tinfoil were collected by its agency in 1926, in 1925 the total was 72 tons The committee complain of the "unfair competition" of other organisations which are now collecting tinfoil, not for the hospitals but for their own purposes The year's sales realised £2251, making a total since the fund began in 1922 of £8895 Fourteen beds in various hospitals have been endowed with the money, four more are now to be endowed

Reviews and Notices of Books.

THE LIFE AND WORK OF SIR PATRICK MANSON.

By PHILIP H MANSON-BAHR, M D, F R C P, and Lieut -Colonel A. ALCOCK, C I E, F R S London Cassell and Co, Ltd 1927 Pp 273 16s.

ON March 15th Mr Neville Chamberlain unveiled a tablet in the Albert Dock Hospital to the memory of Sir Patrick Manson who taught and practised there through the knowledge which he had gained with his own hands in a long struggle with the unfriendly tropics By a happy chance there appears, almost at the same moment a second monument to that great fighter, and one which will proclaim him widely and cause many men to think on what manner of man he was and some to follow where he led Dr Manson-Bahr and Colonel Alcock show, in this account of Manson, some of the patience for which their hero himself was so conspicuous, and have traced his life in great detail from the growth of his passion for medicine to his retirement from active life, and his death from heart failure in 1922 at the age of 77 His early struggles in Formosa and Amoy are detailed with his long, arduous and fruitful career of research and practice, his splendid creative work for the profession and public in Hong-Kong is described, and so we reach the crown of his life, the foundation of the London School of Tropical Medicine

His discoveries in tropical pathology are familiar to all and the volume contains a full list of the mass of valuable literature which he published throughout his life It is, however, for a portrait of the man himself that most readers will turn to this biography, and they will not be disappointed A Scotsman of the sturdy Aberdeen breed, with a passion for knowledge and an even stronger one for friendship and service, he was often crippled by gout but remained untiring at his work and as far as possible at his play —for he was a dead shot and a keen fisherman We get a picture of Patrick Manson from his son-in-law as a lovable no less than an admirable man The portrait, however, is drawn from the man as he was when, ripened by well-spent years, he returned to London About the Manson of the lonely Chinese hospitals and the improvised laboratories we can only guess, for few who knew him in those days still survive All we gather from his diary and letters is a glimpse of one who worked early and late under the most trying conditions of climate and the severest handicaps imposed by lack of proper equipment and by native prejudice, at the twin vocations of research and healing We see a man to whom nothing was too much trouble to do supremely well, to whom every discrepancy was a challenge to further exploration, and whom every form of suffering urged to spare no efforts for its relief. Manson's versatility stands most conspicuously out in a history of his life His researches cover parasites and bacteria of most diverse species, he was a highly gifted surgeon and a very efficient medical officer of health, and was trusted implicitly as an obstetrician by even the exigent Chinese. He was a fine publicist and a capable organiser, and founded the Hong-Kong Medical Society, the Hong-Kong Medical College, and the Tropical Section at the the annual meeting of the British Medical Association He was a voluminous and admirable writer. In his recreation, apart from his fishing and shooting, he had a professional knowledge of geology and was a first-class naturalist Very few men combine as he did the opposite qualities of imagination and application; he was content alike with solitude and publicity, and while keenly logical had a warm deep humanity

The book should be read as long as our tropical dependencies rely on the solution of disease problems for their prosperity in other words the Father of Tropical Medicine will always be kept in grateful memory.

MICROSCOPY OF THE FÆCES

Coprologie Microscopique. By M. LANGERON, Chef de Laboratoire a la Faculté de Médecine de Paris, and M RONDEAU DU NOYER, Preparateur a la Faculté de Pharmacie de Paris Paris: Masson et Cie 1926 Pp 132. 2s.

THIS little volume on a very important subject—the microscopy of the fæces—has been framed on modest lines. It claims to be, and, in fact is, essentially practical Within 132 pages the authors have succeeded in summarising the essentials of this subject. The descriptions of the various objects, parasitic and otherwise, which are found in the fæces are clear and accurate The text is illustrated with 129 text-figures in black and white, and a useful feature is the micromillimetre scale which accompanies them Unfortunately, these illustrations, especially of the protozoa, are not up to the usual text-book standard The greater number could, with advantage, be redrawn for a future edition

INDEX AND HANDBOOK OF X RAY THERAPY.

By Dr ROBERT LENK, Privat-dozent of Medical Radiology, University of Vienna Translated by T I CANDY, M B, D M R E, Hon Radiologist Royal Gwent Hospital, Newport London: Oxford University Press 1926 Pp. 121 6s 6d.

IT is now six years since Dr Lenk, of Vienna, published this little book, which was quickly translated into several languages We now have to thank Dr Candy for an excellent English version The book is primarily meant for the general practitioner, and by means of a formula describes suitable X ray dosage and filtration for a large number of pathological conditions These are arranged in alphabetical order convenient for reference Most X ray workers in time evolve their own technique, but as a working basis for those with little experience, nothing could be better than this handbook, backed up as it is by the mature experience of the Vienna school of radiotherapeutics This book is well published and well translated, and can be confidently recommended to all radiologists

THE PRINCIPLES OF PATHOLOGY.

By C POWELL WHITE, Manchester University Press London Longmans, Green and Co 1927. Pp. 279 15s

SOME people think that pathology is nothing more than a useful adjunct to medicine and surgery; to them a " pathologist " is one who helps in diagnosis during life by carrying out laboratory procedures, which are now of bewildering variety, and by verifying the cause of death at autopsy A minority have, however, urged from time to time that pathology is a biological science which can stand on its own feet, and has principles of its own to work out What these are Dr Powell White has sought to state in an interesting and refreshing book; it will, we imagine, come as rather a surprise to a good many pathologists that it is possible to discuss the subject in such terms as he uses. His main thesis is that the proper subject matter of pathology is the study of adaptation to adverse conditions, whether the adaptation be one of organism organ, tissue, or cell. he goes, indeed, further and is prepared to recognise the existence of living units ('biomeres ") of a lower order than cells He derives pathological processes from the processes of general biology and rightly suggests that biologists might get as much help from pathology as pathologists may from biology. The fundamental point from which pathology starts is morbid anatomy, because it is quite characteristic that each living thing has a definite morphological organised structure, and the ultimate basis of life is morphological rather than chemical Pathological processes are divided into consecutive (the direct results of injury), adaptive (the attempt to correct the injury), and autonomous (arising within the organism and proceeding along a defined course—e g, senile changes) Such are examples of the fresh way in which he orders familiar facts We know of no recent book in English which a senior student might read with greater profit; it is not one to begin with, for it presupposes a tolerable acquaintance with the ordinary data of pathology, and seeks to describe the relationships of pathological processes rather than their details It is particularly valuable because it is provocative enough to compel the reader to think at least a little for himself The day is pretty far distant when anyone will write a satisfying philosophy of pathology Dr Powell White has certainly not succeeded in his present attempt But he has done a very real service to the science if he has succeeded, as we think he has, in showing that such a philosophy is possible and in getting people to think along the lines which will help its realisation.

BACTERIOLOGICAL ATLAS

By RICHARD MUIR, Demonstrator of Pathological and Bacteriological Methods in the University of Edinburgh Edinburgh: E and S. Livingstone 1927 Pp 134. 15*s*

THE idea of the Atlas, we are told, is to convey a picture of the various pathogenic micro-organisms as seen with the microscope This idea Mr Muir, whose skilful portrayal of microscopical preparations has long been familiar to medical students and practitioners, has successfully realised. The question as to how far it is desirable to insist upon the morphological characters of bacteria, which an atlas connotes, is not relevant, for serious students will soon learn the importance of other methods of distinguishing between organisms The 60 beautiful plates here reproduced are up to Mr Muir's usual high standard The only criticism we would level against the book is that the magnification at which the pictures are produced is considerably greater than is usually attained to by the student, and hence to his mind the organisms are shown in an idealised form

STRAY LEAVES FROM A PHYSICIAN'S PORTFOLIO.

By SIR JAMES CRICHTON-BROWNE, M D, LL D, F.R S London Hodder and Stoughton Pp 351 12*s* 6*d*

SIR James Crichton-Browne has published here an olla-podrida of lectures, articles, and literary studies which have appeared from time to time in magazines and reviews and makes from them an entertaining and instructive volume The first and most serious paper is a reprint of the Cavendish Lecture delivered before the West London Medico-Chronological (sic) Society on June 30th, 1895; this dealt with the conditions known as "Dreamy Mental States," which vary from the well-known "I have been here before" feeling to the state of mental exaltation described by Tennyson and others in which the subjects seem to themselves to "touch the skirts of immensity and mystery" Another paper deals with that unhappy personality Branwell Bronte, who in the author's opinion was not so bad as he has been made out to be The paper on "Claret in Scotland" is admirable reading at this juncture, especially when it is prophesied that the tax on spirits may be lowered and that on foreign wines be increased We commend the following remark of Sir James Crichton-Browne to the authorities—"the substitution of whiskey for ale and claret as the popular stimulant in Scotland was a great national misfortune which still affects the country," and the author goes on to give cogent reasons for his statement Other papers deal with such diverse subjects as Light and Sanitation, Thomas Young Poisons and Poisoning, and as a whole the book makes excellent matter for reading at odd times

MICROBE HUNTERS

By PAUL DE KRUIF London Jonathan Cape 1927. Pp 389. 12*s* 6*d*

THE American edition of this book which appeared last year contained allusions to which strong exception was taken by some of our readers (THE LANCET, 1926, ii, 729) The English edition which has just been issued loses little by the omission of certain chapters containing references to living workers, for the book is no ordered chronicle of bacteriological progress, but a flashlight turned upon some of the peaks in the irregular chain of men whose height of achievement is outstanding That such beams sometimes give a distorted image—manifest in photographs of public celebrations and on every man's passport—does not prevent Dr de Kruif's book of impressions, at any rate in the form in which it has reached us, from being vivid and stimulating He outlines in turn Antony Leeuwenhoek, Lazzaro Spallanzani, Louis Pasteur, Robert Koch, Emile Roux, Emil August Behring, Elie Metchnikoff, Theobald Smith, Walter Reed, and Paul Ehrlich, these sketches show an intimate knowledge of the exhilaration and reaction which in different proportions make up the life of every research worker. Dr de Kruif's style is exuberant without affectation, and though it may jar some of his readers it will appeal to others He is sometimes unrestrained and occasionally rather theatrical, but he does make us catch the frenzy, savour the bitterness, and share the triumphs of each investigator in turn Koch alone does not come alive for the reader, perhaps because the Teutonic reserve and thoroughness does not lend itself to this sort of impressionist study Certain phrases lose their force by repetition—for example, too many of these pioneers are said to "sniff" round their objectives Dr de Kruif is so far steeped in the lives as well as in the works of the microbe hunters whose fortunes he follows that we find ourselves zealous partizans, fearing that the next page will bring news of discomfiture or discredit to those whose adventures no investigator, however humble, can help identifying with his own All who aspire to enlist among the irregular legions who fight for knowledge of any of the biological sciences will enjoy this book.

JOURNALS

INDIAN JOURNAL OF MEDICAL RESEARCH Vol XIV, No 3 January, 1927—In this number P J Barraud continues in four lengthy articles his revision of the Culicine Mosquitoes of India, Parts XIX—XXII, this is a painstaking work of purely entomological interest—H E Shortt, in collaboration with several fellow workers, contributes a series of five papers dealing with various aspects of the leishmania problem, and together with P J Barraud and A C Craighead describes abortive attempts to transmit the infection through *Phlebotomus argentipes* to laboratory animals—R McCarrison has four original papers dealing with his specialty, the effect of various cereals and manganese on growth, and the further detailed history of goitre in the Military School, Sanawar, Punjab—R B Lloyd, E Muir, and G C Mitra have investigated the influence of syphilis on leprosy as indicated by the Wassermann reaction, whilst N H Fairley publishes for the first time his remarkable observations on the spontaneous cure of bilharziasis (*S spindalis*) in monkeys—Asa C. Chandler contributes a further series of three papers on the prevalence of hookworm and other helminthic infections in India, E O Hodgson, A C Vardon, and Zorawar Singh describe, in a preliminary note, the blood sedimentation test as a quick and simple means of differentiation of malaria from kala-azar, enteric, and other fevers

HEALTH WEEK—This year's Health Week is being arranged for Oct 2nd to 8th Appeals for the coöperation of local authorities have been issued by the responsible committee, of which Prof Bostock Hill is chairman, from 90, Buckingham Palace-road, London, S W 1

THE LANCET.

LONDON SATURDAY, MARCH 26, 1927

LODGING FOR THE NIGHT.

THERE are still a great many homeless people London Some of them are incapable of domestic fe, some are too frail or too unskilful to earn the nt of a room, others are separated from their iends or families, either by fault or misfortune ll these have to find a roof at night and their choice, they have little money, lies between the Poor-law sual ward, the free "shelter," the unlicensed doss- ouse, and the common lodging-house The first ternative is universally disliked It smacks of rison, for it means solitary confinement by night d detention by day, its welcome is intended to revent return, and even if applicants are no longer t at oakum-picking their tasks are often just as seless and therefore as humiliating The free shelters e of variable quality, they are under no central thority and comprise alike the excellent establish- ents of the Salvation Army and a series of philan- ropic institutions many of which are out of date d insanitary Shrinking from all kinds of institu- onal charity, some of the poorest people find cover the unlicensed doss-houses which still exist in e East and South of London A bed in a doss- use costs 3*d* or 4*d* per night and the standard comfort is necessarily low since they are run profit The same objection applies to many of e establishments licensed as common lodging- uses by the London County Council, which form e fourth alternative resting-place They number 5, having accommodation for 14,855 men, 1944 men, and 246 married couples, and they may divided into three groups, according to the tariff Group I (*5d* to *7d* per night) there are only l beds for women These are always fully occupied, d are wholly provided by philanthropic agencies, e reason being that women are relatively expensive dgers, and with the lower rents leave no margin r profit under the Council's conditions of inspection Group II (8*d* to 10*d*) there are 882 women's ds and about 10,500 for men, 3000 of them owned ther by the London County Council or by philan- ropic agencies Lastly, in Group III (from 11*d* pwards) the female accommodation is privately ned, whilst most of the male beds are kept by the uncil. Taking all three groups together the pro- rtion of beds usually occupied is 85 per cent for men d 92 per cent for women The total accommodation ailable has decreased from 29,574 beds in 1894 17,045 at the present time, this being attributable a steady decline in the numbers of the common lging-house class During the same period the uncil has secured much greater cleanliness of uses and equipment, and the shocking conditions scribed about the middle of last century have no rallel to day

The above figures are taken from a report[1] by F N KAY MENZIES, which forms an interesting ly to criticisms of the Council's regulation of ing-houses In a recent book[2] Mrs CECIL CHESTERTON gives an account of her own adventures in these institutions

"There is," she says, "a deplorable lack of proper *accommodation for the itinerant London outcast.* Be she matchseller or prostitute, she should have the opportunity of getting a decent bed on payment of a fixed sum Outside the Salvation Army shelters the standard of cleanliness is variable Among the public lodging-houses, run for individual profit, it is extremely low, and in some of these places the beds are stained, the blankets dirty, the washing accommodation of the most rudimentary kind, and this, it is somewhat disconcerting to find, in houses licensed by the London County Council and under its inspection"

Describing the fate of women left without references or friends she attributes their deterioration, inter alia, to the conditions found in common lodging-houses Forced to sleep in a dirty bed, without facilities for keeping body or clothing clean, the homeless woman inevitably loses self-respect, sometimes ven the public wash-house refuses her admission Regarded *as worthless, she soon becomes so, and for want* of a few days' decent lodging and a helping hand acquires the mental and physical stigmata of the outcast Not only, says Mrs CHESTERTON, is the accommodation for women often degrading, but it is also insufficient Although the County Council have established admirable lodging-houses for men they refuse, she says, to do the same for women, because a fair proportion of the lodgers in licensed houses are prostitutes, and the Council are "terrified to be associated in the work of providing beds for prostitutes lest they should be accused of countenancing a loose method of life" To a widespread prejudice against destitute women Mrs CHESTERTON ascribes the shortage and low standard of accommodation provided for them And this failure of accommodation she blames for the progressive degradation of many useful members of society As a remedy she would, first, erect shelters—free or at nominal rents—to which all in need should be admitted without any inquisition, secondly, set up hostels for manual workers, and, thirdly, provide comfortable lodging-houses for women—similar to those for men—at an economic rent of 10*d* to 1*s* 4*d* Thanks to Mrs CHESTERTON's efforts a well-equipped lodging for 45 women is to be opened this year in Bloomsbury by Cecil Houses (Incorporated)

Dr MENZIES sees the situation differently Even the present reduced accommodation, he considers, is more than adequate, and of temporary shelters there are plenty The cheaper common lodging-houses are almost always full, but that is because they are kept at a financial loss by philanthropic bodies, and advantage is naturally taken of their alms Many of the inmates could well afford to pay for beds elsewhere at higher prices, whilst others should properly be in Poor-law institutions It is almost unanimously agreed, he remarks, that the amount of cheap lodging-house accommodation ought not to be increased, as this step would simply lessen the demand for beds at a higher rental Attempts have been made in the past, he points out, to provide really good lodgings for working women and girls, but they have almost always come to grief The lodgers either resented "ordinary disciplinary regulations" or else made no effort to take advantage of the amenities offered "These are facts of practical experience," says Dr MENZIES, "which should be borne in mind by those who think that men have been better and more considerately treated than women," and it is certainly to be hoped that a happier fate will attend the new Cecil House, and an establishment of similar purpose which is being put up by the Church Army Together these institutions will increase the total accommodation for women by 10 per cent It is right however, to remember that it is not the Council's object to encourage the hostel or lodging-house habit, but rather to hasten its disappearance In the meantime, though the accommodation appears æsthetically repellant, it is doubtful, says Dr Menzies, whether anywhere among the poorer classes there can be found a standard of house cleanliness at all comparable to that of the licensed lodgings Admittedly, they are far from perfect Washing arrangements are often inconvenient and in 30 of the 37 houses for women there are no bathrooms But these conditions are parallel to those in working-class homes The price paid by casuals is too small to allow provision of a fresh pair of sheets for each newcomer, those offered must be "clean but not necessarily fresh" And in the women's lodgings equipment is especially difficult because bits of bed linen are frequently abstracted and because sheets are easily soiled—facts which partly explain the lower standard of the accommodation provided Clearly, the present state of affairs need give rise to no complacency Much has still to be done to ensure that men and women have quarters as good as their money will buy, and a reform in spirit as well as in regulation is needed if the Poor law is to lose its degrading effect The lot of the destitute may be improved, however, without wholesale establishment of free shelters or lodgings at a nominal rent Such philanthropy would create its own problems, and would be mistaken, since the function of charity should rather be to meet emergencies than to sustain the major burdens of society

BIOLOGICAL RELATIONS OF OPTICAL ISOMERS

Probably no one could have foreseen that Pasteur's discovery in 1848 of the association between the asymmetry of the crystals of tartaric acid and their optical rotation when in solution was to lead to a clearer recognition of the intimate nature of the response of tissues to drugs Yet such is the case, and the story of the intervening steps has been told in a manner at once clear and full of interest in a volume[1] which has recently appeared from the pen of the late Prof A R Cushny The book has a significance apart from that due to its value as a record of a line of work to which he contributed so much, in that it forms the last publication of one of the greatest investigators among the modern school of physiologists Le Bel and van't Hoff showed in 1874 that optical isomerism exists in those compounds which possess an asymmetric carbon atom in their molecular configuration When such compounds, however, are built up in the laboratory without use being made in their synthesis of any substance which already shows optical rotation, the resultant compounds are invariably racemic The resolution of a racemic mixture into its optically active components demands the presence of some compound which is itself optically active This law is illustrated in Pasteur's second method of separating the isomers of tartaric acid, he found cinchonidine l-tartrate much less soluble than the d-tartrate, and so by this means was able to resolve the originally racemic mixture A vast field for speculation is thus opened up as to the origin of the first compound possessing optical activity, and attention is directed by Prof Cushny to the possibility that temporary molecular rearrangements may be brought about by some external source of energy, a suggestion brought forward by van't Hoff and studied by Erlenmeyer when working on the asparagins A third method of separating optical isomers from a racemic mixture is also to be attributed to the genius of Pasteur. It was found by him that moulds and yeasts attacked ammonium d-tartrate much more actively than its lævorotatory isomer The enzymes, however, cannot be classified into those destructive to lævorotatory and those destructive to dextrorotatory bodies; nor do different enzymes select the same isomers from a given racemic mixture Further, some enzymes act on each optical isomer of a given pair to the same degree, others act on both but with unequal potency, others yet again act only on the one isomer "It is impossible," says Prof Cushny, "to state a priori which isomer will prove the more susceptible"

These in vitro observations have their counterpart in experiments in which the fate of isomeric substances administered to animals is determined. Since the metabolic changes undergone by such substances in the body must be considered as due to enzyme action, it is not surprising that we usually find the dextrorotatory and lævorotatory isomers attacked unequally, and that occasionally tissues show no preference for the one or the other For example, d- and l-tartrates are equally oxidised in the tissues, whilst the optical isomers of such closely related bodies as the malates show a distinct difference in their susceptibility to breakdown by the tissues, the natural lævo- being much more readily attacked than the artificial dextro- form The first definite experimental evidence that a difference may exist in the response of a tissue to the optical isomers of a given compound was brought forward by Cushny working on the hyoscyamines He discovered the interesting fact that l-hyoscyamine was about twice as potent in its action on the nerve endings of the autonomic nervous system as d-l-hyoscyamine (atropine), the conclusion drawn from this observation being that d-hyoscyamine was practically devoid of action at these sites This conclusion was shown experimentally to be valid Analogous results have since been obtained with other isomeric substances such as the hyoscines, nicotines and epinephrins In some cases each isomer exerts a potency equally to that of its image, in others both are effective but in unequal degree, and yet in other cases one is effective and the other completely inactive

We find, then, in the study of the pharmacological reactions of isomeric substances a state of affairs which is closely akin to that existing between optical isomers and alkaloidal reagents on the one hand, and between optical isomers and enzymes on the other. Cushny points out that there can be very little doubt that fundamentally we are dealing with similar chemical reactions in these three cases that l-hyoscyamine has a much greater action on the autonomic nerve endings than d-hyoscyamine for precisely the same reason that l-tartrate is more easily precipitated by cinchonidine and less readily oxidised by penicillium than d-tartrate, "that is, because in the tissues, as in the test-tube, the isomers form compounds with some optically active substance, and these compounds are no longer mirror images and no longer identical in their physical characteristics" There are, of course, other factors besides the optical rotation of a pharmacological substance which must be taken into account in attempting to correlate the physical and chemical constitution of drugs with their action on the tissues G Barger and H. H Dale found that the action of sympathomimetic amines was in some cases greatly reinforced by substituting OH for H in the molecule, and thus rendering one carbon atom asymmetrical The resultant increase in activity was naturally attributed to the asymmetry, but Cushny has recently shown that in the tropeines the presence of the hydroxyl group rather than the asymmetric carbon atom per se is the activating factor For example, it was found that hydratropyl tropeine. which differs from atropine merely in that the CH_2OH group of atropine is replaced by CH_3 has only about one two-hundredth the activity of atropine in arresting salivary secretion We see, therefore, how three factors come into play in determining the relative efficacy of a chemical compound in producing a given physiological response First there is the necessity for a certain molecular configuration—phenacetyl tropeine has a slight atropine-like action—to the compound , secondly, the presence of alcoholic hydroxyl in the side-chain of the acid augments the activity to a very large degree , and thirdly, an asymmetric carbon atom, by conferring optical rotation on the compound, is responsible for the potential difference in pharmacological activity between the optical isomers of that compound The similarity which a given optical isomer exhibits in its reactions with an optically active alkaloid, with an enzyme, and with the particular tissue on which the isomer concerned is said to exert a specific pharmacological action, points clearly to the presence in the tissue acted upon, of a chemical grouping similar to that found in the alkaloid and enzyme As Prof Cushny put it, “ Pharmacological investigation may then be regarded as a method of applying a qualitative test for the presence of certain chemical groupings in living matter and joins other biochemical methods in that object ” It is this valuable method of in vivo biochemical analysis which he has placed in our hands Such specific effects as those resulting from the action of the digitalis group on the heart muscle and cardioinhibitory centre, of morphine on the respiratory centre, pain path, and gut, and of atropine on the parasympathetic nerve-endings and central nervous system, thus receive a rational explanation But Prof Cushny was careful to point out that pharmacological methods alone can do little more at this stage of knowledge than to provide further examples of such reactions Their analysis must await a clearer insight into the fundamental nature of the interactions between optical isomers and alkaloidal reagents on the one hand, and between enzyme and substrate on the other, and these can only be furnished by the experimental methods of physics and chemistry

POST-MORTEMS AND INQUESTS.

When a consultant after a careful examination, admits that he has failed to make a diagnosis, the patient is apt to distrust his skill or his thoroughness, and to go elsewhere The next man approached realising that a definite conclusion is expected of him. is sometimes tempted to dogmatise on mighty little evidence His guess may be a lucky one—in which case he derives much credit and still deserves it, since medical diagnosis cannot be an act of rigid deduction In certain branches of medicine, however, mere presumptive evidence is hardly allowable however much satisfaction it may give to the parties concerned These reflections arise from the report of a recent case where a coroner dissatisfied with the negative results of an autopsy performed by a professor of pathology at a great London hospital called for another post-mortem by a pathologist known to him but not attached to any teaching hospital The second autopsy was duly performed and although no further light was thrown on the case by the pathological changes found. the cause of death was pronounced to be angina pectoris on grounds of clinical history The interesting point is that the report of the first post-mortem examination was if anything fuller and more helpful than that of the second There seems to have been nothing in the naked-eye examination of the organs to show the cause of death There is no record that any histological examination of the tissues was made on either occasion

The last thing we would desire would be to damp a coroner’s enthusiasm for post-mortem examinations. These should be held much more frequently than they are especially in private practice, but the ordinary coroner’s post-mortem is often useless because (*a*) it is done too late—by the time the formalities have been gone through post-mortem decomposition is well advanced ; (*b*) no microscopic or bacteriological examination of the organs is made In a large number of cases the naked-eye examination alone is inadequate ; the true condition can only be found on microscopic examination Moreover, it is a mistake to assume that a post-mortem even with microscopy, will invariably clear up the mystery of the cause of any death It is often enough impossible to say why a patient died A patient may reveal chronic lesions which must have interfered considerably with his physiology, yet he must have carried on with the disabilities for a considerable time A milder degree of disability on the other hand, would have proved fatal to another individual. The interesting speculation is often not why did the patient die ? but why did he not die months or years before ? It is *obvious that* the clinical history is of the first importance On clinical evidence alone the cause of death can often be given with a great degree of probability but the post-mortem may be necessary to exclude other possibilities For example a patient suffers from acute gastro-enteritis and dies In all probability he dies from acute food poisoning and a certificate may justifiably be given A superficial naked-eye post-mortem may give no more information than that the patient had acute inflammation of the stomach and intestine and death will be put down to toxæmia or syncope But a post-mortem may be advisable or necessary to exclude for example, arsenic, or to determine the nature of the food poison when an extensive bacteriological and chemical analysis will be necessary In short a post-mortem may be necessary to exclude other than apparent causes of death but it must be complete.

A combination of clinical and pathological evidence will usually clear up any case, but the danger in legal circles lies in placing too much importance on pathological evidence It is almost true to say that the better the pathologist the worse the witness . In the witness-box it is no good offering suggestions or tentative opinions To the legal mind facts are facts, and science is science and it is possible to be certain of anything under the sun The scientific pathologist will rarely say more than that his findings did or did not square with the clinical evidence. or that he found certain *conditions* which might well be incompatible with satisfactory physiological functioning of vital organs It is one thing to discover pathological lesions and quite another to determine how far these lesions are of vital importance ; even an expert can only express an *opinion* and in 99 cases out of a hundred the opinion may be correct But sooner or later, he is asked. not whether a person died of such and such a lesion. but whether he was killed by it Then he comes up against the conflict between scientific doubt and legal necessity For the credit of medicine scientific fallibility—in the biological sciences especially—should be properly recognised and medical witnesses will always be in a dilemma till this is done

Annotations.

"Ne quid nimis"

THE HEALTH OF THE COAL-MINER

We have already given some account[1] of the Industrial Health Education Society and its activities in teaching employees to defend themselves against occupational hazards Not the least useful among its publications are the pamphlets dealing with conditions of life in different industries, and of especial interest at the present time is one entitled, "The Coal-Miner," by Prof E L Collis, whose experience in the preventive medicine of mining and whose efforts to promote the welfare of miners make him a recognised authority The long series of stoppages in the industry is, he thinks, the price of neglecting the miner's needs Lack of provision for details of comfort and efficiency leads directly to a high mortality from the four main causes of death—phthisis, pneumonia, bronchitis, and accidents Mortality-rates are alike the measure of this neglect and of the dissatisfaction it causes, thus the strike ballots taken on the various coalfields, which indicate numerically the miners' collective dissatisfaction with the conditions in the industry, show an order closely parallel with that of the mortality records Nor does it seem that we have profited much by bitter experience Prof Collis considers that in one direction alone—that of social welfare—is any considerable attempt being made to improve the miner's life, and he points out clearly where each set of conditions is at fault and how they may be bettered Hot food supplied from the pit-head and drinking-water piped to the workings, as it already is in the United States, are needed, he says, to ensure better health and efficiency, for the amount of body-fluid lost at work underground may be anything from one to two pints an hour In America, where miners are supplied with electric cap lamps, nystagmus is rare, in England it is common, and the large bulk of the patients are users of safety-lamps Compensation claims for this disease out-number claims for all other industrial diseases taken together, so there is a strong pecuniary as well as a sentimental reason why every effort should be made to improve underground illumination One of the most urgent needs, however, is the provision of baths at the pit-head The miner at the end of his shift is black with coal-dust, is tired, and is cold and wet with perspiration No other worker needs a bath and a change so badly before travelling home He has to risk catching a cold that may lead to pneumonia and to endure the ostracism of fellow-passengers in public vehicles as the ordinary end to every working day Even harder, perhaps, is the burden on his wife, she has to prepare the bath, which is taken on the hearth in the living-room, and has to put away the bathing utensils, scrub the floor and, worst of all, to clean and dry her husband's clothes, which are covered with mud and coal-dust, and which soil all they touch Many children are killed through falling into the hot water prepared for their fathers, one coroner says that he holds more inquests on children dead from scalds and burns than he does on miners who die from accident Nearly every country but this has laws enforcing the provision of pit-head baths, but British owners, as a whole, still cannot see their productive value, and the men—naturally a conservative class—are only half-hearted in their demands for them Unfortunately there is also opposition from the wives, and some employers complain that this is the deciding factor Once clean, the wife argues, my husband can go off to the public-house and never come home till nightfall, I would rather make him come home for his bath and retain some hold over his leisure Dirt and inconvenience, however, are poor props to domestic life, and Prof Collis, for his part, considers that provision of baths would probably be a more important reform than any other single measure, besides enormously reducing the incidence of respiratory disease and of the various skin troubles peculiar to miners, they would, he thinks, remove a great deal of the existing inducement to convivial drinking, and thus increase the miner's self-respect Their introduction, long overdue, together with that of hot food, adequate drinking-water, and improved illumination, would lead to an enormous gain in efficiency and health and thus prevent many accidents, 80 per cent of which are due to personal carelessness, often the result of some degree of ill-health They would make happier homes and, by relieving the house-wife of much labour, would reduce the infant mortality These measures would not be a high price to pay for the removal of a large amount of industrial discontent It is to be hoped that we shall not long continue to lag behind our neighbours in applying to this most important industry our great national gift for hygiene and preventive medicine

OBSTETRIC LESIONS OF THE SPINAL CORD

Birth trauma affecting the central nervous system has received increasing attention during the last few years On this subject the obstetrician, the pædiatrist, and the neurologist find common ground, and the concerted effort which they have made to elucidate its problems may be seen in the writings of Eardley Holland, O. Schwartz, H C Cameron, W J Adie, and others This research and controversy has been almost confined to cerebral injury, and whilst current medical opinion attributes to this cause many cases of spastic diplegia which would, some years ago, have been regarded as prenatal in origin, curiously little interest has been taken in the possibility that the spinal cord commonly receives similar injuries The work now recorded[1] by Dr Bronson Crothers and Dr Marian Putnam will have the effect of focusing attention on this aspect of birth trauma They describe 28 cases of infants and children exhibiting lesions of the spinal cord, in which the evidence of trauma during delivery was in most cases unequivocal, and in all except one extremely convincing The injury almost invariably appeared to follow traction during delivery. The series is fully described and illustrated by photographs and diagrams interpreting the physical signs The conventional methods of neurological examination are hard to apply to small children and were largely abandoned in favour of objective observation of the child's behaviour, whilst interpretation of disordered function was in general based on the work of Sir H Head and G Riddoch on the action of the isolated cord The clinical observations are not easily summarised, but the 28 cases fall roughly into two classes The greater number (17 of those in which the method of delivery was known) were breech deliveries, and version and extraction had been performed in a large proportion of these One of the breech cases showed bilateral flaccid brachial paralysis with damage of the sympathetic but the great majority gave signs of diffuse damage to the thoracic cord with partial or complete isolation of the lumbar cord, in a certain number lively reflex activity was observed in the parts below the transection

The second type of lesion was found in cases of head presentation delivered by forceps In five out of eight of these the signs pointed to avulsion of brachial nerve-roots with damage to the adjacent part of the cord It is suggested that one of them may have been the result of resuscitation by swinging It is significant that in the only case in which labour was known to be normal the evidence of cord injury was not conclusive, the signs being compatible with a lesion of the superior longitudinal sinus, as suggested by Adie A remarkably small number of these cases were fatal, but in two autopsies the brain was found to be normal, whereas there was extensive hæmorrhage, or crushing, of the thoracic cord The clinical account of the cases, and the able discussion accompanying them, raises several questions of speculative interest to the neurologist Of the children having residual paraplegia, conventionally classed as cerebral diplegia, in whom mental development was normal, may not a percentage have been suffering from spinal injury below the cervical enlargement? The extent to which afferent functions persist, or return, in the damaged cord appears to differ in the infant and in the adult; in one child two months old micturition was elicited by nocuous stimulation of a flaccid limb Observation of further material of this kind should yield evidence on the action of isolated spinal elements and thus supplement information gained during the war From the practical standpoint Dr Crothers and Dr Putnam lay special stress on the apparent liability of traction during delivery to cause spinal damage, and the importance of determining the extent to which traction can or should be avoided They recognise that this question must be answered by obstetricians and invite their cooperation in deciding the attitude which should be adopted on the grounds that "the striking contrast between the apparent incidence of injury and the almost total ignoring of the subject by writers of obstetrical textbooks justifies us in suggesting that a definite shift of emphasis is desirable"

SICKNESS AND DISABLEMENT BENEFITS

AN important section of Sir Alfred Watson's address on National Health Insurance delivered before the Royal Statistical Society on March 15th, dealt with the claims for sickness and disablement benefits Among both men and women the claims for sickness benefit fell greatly during the war years; this was particularly the case in regard to women who in 1916–17 drew less than two-thirds of the sum drawn by them in 1913–14 Since the war the claims for sickness benefit have again risen, but the cost in 1925–26 showed that, on the average sickness among men was still considerably below the level of 1913–14. Among women the indications are less satisfactory, the figures suggesting that within a short period the earlier level will again be reached Comparing the sickness experience of a representative sample of men in the years 1921–23 with late nineteenth-century experience such as that of the Manchester Unity of Oddfellows in the years 1893–97, Sir Alfred Watson remarked on the improvement shown in the health of the community. the "rate of sickness" having fallen on the average by about 20 per cent He traced this to a large reduction. at all ages, in the proportion of the insured who claimed benefit; among men of ages 40 to 45. 160 in 1000 drew benefit in 1921–23 against 246 in 1000 in 1893–97. The duration of sickness on the other hand, has increased, the new average at the ages cited being 5 0 weeks per case against 4 3 weeks shown by the older tabulation. Special and not unsatisfactory causes may explain these features: they do not necessarily indicate any real increase in the length of incapacity Among unmarried women the proportion who fall sick is, as a rule. somewhat less than among men of the same age but the duration of incapacity is much longer. and on the whole, therefore, the average amount of sickness per insured woman is greater than among men Among married women, both the number claiming and the duration of the claim are relatively greater than among the unmarried; the duration of sickness benefit in the case of a married woman claimant averages in fact the very high figure of 8¾ weeks Disablement benefit (which is entered upon when sickness benefit has been paid for 26 weeks) is found to be an increasing quantity among all sections of the insured This said Sir Alfred Watson was expected by the promoters of the scheme as it grew to maturity and so far as men are concerned the cost is well within the expectation indicated by the older friendly society experiences The extent of the claims of women in respect of disablement benefit, however, is occasioning some concern Taking men and women together it is estimated that about 200,000 persons are now permanently disabled and drawing benefit from the approved societies Sir Alfred Watson went on to explain the seasonal variation of sickness, the claims made in the winter months average from 50 to 100 per cent more than the summer minimum. The claims for maternity benefit bring out clearly the changes which are occurring in the birth-rate, among the wives of insured men in the years 1919–23 the claims were 88 per cent of those expected by the financial standard The birth-rate (compared with the married population at the reproductive ages) has thus fallen by about 20 per cent since the beginning of the century, while the proportion of the married in the population has substantially grown, the increase in this respect being 20 per cent at the ages 20 to 25, 10 per cent at ages 25–30, and 5 per cent or more in other age-groups In comparison with the birth-rates among wives of insured men the great majority of whom are not employed outside the home, Sir Arthur Watson finds the birth-rates among employed married women to be significantly low; the proportion varied with age being, for example, 69 per cent. at ages 25 to 30 and 61 per cent at ages 30 to 35 His address, although expressly stated to be a statistical review, was felt to be very enlightening on some of the social implications of our health insurance system

CONTINUOUS RECORDS OF BODY TEMPERATURES

PROBABLY few clinicians realise the numerous pitfalls that exist in clinical thermometers until they read of the early struggles and failures of those who were pioneers in the subject [1] Apart from the experimental work of many investigators who have striven to provide a satisfactory clinical method of recording temperatures, a small body of workers have made, with almost infinite patience experiment after experiment to obtain continuous temperature records throughout the 24 hours. With these efforts the names of Lombard and Clifford Allbutt, Gamgee and Sims Woodhead will always be associated Gamgee began with a thermocouple combined with a photographic recording apparatus which consisted of a revolving drum covered with a sensitised bromide paper. Subsequently the evolution of the Thompson-D'Arsonval galvanometer enabled him to advance his methods a stage further On Gamgee s death, Woodhead who had previously been interested in the subject. returned to the work and was joined by Dr P C Varrier-Jones The continuous photographic recorder was discarded in favour of the quasi-continuous Darwin thread recorder with a d'Arsonval galvanometer, an apparatus which gives an inked dot on the revolving paper of a drum at regular intervals Finally an electric resistance thermometer was devised consisting of a fine platinum wire wound round two strips of mica notched at both sides and the whole enclosed in a silver tube without coming into actual contact with the platinum wire This thermometer coil is connected by flexible wires (with "compensating" leads) to a Wheatstone bridge on which the resistance can be measured by means of the defection of a galvanometer As the electrical resistance of the platinum wire varies with the temperature it is possible. by measuring this resistance to determine the temperature of the platinum which thus acts as a thermometer Recording is carried out with the Darwin thread recorder as with the later models of the thermocouple thermometer Full working details for the use of this apparatus are given in the book. The temperatures are taken per rectum. With the use of this apparatus quasi-continuous temperature records have been made from patients lying in bed in Addenbrooke's Hospital, Cambridge, whilst the complete recording apparatus was worked in the Pathological Laboratory a third of a mile away Dr Varrier-Jones has recently published a historical summary of his work on this subject and of that of his predecessors in a book where he also supplies observations made by himself and by others on the temperature in man and in animals in health and disease He has applied these observations to the study of the tuberculin reaction in cattle and to the early diagnosis and prognosis of tuberculosis in man, showing how these more accurate methods of recording temperatures assist the physician in detecting the very early signs of activity of the disease While it is not likely that the quasi-continuous temperature record can be applied on any large scale in clinical medicine, its use may, in the hands of careful and accurate workers, elucidate some of the problems which confront those who have to deal especially with chronic pyrexial diseases For instance, a comparison is needed between the value of the various laboratory methods for detecting early signs of activity in tuberculosis and the methods of an accurate delicate thermometry

BENZOIC ACID IN FOODSTUFFS.

THE Public Health (Preservatives, &c , in Food) Regulations, 1925, came into force in January last as regards their main provisions Boric acid, and to a lesser extent salicylic acid, were the main preservatives used by food manufacturers, but these are now prohibited. On the other hand, benzoic acid is permitted in certain scheduled foodstuffs, provided that the amount present does not exceed the specified limits Benzoic acid hitherto has not been extensively used for food preservation, and the report by Dr M S. F Monier-Williams,[1] recently issued, is timely as this substance will require more attention from food analysts The available methods for the separation of benzoic acid from foods involve either extraction of the acidified foodstuff with solvents, and recovery of the benzoic acid by evaporation of the solvent, or steam distillation In the solvent method preliminary treatment is necessary to remove proteins, fats, and other interfering substances, and to obviate the difficulties caused by the formation of troublesome emulsions Removal or destruction of proteins is almost always necessary as they are liable to cause emulsions on extraction with solvents, and also to retain benzoic acid The removal of the proteins by precipitation may lead to loss of benzoic acid in several ways which the author discusses With foods containing much fat it is probably safer to separate the fat, and to extract benzoic acid independently from the fat and from the fat-free residue Steam distillation is successful with non-fatty foods if certain precautions are observed The author describes a new method of steam distillation available for the determination of benzoic acid in fruit and vegetable products This is based on the observation that benzoic acid is readily and completely volatile in steam when the liquid in which it is present has previously been saturated with salt This method is described in detail and the quantitative results obtained suggest that it is one of great accuracy for the types of food for which it is proposed to be used The separation of benzoic acid from volatile fatty acids is a matter of some difficulty It is only in rare cases that direct extraction yields a product sufficiently pure for titration or weighing, without further treatment The various purification methods are discussed and sublimation is considered the best and most reliable method It is evident that the analytical difficulties involved in the determination of benzoic acid are considerable As regards the tests for benzoic acid, Mohler's test is described as the most delicate, while the ferric chloride test is more characteristic but somewhat less delicate The most characteristic test is Jonescu's, if we except those which depend on the sense of smell There is, of course, to be borne in mind the possible occurrence of benzoic acid in nature, but Dr Monier-Williams has only found it in one edible fruit (the cowberry or red bilberry) to any appreciable extent, certain substances, however, occasionally met with in foodstuffs may give reactions similar to those of benzoic acid, and care is therefore necessary in applying confirmatory tests

PLASMOCHIN

IT is now some time since we first recorded[1] the claims made for plasmochin, a synthetic compound produced by H Horlein in the Bayer laboratories at Elberfeld and recommended for the treatment of malaria The drug was obtained by adding various side chains to the quinoline ring which is also one of the essentials in the basis of the quinine molecule Chemically speaking, plasmochin is ethylamino-quinoline hydrochloride Our knowledge of its action is really based upon the action of quinine on the *Proteosoma præcox* infection of birds, and the preliminary experiments were performed by W Röhl on hundreds of artificially infected canaries using as a therapeutic standard the effect of quinine on this plasmodium, which had already been studied In this way it was shown that plasmochin exerted a parasitotropic action about 60 times greater than that of quinine, and the peculiar fact emerged that plasmochin has a far more rapid and destructive action upon the gametocytes, or sexual forms of the parasites, than upon the immature schizonts In 1925 F Sioli began to test the therapeutic action of plasmochin (Beprochin, as it was then called) on lunatic patients artificially infected with benign tertian malaria The doses attempted ranged from 0 05 to 0 25 g daily, the latter dosage, however, proved too large The patients rapidly developed a livid cyanosis of the face, lips, and especially the nails There were evidently toxic phenomena which, it was thought, could be eliminated by smaller doses Later in August, 1925, P Muhlens was able in Hamburg to observe the action of plasmochin upon 134 cases of naturally acquired malaria, and substantiated in the main the specific action of the drug upon the benign tertian parasite Under its influence the crescents, or gametocytes, of the subtertian form disappeared with great rapidity, but parasitic relapses with schizonts were apt to occur in *P falciparum* infections, so that the action of plasmochin had to be reinforced with quinine The best dosage was found to be 0 1 g daily, given in five doses of 0 02 g each At first the drug was exhibited in capsules, but latterly in tablet form Better results were obtained in subtertian malaria by combining it with quinine This was known as plasmochin compound, a tablet consisted of 0 01 g plasmochin with 0 125 g quinine sulphate, and six tablets were taken daily During 1926 Dr P Manson-Bahr, as related on March 2nd, at a meeting of the Section of Tropical Diseases and Parasitology at the Royal Society of Medicine, treated 18 cases of malaria with plasmochin and 10 with plasmochin compound at the Hospital for Tropical Diseases in London Exercising great care in clinical observation of the cases, besides making daily examinations of the blood, he has been able to confirm to a great extent the observations already made in Hamburg In benign tertian infections, he states, a dosage of 0 08 g plasmochin daily for five days caused rapid disappearance of the parasites with a very rapid reduction in the size of the spleen In subtertian malaria the crescents disappeared, as a general rule, within four days, but parasitic relapses were very liable to recur with the therapeutic doses mentioned In the latter infections, also, cyanosis developed in three cases, being associated with methæmoglobinuria in one of them This curious toxic state is due to the formation of methæmoglobin from the corpuscular -

[1] THE LANCET, 1926, ii , 765, 1279

hæmoglobin, and may be compared to potassium chlorate intoxication In plasmochin compound, however, the addition of small amounts of quinine seems to counteract these defects, and the results in 10 cases were equally efficacious in both benign and subtertian infections Dr Manson-Bahr concludes that plasmochin has to be regarded as the first of a new series of antimalarial synthetic drugs, and not as the climax of what has already been accomplished The future, he considers, is distinctly hopeful as regards the synthesis of a still more efficient antimalarial compound

HOSPITAL BEDS FOR THE MIDDLE CLASSES

PROVISION of hospital accommodation for patients of the professional and middle classes is gradually being made Many of the great hospitals have either in fact or in preparation blocks designed for paying patients, and other smaller institutions are increasing the number of beds allocated to the middle classes We have often set out the difficulties which have to be overcome when a charitable foundation created to serve the sick poor accepts patients from another class; these difficulties do not arise when hospitals are designed exclusively, as was the St Andrews Hospital in Dollis Hill, for the treatment of the professional and middle classes This admirable institution is now appealing for funds to build a home for nurses and maids outside the hospital building, thus giving space for 12 or 14 more beds for adults and for a children's ward with 12 cots Another private hospital for the middle classes is being organised in connexion with the Ladies' National Clubs, which provide residential accommodation for many women and girls in London and the South of England A large house has been secured in South Kensington which is being equipped with a suitable operating room It will have 34 beds, of which 12 will be in separate private rooms, the men's ward with 4 beds, 3 women's wards with 2 beds in each, and 2 larger wards each containing 6 beds The prices will range from 4 guineas a week upwards, private rooms costing 6 guineas a week, including maintenance and nursing The operating room fee is to be a guinea It is hoped that the institution will be self-supporting, any profit made being used for its improvement or extension. The hospital will be under the supervision of a non-resident medical superintendent who lives near at hand, and will, when necessary, be able to procure for members the services of consultants at fees modified in accordance with the patient's means In order to be eligible for admission an entrance fee of 10*s* 6*d*. is payable by anyone who is not a registered member of the Ladies' National Clubs, the subsequent annual subscription being 21*s* Particulars of how to join the parent organisation may be obtained from the registered office, 11, Cromwell-road, London, S W 7. It is intended to have a Guest House near the hospital, running in connexion with it, so that friends of patients and members coming to London for medical advice can obtain accommodation there on moderate terms It is not clear what would be the position if all the beds at the hospital were occupied when an urgent case for admission among the members presented itself, but doubtless the management have foreseen the possibility of this and will provide against it No mention is made in the literature which has reached us of an X ray room or pathological laboratory; in fact the prospectus gives the impression rather of a moderately priced nursing home under medical supervision, with expert staff available at modified fees, than of a fully equipped modern hospital, which could hardly be a business proposition if run on such a small scale It will be remembered that an association with much the same aims, entitled the Professional and Business Women's Hospital League, was organised and flourished for some years on less ambitious lines—that is, the members when ill were accommodated by special arrangement in the St Andrews Hospital, Dollis Hill, or the South London Hospital for Women This new scheme, however, apparently caters for men as well as for women; it is not stated whether the affluent are ineligible or whether they will be freely admitted to the hospital on the standard terms, presumably the consulting staff will not be asked to reduce fees unless inquiry has been made into the patients' circumstances. We shall watch the development of the scheme with interest

TOOTH-POWDERS AND PASTES

IN contemporary dental literature the subject of dentifrices is but seldom discussed It almost seems as though the dentifrice is becoming an elegant toilet preparation rather than a pharmaceutical product, and that the manufacturers are being allowed to take the initiative in deciding what qualities are requisite in it A recent paper by Mr F N Doubleday[1] should remind the dental profession that the lead ought not to pass by default to those whose interest is purely commercial, and it also contains an interesting discussion of the ideal preparation Tooth-paste, he remarks, has largely replaced powder in the public esteem, and he suggests that the desire for a bland preparation has been overdone and that the detergent value of the dentifrice has suffered in consequence The prejudice against the powder probably dates from the experiments of W. D Miller, who showed that an abrasive powder might be—and often was—definitely destructive to the teeth But from the coarse powder we have gone to the other extreme, and the modern tooth-paste, though free from gritty particles which could be harmful, is so smooth that it fails to be detergent A second reason for the popularity of paste is the convenience and cleanliness of the tubes Assiduous use of it, however, often fails to whiten the teeth of heavy smokers or people whose teeth are irregularly placed, and there seems to be good reason for Mr Doubleday's contention that a properly compounded powder is preferable, as a cleansing agent, to a paste Powder, he points out, should be taken from a sprinkler or bottle, as the supply in a tin may easily become contaminated, especially where several people use a common stock This latter practice may be the means of spreading infection, for it is very doubtful if the antiseptics in any tooth-powder can keep it sterile in an open tin The ideal dentifrice should contain a cleansing agent such as precipitated calcium carbonate, which is also an antacid Sodium bicarbonate may usefully be added as a solvent of the mucus which helps to keep food debris in contact with the teeth Judging by the analyses made in THE LANCET Laboratories ten years ago[2] both chalk and soluble alkali were present in all popular forms of dentifrice As to the value of soap expert opinion differs, some writers advocating a content of 25 per cent, whilst H Prinz would limit it to 2 or 3 per cent to avoid damage to the salivary enzymes Mr Doubleday, judging by his prescriptions, agrees with Prinz As an antiseptic no dentifrice can have much effect on the bacterial content of the mouth; whatever it may be capable of doing in vitro, its constituents are so quickly diluted by the saliva that the action must always be very limited A taste of antiseptics, however, has a certain psychological value, and as Mr Doubleday points out, their presence may help to keep the powder free from accidental contamination, if thymol be used it may possibly exert some action on the growth of the leptothrix associated with the formation of tartar A point on which he lays stress is that a tooth-powder should not be kept for a long time, and should therefore be bought in small quantities There is, indeed, much to be said for the suggestion that dentists should get in the habit of writing their own prescription for dentifrices Mr. Doubleday holds strongly that the reaction should be alkaline Seeing that the organisms concerned in dental caries are acid-lovers and the primary stage of caries is the destruction of the enamel by acid, this seems rational enough, even if the alkali does not neutralise the acid formed by carbohydrate fermentation it can at least do no harm The idea that a dentifrice should be acid came from H P Pickerill, who stated that acid or sapid food substances caused a free flow of saliva of increased alkalinity, which is, perhaps, the ideal detergent agent He suggested that an acid dentifrice would act in a similar way, and this theory received considerable support In recent years, however, Pickerill's observations have been criticised by several observers, notably E C Kirk and F P Chillingworth, who point out that methyl orange, the indicator he used, is unreliable Chillingworth[3] came to the conclusion that an acid dentifrice does harm, since it forms an acid plug which seals up fermentable carbohydrate in any dental cavities and so promotes the extension of caries rather than its prevention It goes without saying that a properly designed tooth-brush and correct brushing are necessary in order that any dentifrice may act to the best advantage Cross brushing should be avoided, for even with a bland dentifrice it will eventually wear away the necks of the teeth But if the brush is worked away from the gums, and towards the crowns of the teeth, the interdental spaces are cleaned and the gums and necks are not injured Without accepting all the claims of the manufacturers it may be said that the dentifrice has a definite, if modest, place in dental hygiene, especially as nowadays the teeth are often irregularly placed, and the diet may lack the detergent elements which cleanse the mouth naturally by causing vigorous mastication

[2] THE LANCET, 1917, i, 29

CELL POISONING BY CARBON MONOXIDE.

THAT carbon monoxide has an effect on other substances present in living organisms than hæmoglobin was shown last year by Warburg, who found that the rate of oxygen consumption of yeasts and of a micrococcus was depressed by the presence of this gas In a recent letter to *Nature* Mr J B S Haldane states that he has extended these observations to the wax-moth, *Galleria mellonella*, and to the cress *Lepidium sativum* The behaviour of the moth in atmosphere containing as little as 2 per cent of oxygen is normal, but when the proportion is reduced to 0 8 per cent motion ceases if the other gas present is nitrogen (plus argon) When, however, carbon monoxide is the diluent, 16 per cent of oxygen is needed for normal behaviour and motion ceases at 8 8 per cent oxygen and 91 per cent carbon monoxide On admitting air recovery is rapid and complete, thus differentiating the action from that on hæmoglobin Cress seeds, which would germinate in atmospheres containing as little as 1 7 per cent of oxygen and grow poorly in 5 per cent, but almost at a normal rate in 10 per cent, in mixtures of oxygen and carbon monoxide did not germinate at all under 3 per cent of oxygen, only a few seeds opened at 7 per cent, and in 14 per cent growth was slow Whilst experiments showed that carbon monoxide was relatively less poisonous for cress than for moths or yeasts, Haldane concludes that probably "oxygen before it can be utilised for some at least of the oxidative processes in the cell, must combine with a substance possessing a lesser but well-marked affinity for carbon monoxide, these two gases combining with the same group in its molecule As this substance is found in higher animals and plants as well as bacteria and fungi, it is probably a nearly universal cell constituent" Warburg found that the compound produced, like carbon monoxide hæmoglobin, is dissociated by light These observations should be borne in mind in connexion with the more familiar immediate results of carbon monoxide poisoning The gas is likely to occur in any situation where carbon or its compounds solid, liquid, or gaseous is incompletely burned This may result not merely through inadequacy of air supply, but also whenever a flame is cooled unduly The New York State Department of Labour has called attention in *Industrial Hygiene* for February to the widespread incidence of this gas in works of all kinds In New York the air of 24 out of 31 garages contained carbon monoxide, whilst in 17 cases the percentage of this gas exceeded 0 1 per cent, which apparently is considered permissible, although it seems unduly high The blood of 29 out of 42 workers in garages yielded evidence of carbon monoxide short of the clinical symptoms of poisoning The danger of cellular poisoning arises also in connexion with the use in confined spaces of fire-extinguishers containing carbon tetrachloride, a liquid which, although very efficacious in extinguishing petrol fires, yields carbon monoxide in addition to phosgene, hydrochloric acid, and a variety of other poisonous products

MEDICAL REGISTRATION

UNDER this title a paragraph has been circulated by one of the press agencies purporting to give the views of the Editor of THE LANCET on the scope of the General Medical Council and its penal powers One important newspaper immediately offered the *Editor an opportunity* of correction, and the agency has offered to take the same course It is unfortunate that publicity should have been given in a marked way to a wrong description of the functions of the General Medical Council and of the Council of the British Medical Association, while the words of the speaker, if accurately recorded, would have cleared up exactly the confusion

THE French Association of Anatomists has arranged to hold its meeting in London on April 11th to 13th, in cooperation with the Anatomical Society of Great Britain and Ireland The Congress will meet at University College. About 150 members of the two societies are expected, and as the French Society includes members from Belgium, Italy, France, Holland, Switzerland, Spain, Portugal, Poland, and Czecho-Slovakia, the Congress promises to be an international one such as hitherto has not been held in Great Britain On the evening of the 11th a conversazione will be held at University College One of the most interesting features of the meeting will be the reception by Mr Henry S Wellcome in his Historical Medical Museum on Tuesday, the 12th, from 8 to 11 P M On the following evening a dinner will be held at King's College Arrangements have been made for the members of the Congress to visit Cambridge as the guests of Prof J T Wilson There will be a trade exhibit dealing with scientific appliances and other technical equipment for anatomical study

ROYAL MEDICAL BENEVOLENT FUND —The annual meeting of the members of this Fund will be held at 5 P M on Friday, April 8th, at 11, *Chandos street*, Cavendish-square, London, W 1, when the officers and committee for the current year will be elected

THE LISTER CENTENARY —The centenary of Lord Lister's birth falls on April 5th, and on Monday, April 4th, the King will receive delegates at Buckingham Palace There will also be a reception by the Royal Society of Medicine in the evening The London programme for April 5th includes a reception by the Prime Minister in the large hall of the British Medical Association and a conversazione at the Royal College of Surgeons, whilst on April 6th there will be a memorial service in Westminster Abbey, followed by discourses at the Royal Society of Medicine, and a conversazione at the *rooms* of the Royal Society It is announced that the Listerian Society of King's College Hospital has been obliged to change the time of its celebrations from 8 P.M on Monday, April 4th, to 3 P M on the same day All old King's men and their friends are invited At Glasgow the Centenary will be kept on April 1st, details of the arrangements have already been published in THE LANCET (March 19th, p 622) The Edinburgh celebrations will chiefly be held on July 20th, when they will coincide with the British Medical Association's annual meeting We hope to publish in our next issue a full programme of the arrangements of the following week

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCXVI.

TREATMENT OF ACHALASIA OF THE CARDIA (SO-CALLED "CARDIOSPASM")

II.*—MEASURES FOR RELIEF.

Symptoms.—An individual, who has generally never suffered from indigestion, one day feels that his food is "sticking" deeply below the lower end of his sternum. After a time the discomfort, which rarely amounts to pain, passes away, either spontaneously or after ejection of the food—ejection, not vomiting, as the stomach takes no part in the action, which is unaccompanied by nausea. The food is undigested and alkaline, unless it has been retained sufficiently long to have undergone fermentation, and it is mixed with more or less abundant mucous saliva. The ejection is generally a more or less voluntary action, which the patient often learns to perform whenever the substernal sensation becomes sufficiently unpleasant. The first attack may be followed by similar attacks after every subsequent meal, or there may, at first, be intervals of varying length, but eventually all intermissions cease. The patient learns to eat very slowly and to choose food of fluid and semi-fluid consistence. He slowly loses weight, but finally equilibrium is established, and he is often able to carry on his occupation, though with his strength and energy greatly impaired.

Though the symptoms are very often mistaken for gastritis or some other disorder of the stomach, a carefully elicited history and the examination of the ejected material should exclude such a diagnosis. The only condition giving rise to somewhat similar symptoms is cancer of the lower end of the œsophagus. In this, however, the onset is much more insidious, and the dysphagia gets rapidly and progressively worse without intermission till complete obstruction occurs after a comparatively short time; in achalasia, on the other hand, the obstruction is no greater at the end of ten years than it was at the onset, which is always quite sudden. In cancer loss of weight and strength are generally more rapid, and the condition rarely occurs before the age of 45 or 50, whereas achalasia may occur at any age.

The X rays at once settle the *diagnosis*, the œsophagus is found to be greatly dilated, and, if it is previously emptied by a tube or by the voluntary ejection of its contents, the whole of the opaque meal is seen to accumulate in the œsophagus. In spite of violent, but intermittent, peristalsis nothing passes through the cardiac sphincter till the food forms a column about 8 in. in height, when a fine straight line is seen passing from about the level of the diaphragm to the stomach; this represents the lumen of the sphincter. In cancer the œsophagus is never greatly dilated and the whole of the opaque meal gradually passes into the stomach unless it is ejected, so that no large accumulation occurs. The lumen of the affected part is irregular in width and direction instead of being straight and uniform in diameter.

Occult blood is found constantly in the stools in cancer, but never in achalasia.

Œsophagoscopy is superfluous, as the diagnosis can be made with more certainty and much less unpleasantness by means of the X rays. The passage of an ordinary bougie is dangerous as well as useless, as the lower end of the œsophagus is so dilated that it forms a blind ending, from the left side of which the lumen of the cardiac sphincter passes; consequently a bougie generally misses the sphincter, and, unless great care is taken, it may damage the œsophageal wall. On the other hand, a flexible rubber tube filled with mercury, sufficiently heavy to find its own way without being pushed, passes through the closed sphincter without any appreciable resistance being felt—a further proof that no spasm is present. A growth, on the other hand, always forms an insuperable obstruction to the passage of the mercury bougie.

DILATATION OF THE SPHINCTER.

As it is presumably impossible to restore the power of relaxation to the closed cardiac sphincter, the object of treatment must be to dilate it to such an extent that it no longer offers any resistance to the passage of food into the stomach. This can be done most easily and with least discomfort and danger by means of mercury bougies. Rubber tubes varying in diameter between 33/64 and 46/64 in. (gauge Nos. 28 to 34), 31 in. long, and each containing the same weight of mercury (1 lb. 5 oz.), which has been found by experience to be sufficient to force the closed sphincter, are now obtainable.† It is best to pass the bougies on the first occasion during the X ray examination; it is then seen that they pass without deflection straight into the stomach. A mark should be made on the bougie at the level of the teeth when its two lower inches are within the stomach. Successively larger tubes are passed at a single sitting, and in most cases the largest one meets with as little resistance as the smallest. The patient is then instructed to pass the largest tube on himself before each meal. He finds at once that a meal taken after the passage of the tube enters his stomach without difficulty. For a few days the bougie should be retained in position on each occasion for as nearly a quarter of an hour as possible; then the time is reduced before lunch and dinner, and often, within a week, the midday passage can be given up entirely. Later the bougie is passed in the morning only, and the time it is kept down is steadily reduced. After a time, in favourable cases, the bougie is only passed on alternate days, then once a week, and finally its use is discontinued, but it is kept by the patient so that he can pass it if at any time he feels that some slight obstruction has returned.

Until recently the largest bougie I employed was No. 24; with No. 32, which, in spite of its alarming appearance, causes no more discomfort than the smaller one, improvement is much more rapid. But even with No. 24 sufficient improvement occurred in the majority of cases for patients to be able to discontinue its use after an interval of varying duration; in one patient, who was fortunate enough to have his condition diagnosed correctly on the actual day of the onset of symptoms, the passage of the bougie on a single occasion produced a complete and permanent cure. Another man was able to go through the hardships of four and a half years of active service in the war without any recurrence. Occasionally patients have found it necessary to continue to pass the bougie once or twice a day, but as they quickly get accustomed to it this is no great hardship; however, with the larger tube now in use, this will very rarely be necessary.

Two other methods of dilating the sphincter require mention. That in which a rubber bag is distended by hydrostatic pressure (Plummer's modification of Russell's method) is very painful, and has, on several occasions, led to death by splitting the sphincter. The other method is by forcibly dilating the sphincter by the fingers during a laparotomy; but the dilatation can be carried out equally well by the mercury tube without the disadvantage of an abdominal operation.

In one case of mine Mr. R. P. Rowlands divided the sphincter longitudinally, as in Ramstedt's operation for hypertrophic pyloric stenosis in infants. The patient is still completely well three years after the operation. He was the only patient I have had, in whom the passage of the mercury bougie had not given sufficient relief to enable him to regain sufficient strength to carry on his occupation, but I expect that the larger bougie now in use would have cured him also. The

---

[*] Part I., on General Considerations, appeared last week.

[†] From Messrs. Down Bros., St. Thomas's street, S.E.

seems rational enough, even if the alkali does not neutralise the acid formed by carbohydrate fermentation it can at least do no harm The idea that a dentifrice should be acid came from H P Pickerill, who stated that acid or sapid food substances caused a free flow of saliva of increased alkalinity, which is, perhaps, the ideal detergent agent He suggested that an acid dentifrice would act in a similar way, and this theory received considerable support In recent years, however, Pickerill's observations have been criticised by several observers, notably E C Kirk and F P Chillingworth, who point out that methyl orange, the indicator he used, is unreliable Chillingworth[3] came to the conclusion that an acid dentifrice does harm, since it forms an acid plug which seals up fermentable carbohydrate in any dental cavities and so promotes the extension of caries rather than its prevention It goes without saying that a properly designed tooth-brush and correct brushing are necessary in order that any dentifrice may act to the best advantage Cross brushing should be avoided, for even with a bland dentifrice it will eventually wear away the necks of the teeth But if the brush is worked away from the gums, and towards the crowns of the teeth, the interdental spaces are cleaned and the gums and necks are not injured Without accepting all the claims of the manufacturers it may be said that the dentifrice has a definite, if modest, place in dental hygiene, especially as nowadays the teeth are often irregularly placed, and the diet may lack the detergent elements which cleanse the mouth naturally by causing vigorous mastication

CELL POISONING BY CARBON MONOXIDE

THAT carbon monoxide has an effect on other substances present in living organisms than hæmoglobin was shown last year by Warburg, who found that the rate of oxygen consumption of yeasts and of a micrococcus was depressed by the presence of this gas In a recent letter to *Nature* Mr J B S Haldane states that he has extended these observations to the wax-moth, *Galleria mellonella*, and to the cress *Lepidium sativum* The behaviour of the moth in atmosphere containing as little as 2 per cent of oxygen is normal, but when the proportion is reduced to 0 8 per cent motion ceases if the other gas present is nitrogen (plus argon) When, however, carbon monoxide is the diluent, 16 per cent of oxygen is needed for normal behaviour and motion ceases at 8 8 per cent oxygen and 91 per cent carbon monoxide On admitting air recovery is rapid and complete, thus differentiating the action from that on hæmoglobin Cress seeds, which would germinate in atmospheres containing as little as 1 7 per cent of oxygen and grow poorly in 5 per cent, but almost at a normal rate in 10 per cent, in mixtures of oxygen and carbon monoxide did not germinate at all under 3 per cent of oxygen, only a few seeds opened at 7 per cent, and in 14 per cent growth was slow Whilst experiments showed that carbon monoxide was relatively less poisonous for cress than for moths or yeasts, Haldane concludes that probably "oxygen before it can be utilised for some at least of the oxidative processes in the cell, must combine with a substance possessing a lesser but well-marked affinity for carbon monoxide, these two gases combining with the same group in its molecule As this substance is found in higher animals and plants as well as bacteria and fungi, it is probably a nearly universal cell constituent" Warburg found that the compound produced, like carbon monoxide hæmoglobin, is dissociated by light These observations should be borne in mind in connexion with the more familiar immediate results of carbon monoxide poisoning The gas is likely to occur in any situation where carbon or its compounds, solid, liquid or gaseous is incompletely burned This may result not merely through inadequacy of air supply, but also whenever a flame is cooled unduly The New York State Department of Labour has called attention in *Industrial Hygiene* for February to the widespread incidence of this gas in works of all kinds In New York the air of 24 out of 31 garages contained carbon monoxide, whilst in 17 cases the percentage of this gas exceeded 0 1 per cent, which apparently is considered permissible, although it seems unduly high The blood of 29 out of 42 workers in garages yielded evidence of carbon monoxide short of the clinical symptoms of poisoning The danger of cellular poisoning arises also in connexion with the use in confined spaces of fire-extinguishers containing carbon tetrachloride, a liquid which, although very efficacious in extinguishing petrol fires, yields carbon monoxide in addition to phosgene, hydrochloric acid, and a variety of other poisonous products

MEDICAL REGISTRATION.

UNDER this title a paragraph has been circulated by one of the press agencies purporting to give the views of the Editor of THE LANCET on the scope of the General Medical Council and its penal powers One important newspaper immediately offered the Editor an opportunity of correction, and the agency has offered to take the same course It is unfortunate that publicity should have been given in a marked way to a wrong description of the functions of the General Medical Council and of the Council of the British Medical Association, while the words of the speaker, if accurately recorded, would have cleared up exactly the confusion

THE French Association of Anatomists has arranged to hold its meeting in London on April 11th to 13th, in cooperation with the Anatomical Society of Great Britain and Ireland The Congress will meet at University College About 150 members of the two societies are expected, and as the French Society includes members from Belgium, Italy, France, Holland, Switzerland, Spain, Portugal, Poland, and Czecho-Slovakia, the Congress promises to be an international one such as hitherto has not been held in Great Britain On the evening of the 11th a conversazione will be held at University College One of the most interesting features of the meeting will be the reception by Mr Henry S Wellcome in his Historical Medical Museum on Tuesday, the 12th, from 8 to 11 P M On the following evening a dinner will be held at King's College Arrangements have been made for the members of the Congress to visit Cambridge as the guests of Prof J T Wilson There will be a trade exhibit dealing with scientific appliances and other technical equipment for anatomical study

ROYAL MEDICAL BENEVOLENT FUND —The annual meeting of the members of this Fund will be held at 5 P M on Friday, April 8th, at 11, Chandos-street, Cavendish-square, London, W 1, when the officers and committee for the current year will be elected

THE LISTER CENTENARY —The centenary of Lord Lister's birth falls on April 5th, and on Monday, April 4th, the King will receive delegates at Buckingham Palace There will also be a reception by the Royal Society of Medicine in the evening The London programme for April 5th includes a reception by the Prime Minister in the large hall of the British Medical Association and a conversazione at the Royal College of Surgeons, whilst on April 6th there will be a memorial service in Westminster Abbey, followed by discourses at the Royal Society of Medicine, and a conversazione at the rooms of the Royal Society It is announced that the Listerian Society of King's College Hospital has been obliged to change the time of its celebrations from 8 P M on Monday, April 4th, to 3 P M on the same day All old King's men and their friends are invited At Glasgow the Centenary will be kept on April 1st, details of the arrangements have already been published in THE LANCET (March 19th, p 622) The Edinburgh celebrations will chiefly be held on July 20th, when they will coincide with the British Medical Association's annual meeting We hope to publish in our next issue a full programme of the arrangements of the following week

---

[3] Brit Dent Jour, Nov 15th, 1922

11 months of the first year The first month's rate is much the hardest problem—it has been practically stationary there since 1880—but a recent slight drop suggests further possibilities even in these deaths In the South of England and in London the neonatal rate now approaches that in New Zealand, but as we go north large local increases still appear As to the rest of the first year even rural districts in the South of England compare unfavourably with New Zealand

Social Implications in America

To return to the American field study This was carried out in eight large industrial cities The live births within a given calendar year (in every case between 1912 and 1915), 22 967 in number, were followed up by visits to the home, and only those included whose histories could be traced till death or the end of the first year of life The large number of social and economic factors involved are clearly so closely interwoven that a complete unravelling is hardly to be expected Age, nationality, and employment of the mother, order of birth, type of feeding, economic status as measured by the father's wages, interval since the last birth and before the next pregnancy, and antenatal and postnatal care of the mother are the main factors considered. In weighing the effect of any one of these, two or three of the others are allowed for by calculating the " expected " deaths on the basis of these classifications An important point made with regard to artificial feeding is that it showed an apparently cumulative effect during the early months of life It was less practised in the lower than the higher earnings groups, but seemed to be associated with greater danger in the poorer families

Deduction from Home Experience

The findings of the two most nearly cognate recent investigations in this country [2] are not in entire agreement on all points with the American experience Miss Elderton, for instance, failed to find any evidence that factory employment of women leads to abnormal confinements, while prematurity and increased neonatal deaths appeared to be associated with employment of the American mothers We are inclined to accept her conclusion that it is never safe to apply the results reached in one district to another district as regards the effect of things so dependent on local conditions as housing and women's employment It may also be noted that where the same tendencies are found the different methods of analysis used by the American and English authors do not lend themselves to exact comparison of the *amount* of the association.

It is no depreciation of studies such as these to say that they leave us with still uncertain knowledge as to the balance between hereditary constitution and environment and as to the exact relative weight of the different causes and effects of poverty in determining the viability of the infant Broad lines of attack are well marked out in this country and elsewhere, and we have a long way to go yet in our worst districts before we reach the level that New Zealand has shown to be possible

BIRMINGHAM GENERAL HOSPITAL—Discussing the decision to create a new hospital centre upon a site given by Cadbury Bros, at Edgbaston, the annual report of this institution states that Dr J G Emanuel, Mr J B Leathes, and Mr A. H Leaney, the house governor, are on the continent examining some of the most modern hospitals Until their report is available no decision upon methods of planning can be reached The Hospitals Council is working out a comprehensive contributory scheme

---

PUBLIC HEALTH IN THE IRISH FREE STATE.

A TRIENNIAL SURVEY

THE first report of the Department of Local Government and Public Health in the Irish Free State covers the period from April 1st, 1922, to March 31st, 1925, and deals with other branches of local government, such as Parliamentary elections and upkeep of roads, as well as with the public health Health insurance, lunacy, and the registration of births, deaths, and marriages are to be the subject of separate reports By recent legislation rural district councils and boards of guardians, with the exception of those in County Dublin, have been abolished and their duties transferred to county councils The current expenditure on poor relief is now, as a rule, spread evenly over the county area Public health expenditure and road maintenance are treated in a similar manner

Administration

Section 1 deals with general local administration. Under an Act, which became law in March, 1923, the Minister is empowered to dissolve local authorities which are not duly and effectually carrying out their duties, and to appoint in their place one or more Commissioners A more recent Act prescribes that the period of office of the Commissioners shall not exceed three years after which a fresh election of members of the local authority will be held The list of dissolved authorities includes several counties, the Dublin Corporation and Board of Guardians, and the Cork Corporation The Minister records that all the Commissioners have proved worthy of the trust placed in them

Infectious Disease

The public health section, which takes up about 18 of the 210 pages in the report, shows that the notification of infectious disease in many districts had fallen into disuse In the urban districts there were three cases of typhus in 1923–24, and one in 1924–25, while in the rural districts there were 59 cases in 1923–24 and 49 in 1924–25 The chronic area of typhus infection consists of a limited number of districts on the Atlantic seaboard, " where adverse social conditions, poverty, congestion and bad housing continue to persist " A considerable outbreak of enteric in Tralee was traced to ice-cream, and two outbreaks of enteric in Dundalk were traced to milk In the early months of 1924 diphtheria was unduly prevalent in the county borough of Cork In view of the prevalence of small-pox in England, medical officers of ports have been warned to be on the look-out and vaccination authorities have been advised to be active One case of small-pox was introduced from London in November, 1923, but there was no spread of infection

Temporary measures were taken in 1922 to meet the scarcity of qualified public analysts, compliance with the full standard of technical qualifications has now been resumed Whole-time county medical officers of health and veterinary officers are to be appointed

Maternity —School-children

The county and county borough councils were reminded by circular letter in June, 1923, of their duties as supervising authorities of midwives, and reference is made to the fact that the mortality from puerperal fever and childbirth is disproportionately high in Ireland, and that practically all cases of blindness from birth are due to want of knowledge and skill on the part of those in attendance on the mother and infant The prohibition of unqualified midwives became operative on Jan 1st, 1924, and it is urged that in every notified case of puerperal fever there should be careful inquiry as to the character of the attendance A 50 per cent national grant is operation demonstrated the complete absence of any hypertrophy of the sphincter, which was 1½ in in length and constituted the whole of the intra-abdominal part of the œsophagus

Diet

The prolonged retention of food in the dilated œsophagus caused by achalasia of the cardia and the frequent production of irritating material as a result of fermentation give rise to catarrh and occasionally more severe inflammation of the mucous membrane However complete the cure of the achalasia may be, the hypertrophy of the œsophageal walls remains, but the dilatation gradually becomes less, so that the redundant mucous membrane is thrown into deep folds If catarrh is also present, food tends to be retained between the rugæ and the œsophagitis is likely to persist It is therefore necessary to give the patient a diet containing no pips, skins, or vegetable fragments which would be likely to be retained, he should chew his food thoroughly, eat slowly, and finish each meal by drinking half a pint of water or milk in order to wash the last traces of food into his stomach During the first week of treatment it is advisable to give him nothing but four feeds a day, each consisting of one pint of milk, which may contain a beaten-up egg, this is generally quite sufficient to cause a gain in weight of 2 or 3 lb in an emaciated patient

Many patients learn to eject the contents of their dilated œsophagus voluntarily Anyone who can do this should be encouraged to evacuate the œsophagus half an hour after each meal, and then drink half a pint of water and evacuate at once as much of it as possible As a rule a small quantity of food and a good deal of mucus are still present during the first few days of treatment, but the quantity of each gradually gets less When there is no longer any residue to evacuate and no water can be returned, the œsophagitis as well as the achalasia of the cardia can be considered to be cured In very long-standing cases with severe œsophagitis, if the patient is unable to evacuate his œsophagus voluntarily, it should be emptied and washed out with a rubber tube attached to a Senoran's evacuator half an hour after each meal, until all signs of œsophagitis and œsophageal retention have disappeared

THE CAUSES OF INFANT MORTALITY

A COMPARATIVE STUDY

The United States Children's Bureau has long been occupied with comparative investigations into infant mortality, the results of which have appeared in separate reports and scattered papers published during the last few years Dr R M Woodbury sums up the chief results in a handy volume[1] now before us As a background to these field inquiries he gives a short survey of the general infant mortality in the birth registration area of the United States and also in New Zealand The infant mortality-rate for New Zealand (white population only) is well known to be lower than that of any other country How much of this advantage is due to climate, virility of the race, comparative absence of large industrial undertakings, and how much to the legislative and educative measures in which New Zealand is much to the fore, is not easily determinable What is, however, clear, is that the climatic factor can easily be exaggerated, and that the large differences observed from place to place either between or within countries are within the power of man to prevent

Two Main Causes

The main causes that contribute to these differences are respiratory disease and diarrhœa, and the variations from year to year (which might be taken as some [illegible] asure of climatic and other extra-human causes) of me a [illegible] er are much greater than of the former Dr the latter of [illegible] is concerned with comparisons with his Woodbury the [illegible] we may digress a little to consider how own country ; spe[illegible] It was noted in these columns a we stand ourselves exac[illegible] ummer diarrhœa is not the cause few weeks ago that su[illegible] in Scotland This must not of high infant mortality ratio Scottish rate from diarrhœal be taken to mean that the [illegible] n the English This used infant mortality is lower than [illegible] ow, as is shown by the to be the case, but is not so [illegible] The [illegible] e are indebted to the accompanying graph for which 50 [illegible] for Scotland and General Register Office th[illegible]

The close approach of the curves m, [illegible] d the decline in this country in the last few years annual, [illegible] ntable nature both may be taken as a sign of the prev[illegible] ses of climatic of the mortality from this cause in spite of [illegible] ular course and other epidemiological factors The sec the [illegible] d Wales of the infant mortality-rate in England and [illegible] ses to differs considerably from one group of ca[illegible] another, but in most groups the most striking feature is the steep decline since about 1900

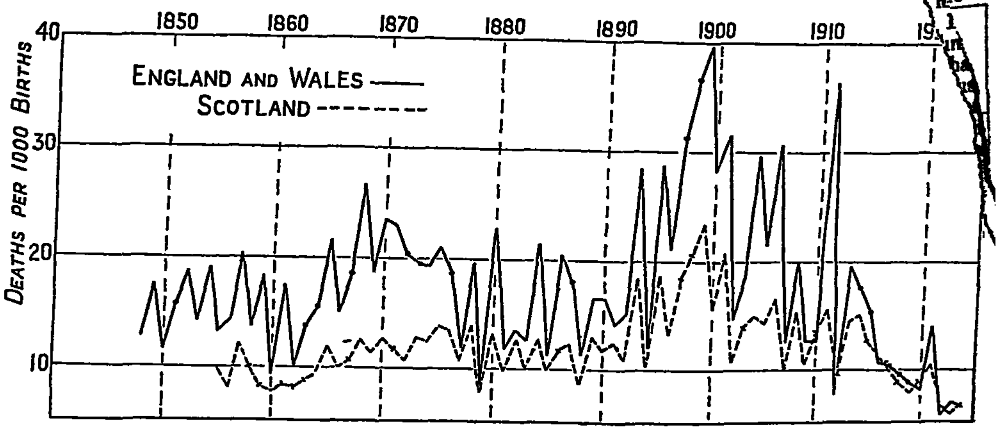

Chart showing the comparative number of deaths from infantile diarrhœa and enteritis in England and Wales, and Scotland over a period of 75 years

The New Zealand Example

Dr Woodbury gives an account of the intensive preventive work that is being developed in New Zealand, and points as a model to the urban area of Dunedin, which with some 1300 yearly births had a perfectly clean sheet as regards infant diarrhœal deaths for three successive years from 1922 to 1924. In New Zealand the problem is fast reducing itself simply to that of deaths in the first month of life, for while in 1924 out of every 1000 births 24 babies died n their first month, only 16 died in the remaining

SMALL-POX AND VACCINATION.

AMERICAN VIEWS AND PRACTICE.

IN a recent article[1] Surgeon J. P. Leake, of the United States Public Health Service sets out to answer a number of questions about small-pox, which he describes as the disease most completely preventable by public health measures He selected the questions because they are frequently asked by medical men, and though some of the answers are necessarily tentative, they deserve wide publicity

Technique of Vaccination

The best method of vaccination is, he considers the following —

> The skin is cleansed with acetone and is inoculated by shallow tangential pricking with a needle through a drop of small-pox vaccine covering an area not greater than one-eighth of an inch in diameter The needle must be new sharp and sterile It is not thrust into the skin but is held parallel to it with the forefinger and middle finger of the right hand above the needle and the thumb below, the needle pointing to the operator s left.
>
> The side of the needle point is pressed firmly and rapidly into the drop about 30 times within five seconds the needle being lifted clear of the skin each time. This rapid to and fro motion of lifting the needle and pressing it against the skin should be perpendicular to the skin and needle, and not in the long axis of the needle. The point is not driven into the skin, but during each descent the elasticity of the skin will pull a fraction of an inch of the epidermis over the point of the needle, so that the vaccine is carried into the deeper epithelium (cuboidal prickle-cell layer), where multiplication takes place most easily.
>
> If the skin has not been unduly rubbed in cleansing and if the motion is entirely perpendicular to the needle no signs of bleeding will occur and all evidence of the punctures will fade out in less than six hours Immediately after the punctures have been made the remaining vaccine is wiped off the skin with sterile gauze and the sleeve pulled down, the whole operation of puncturing and wiping taking less than ten seconds
>
> With strong vaccine a single pressure not infrequently gives a "take." When 30 pricks are made the percentage of "takes" is as high as with any other safe method For primary vaccinations where the mildest possible 'take" is desired, and where the attempt may be repeated if needs be the number may be reduced to ten or even to one prick.

The disadvantages of the method, says Dr. Leake, are (1) that the proper pressure may not be easily gauged at first, and (2) that the area covered may be too large If the needle is held at a tangent to the curve of the arm and if the direction of motion is quite perpendicular to the needle, it is difficult to make the rapid pressures too firmly. Motion from the wrist with the arm held rigid is usually more accurate than whole-arm motion The advantages of the method are (1) its mildness and painlessness, (2) its rapidity, (3) the fact that no control site is necessary, and (4) the immediate wiping off of the vaccine which makes the patient realise that no dressing is needed The ideal after-treatment is to keep the site cool and dry, so as to promote rapid formation of a firm crust and to avoid maceration and rupture of the vesicle A fold of sterile gauze may, if necessary, be attached to the garment but not to the skin Occasionally a severe 'take may require a few days of antiseptic dressings and primary vaccinations should be inspected about the fourteenth day to insure that desiccation is proceeding properly

As regards *site* Dr. Leake objects to vaccination on the leg because the leg is more exposed to moisture and contamination than is the shoulder On account of blood stasis, primary leg vaccinations in adults often heal slowly and cause temporary disability Vaccination scars on the arm leave only a 'sanitary dimple,' if performed as recommended.

Other methods—Any method is satisfactory which ensures that the vaccine is deposited in the deeper layers of the epidermis over an area not more than one-eighth inch in diameter, and avoids poulticing the developing vesicle. Intracutaneous injection of diluted vaccine virus is painful and even in good hands will often be subcutaneous, which makes it hard to interpret the results

Reactions following Vaccination

Dr Leake states that with a reaction of immunity which indicates full protection against small-pox, the broadest redness is reached and passed in 8 to 72 hours after vaccination With the accelerated or modified vaccination or vaccinoid, which indicates partial immunity, the broadest redness is reached and passed in three to seven days after vaccination With a typical primary vaccination indicating absence of immunity to small-pox prior to this vaccination the zone of redness rather narrow from the third to the seventh day begins a sudden spread about seven days after vaccination and reaches its broadest diameter in eight to fourteen days after vaccination rapidly disintegrating and disappearing thereafter These three types merge into each other all gradations being found in practice.

> "The prompter the maximum the higher is the immunity. Vesicles are formed in vaccinoid and typical vaccinia reactions but not with the reaction of immunity . . All three of the types are successful vaccinations provided the small-pox vaccine was fresh and strong All three not only indicate the grade of the previous immunity but increase the immunity as well All other results where proper technique was used indicate deficient vaccine Every vaccination should give a reaction."

The presence of a red slightly raised area at the site of vaccination 48 hours after vaccination is performed, does not necessarily indicate that the person vaccinated was immune to small-pox because:

(*a*) The vaccine used may have been weakened by time or temperature

(*b*) Accelerated reactions (vaccinoids) usually give on the second day the appearance described above which is similar to that of a reaction of immunity. Thus, even if an early reaction is seen observation about the fifth or seventh day is necessary to determine whether the reaction was that of immunity, with its maximum diameter of redness reached in less than three days, or an accelerated reaction (vaccinoid) with later maximum Even a vaccinoid reaction however, indicates some immunity.

(*c*) The trauma due to the mere mechanical act of vaccination may cause enough irritation so that the redness persists at the time of the early 48-hour observation independently of any specific reaction The "multiple pressure" leaves no traumatic reaction after six hours to obscure faint reactions of immunity.

Thus to sum up, the grade of immunity is not indicated by the amount of reaction, but by the *time* within which the local area of redness and infiltration of the skin reaches its maximum and begins to subside The quicker the maximum is reached and passed the higher is the degree of immunity indicated. The *amount* of the reaction depends on the skin reactivity of the person vaccinated and not on the grade of immunity. Probably any reaction which is marked within 24 hours will reach its maximum in less than 72 hours and therefore would constitute an immune reaction, but some of the most highly immune persons give the smallest reactions

A failure to take does not indicate protection for differences in skin receptivity may occur independently of the true immunity. For example very young infants are not as easily vaccinated as older children and some individuals may be resistant to a lot of vaccine which 'takes" generally in other individuals without, however, being immune against small-pox

Treatment of Sequelæ

Where secondary infection occurs the vesicle becomes purulent and extends As soon as a fair-sized areola has formed the maximum immunity has been attained and the use of an antiseptic will not diminish available for the provision of health visitors and about 130 district nurses are also engaged in this work County boroughs are being urged to formulate schemes of school medical service, but this matter is not being pressed in the case of counties pending the appointment of county medical officers of health A school medical service has been begun in the county borough of Cork, where the medical officer has made a general survey of the physical condition of 11,296 children attending 27 elementary schools, of whom 69 9 per cent were found to have defective teeth, 22 5 per cent defective eyes, 5 8 per cent defective nose and throat, 1 8 per cent defective ears, 9 4 per cent minor ailments, 11·8 per cent were unclean, and 8 per cent showed malnutrition Clonmel has also inaugurated a school medical service, including an eye specialist and a dentist, with the consent of the Tipperary County Council During the year ended March, 1925, approved arrangements for the provision of school meals were in force in 16 urban districts, including Dublin and Cork

---

[1] Public Health Reports, vol xlii, No 4 Jan 28th, 1927

Tuberculosis —The Blind —Venereal Disease

Approved tuberculosis schemes have been adopted in 22 counties and in Dublin and Waterford The recognised sanatoriums number nine, with an aggregate of 815 beds, but these are not all restricted to early cases Surgical cases of tuberculosis are admitted to 52 institutions, largely general hospitals, and the Irish Sisters of Charity have established a hospital with 70 beds in Dublin County for the treatment of surgical tuberculosis in children The total number of deaths from tuberculosis in the Free State during 1924 was 4582, and the patients receiving treatment under approved schemes numbered 10,131 It is thought that when the treatment scheme has been fully developed the cases treated will be from eight to ten times the number of deaths

There are four principal agencies for the welfare of the blind which receive Government grants, three of them in or near Dublin and one in Cork The schemes which county or county borough councils are required to formulate for the welfare of the blind have not yet been put into operation in any county, but the Commissioners for Dublin have adopted a scheme which came into operation in April, 1925

The schemes for the treatment of venereal diseases have so far only been resumed in Dublin County Borough and in Dublin, Kildare, and Wicklow counties During the year ended March 31st, 1925, the total number of patients dealt with at the V D clinics was 3174 These patients made 25,991 out-patient attendances and accounted for 7591 days of residential treatment in the hospitals

The section of the report devoted to poor relief shows that county hospitals have now been provided in nearly all the counties It is claimed that the placing of the local administration of the Poor-law on a county basis has relieved the burdens of the ratepayers

Dispensaries

Section 4 deals with medical charities, and it is therein shown that in March, 1925, there were 588 dispensary districts with a staff consisting of 634 medical officers, 30 apothecaries, and 656 midwives Since the abolition of the boards of guardians the distribution of free tickets has been carried out by members of the County Board of Health, home assistance officers and wardens, and steps have been taken to prevent the abuse of the free tickets

The report states that considerable progress has been made in determining scales of salaries for dispensary medical officers, and by March 31, 1925, scale salaries on a county basis were operative in all but seven counties The following are the average salaries of dispensary medical officers at the several periods mentioned —1904, £109, 1914, £130; 1924, £251 The real increase is trivial when one compares the cost of living now with what it was in 1914 and 1904 More satisfactory is the fact that dispensary medical officers are now entitled to four weeks' annual vacation, their substitutes being paid out of the rates The Report goes on to state that, in spite of the disturbances some years ago and the resulting difficulties of transport, the dispensary medical officers and midwives performed their duties to the sick poor with efficiency and sympathy

Housing

In Section 5 it is shown that the price of a five-roomed house is about £750, that the rent of such a house should be 8½ per cent of the capital cost, that the workman cannot pay more than one-sixth of his wages, and that consequently to secure an economic rent the capital cost should be twice the annual wage. This calculation indicates the considerable margin which must be provided from public sources, and one of the first acts of the new Government was to set aside £1,000,000 for urban housing Municipal authorities are asked to raise a sum of money by a 1*s* rate, secondly to obtain from local banks or other sources a short period loan equal to three times the produce of the aforesaid rate That having been done, the Government will make a contribution double the amount raised locally Thus under the scheme the municipalities will raise £125,000 from rates, £375,000 by loans, the Government will add £1,000,000, and there will thus be available £1,500,000 for the erection of 2000 houses at a total all-in cost per house of £750 Out of the 94 local authorities in the Free State, 71 have adopted housing schemes, and the building costs of the houses have averaged about £600 and £570 for five- and four-roomed houses respectively The houses are, as a rule, sold on the tenant-purchase system, with a maximum period of 40 years In the Dublin scheme the purchasers pay from 15*s* to 16*s* 6*d* weekly to cover purchase money, rates, insurance, and all other charges

Section 17 deals with the scheme of combined purchasing of the commodities required by local authorities By this scheme many advantages are obtained Much economy results from the adoption of uniform standards and patterns A list given in the report shows that the price of an article in the Government contract may be less than half of a similar article in a local contract made in 1922 The small purchaser under the new system buys under the same favourable terms as the large Under this scheme certain articles have been manufactured in Ireland for the first time

The Report, as a whole, is evidence of a great variety of work carried out with success in difficult conditions It is to be hoped that, in future issues, it will be possible to furnish a greater volume of statistical information, even if the Report is not allowed to swell to the bulk of the pre-War Reports of the old Local Government Board

---

ROYAL INTEREST IN HOSPITALS —The sympathetic interest taken by the Royal Family in all matters relating to hospital has been further illustrated Recently the Queen laid the foundation-stone of the Nurses' Home at the Metropolitan Hospital, Kingsland-road This institution, which has 137 beds, sets aside two wards, with Kosher kitchens for Jewish patients, and there is also a children's ward. Hitherto the 75 sisters and nurses have been inconveniently and uncomfortably lodged in detached and dilapidated houses full of passages so dark that they have to be lighted continuously —Princess Mary attended a reception given by the Lady Mayoress at the Mansion House in support of an appeal for £100,000 made by the British Hospital for Mothers and Babies at Woolwich It is desired to add a second wing to the present buildings with four large and four single-bed wards, two operating theatres and two nurseries, and to build a nurses' block with 30 bedrooms and dining and lecture halls, and a students' block with accommodation for 50 students It is hoped then to offer a full two years' course in midwifery, free to at least ten students The hospital, founded in 1749, was the first maternity hospital in London, and was also the first to train students in midwifery —Princess Arthur of Connaught has opened an extension of the Nurses' Training Home of the Essex County Nursing Association, Leytonstone and ultra-violet light treatments The dental surgeon visits weekly Among the works in progress are the installation of modern cooking appliances and the preparation of a convalescent block The purchase of Kinnaird Estate and Kinnaird Hill Farm has supplied the hospital with two-thirds of its milk and 2500 eggs as well as other farm produce and has provided occupation for many patients Infirm, sick, and recent male patients are nursed by women Eleven of the staff gained their M P A certificate during the year.

The *Aberdeen Royal Mental Hospital* records a satisfactory year of work in 1926 with an average of 800 patients resident including 33 voluntary boarders There was a recovery-rate of 31·29 per cent , and a death-rate of 6 65 per cent During the summer four large verandahs for open-air treatment were completed and later the electrical department was fully equipped with X ray, diathermy, and mercury-vapour apparatus Considerable benefit seemed to follow the sunlight treatment. 254 patients were seen during the year by the visiting dentist In the craft department a great variety of work is undertaken, and an operating theatre has been equipped

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED MARCH 12TH 1927.

Notifications—The following cases of infectious disease were notified during the week —Small-pox, 412 (last week 529), scarlet fever 1205 diphtheria 906, enteric fever 36, pneumonia, 2379 (last week 3375), puerperal fever 37, puerperal pyrexia 123, cerebro-spinal fever 17; acute poliomyelitis 11 encephalitis lethargica 32; dysentery, 7, ophthalmia neonatorum 147 No case of cholera plague or typhus fever was notified during the week

The drop in small-pox returns is due principally to the much smaller number notified (176) from the County of Durham 110 cases were reported from Wales and Monmouth, the position on March 14th being that 363 cases of small pox had been ascertained in Monmouthshire 288 of these belonging to Abersychan and 18 to Blaenavon in the Eastern Valley, while 27 came from Abercarn and the Western Valley A case is reported from Abergavenny Rural District but otherwise the epidemic is still confined to the industrial valleys On the date mentioned 99 cases had been removed to isolation hospitals belonging to various district councils

Deaths—In the aggregate of great towns including London there were no deaths from small-pox 1 (0) from enteric fever 72 (1) from measles, 8 (1) from scarlet fever 81 (14) from whooping-cough 43 (10) from diphtheria, 34 (10) from diarrhœa and enteritis under two years and 572 (49) from influenza The figures in parentheses are those for London itself The Registrar-General remarks that influenza which was increasing almost uniformly in different parts of the country until the week ended Feb 5th is now decreasing generally except in Wales, and it would appear that the worst phase has been passed For the week ended March 19th the influenza deaths show further substantial diminution, the figures being for the great towns 342 for London 33 Manchester 27, Birmingham 19, Newcastle-on-Tyne 15, Liverpool 14 and Wigan 13

Influenza in Scotland—The Scottish Board of Health reported on March 16th that in most parts of Scotland the influenza epidemic was definitely on the wane except in the counties of Fife and Ayr and in Orkney The source of infection in Orkney appeared to be a farmer who had recently returned from the south evidently in the last days of the incubation period He fell ill within 24 hours of his return and was visited by a considerable number of other farmers seeking information as to his business south All of them, with one exception subsequently fell ill with influenza, In a few places on the mainland outbreaks of influenza and of whooping-cough occurring at the same time had interfered gravely with school attendances for a number of weeks sometimes necessitating the closing of schools The bulletin of March 23rd notes the final strongholds of the epidemic in Fife and the extreme south-west corner of the country Elsewhere the epidemic is rapidly dying out

The Services.

B Rosair has been confirmed as Superintendent, Central Prison, Fatehgarh consequent on the retirement of Rai Bahadur Lala Mithan Lal Col H Ainsworth has been nominated by the Governor to be a member of the Bihar and Orissa Legislative Committee and Lt -Col I M Macrae has resigned his membership Lt.-Col W O Murphy has become Colonel vice Col J H MacDonald retd Capts H. A Khan and Malik Anup Singh have been created Majs Lt -Col G Hutcheson, civil surgeon United Provinces has been appointed Inspector-General of Civil Hospitals and Prisons, Assam, in succession to Col C H Bensley Col Hutcheson on return from leave, has also been appointed special officer in connexion with the Leprosy Dispensaries Scheme Lt -Col M. N Chaudhri retires from the service

ROYAL FREE HOSPITAL—For the first time this hospital has a credit balance, which amounts to £16 000. The whole of the money is, however, needed to pay off the debts of previous years

A NEW CLINIC AT PAISLEY— On Saturday last Princess Mary opened the Russell Clinic at Paisley, which has been given by Mrs Agnes Russell in memory of her two brothers The clinic is divided into two portions, one under the supervision of the Town Council dealing with tuberculosis maternity matters &c and the other under the control of the Education Authority The building contains a gymnasium and baths for cripple children dental rooms, X ray and ultra-violet ray apparatus and all the most modern arrangements for the curative treatment of juvenile ailments.

the protection In general, temporary moist dressings are preferable to powders or ointments

True generalised vaccinia practically never occurs, though morbilliform or erythematous eruptions are common about the time of the maximum reaction They disappear without treatment

Times of Vaccination and Duration of Immunity

Vaccination of infants, says Dr Leake, is attended with less general reaction and fewer complications than vaccination of older children It is, therefore, best done as soon after birth as practicable, preferably before teething There are four advantages to be gained by early vaccination (1) the "take" is apt to be mild ; (2) it tends to make the secondary vaccination, required at school age, a much less serious affair than if the school vaccination were primary, (3) protection against small-pox is gained for the pre-school years, (4) the scar of an infantile vaccination fades more completely than scars of primary vaccinations performed later

The immunity afforded is lost by different individuals at different rates Some need to be vaccinated more often than once in five years to maintain full protection, others may be vaccinated less frequently than once in 20 years and still maintain high immunity A primary vaccination with one successful revaccination, or even a single successful vaccination, will, as a rule, protect throughout life from the milder forms of small-pox, but this is far from being true in the severer outbreaks Second attacks of small-pox are rare, but do occur If there is danger of exposure to a severe form of small-pox, all persons who have not been vaccinated within one year successfully—that is, with vaccine known to be of full potency—should be vaccinated Successful vaccination performed on the day of exposure to infection will almost always give complete protection against small-pox, and vaccination up to a few days before the onset at least makes the attack milder than it would otherwise have been Vaccination during the few days before onset will allow the vaccination and small-pox eruption to develop simultaneously without either influencing the other

Epidemiology

In conclusion, Dr Leake points out that outbreaks of small-pox occur of all grades of severity, some with a mortality of 70 per cent among those attacked and some with a mortality of 0 01 per cent

"Since 1896 a mild form has been increasingly prevalent in the United States and countries in communication with the United States, having a fatality of about 0 1 per cent among the unvaccinated The strains of the disease present just previously had been much more severe, and from time to time outbreaks are now occurring with a fatality-rate of about 30 per cent in the unvaccinated Each of these strains in general breeds true to its respective type, and mild cases contracted from severe give rise in turn to severe nd fatal cases There is no definite grade of severity or of fatality that we can consider characteristic of small-pox, and it is probable that almost all of the epidemics called "alastrim," &c , have been mild forms of small-pox All forms of small-pox immunise against each other and all may be prevented by the same vaccination Exposure to a severe form is much more likely to give rise to infection than exposure to a mild form and it takes a higher grade of vaccinal immunity (more recent vaccination) to protect against a severe strain than against a mild strain

In moderately well-vaccinated communities, such as Germany, epidemics of mild type are entirely prevented, and outbreaks of severe type much diminished On the other hand, in poorly vaccinated communities, where isolation is nevertheless practised, such as England and the greater part of the United States, mild strains spread more diffusely than severe because they are not taken so seriously by those attacked nor by the public at large, and because the attack is not severe enough to keep the patient in bed and isolated The mildness of the form of small-pox commonest at present is one reason for endeavouring to make preventive vaccination as harmless and as mild as possible "

Dr Leake closes a valuable summary by pointing out that epidemics cannot be stopped by isolation without vaccination

Public Health Services.

MENTAL HOSPITAL REPORTS

Reports of work done last year in Scottish Mental Hospitals are reaching us with commendable promptitude

The *Royal Edinburgh Hospital*, Morningside, is always in the van of progress, and its 867 patients have every possible opportunity of recovery The great majority of them are on a voluntary basis, and the medical superintendent voices his protest at the ridiculous law which makes it a misdemeanour to treat voluntary patients in rate-aided institutions "Strange as it may seem," he remarks, "the existing Lunacy Laws . seem to have been devised with the perverse object of obstructing anyone desiring to obtain medical relief . . No one can be admitted to a public mental hospital until his disease has become thoroughly established or his conduct has become a public nuisance or a scandal Even then he is not permitted to receive treatment till his application for admission has been dealt with after the manner of the detention of a criminal " All concerned in this work will agree with his dictum that "such a method of treating a sick person and of handling a question of public health is cruel and an abomination to anyone inspired by medical sentiments and ideals " An outstanding event of the year at Morningside was the opening of a country nursing home for patients with nervous ailments For the poorer patients the managers have converted a block into a psychopathic hospital for 50 people, this is almost ready for use Very shortly the building of a new out-patient wing will be commenced, here it is hoped to hold a free daily psychiatrical clinic The mental out-patient clinic at the Royal Infirmary has been attended by 180 patients since it was opened 12 months ago, and is doing inestimable work in the homes of its patients as well as within the infirmary building The occupational therapy department continues to perform invaluable services, while the cinematograph and wireless often excite interest in apparently hopeless cases

The *Glengall Hospital* at Ayr houses 600 patients, and showed a recovery rate for 1926 of 36 per cent men and 40 per cent women, with a death-rate of 14 per cent The most notable feature among the new admissions was the improved standard of general health—the best ever recorded—while the proportion of senile cases dropped from 20 per cent to 7 per cent. The death-rate from general paralysis of the insane was remarkably high—45 per cent men and 9 per cent women The medical superintendent ascribes the record increase to greater sexual incontinence following over-reliance on antisyphilitic treatment and the use of contraceptives There were only two deaths each from cancer and tuberculosis Apart from mild epidemics of measles and gastro-intestinal catarrh, the general health of the community was good A number of patients had parole within and beyond the grounds Five nurses and four attendants obtained their M P A certificate during the year

The *Stirling District Mental Hospital* had a slight increase in the number of inmates (850) during the year ending May, 1926 The board is also responsible for 102 boarded-out cases. 144 mental defectives, and 82 patients in Poor-law institutions Twelve voluntary patients were admitted during the year, and eight of them were rate-supported There was a recovery-rate of 39 3 per cent and a death-rate of 11 7 per cent Twelve of the fatal cases were general paralytics Twenty-one patients were sent out on trial and all were able to stay at home There were no epidemics The new reception hospital is in use for recent cases ; operating and dental rooms have been equipped, and apparatus installed for X ray, high frequency, method of the uterus growth An experience of several years has shown that the growth test runs parallel with the clinical action On the other hand, the œstrus test discovered by Allen and Doisy, and on which the interest of the scientific world is just now focused, is a new feature. Its parallelism with the clinical action has not yet been demonstrated, and it would be premature to standardise ovarian preparations exclusively by that method, the more so as authors do not agree as to the real interpretation of rat or mice units Laqueur considers the proœstrus stage as typical, while others consider only the final stage (where cornified cells dominate the picture) as a positive reaction Under these conditions it is clear that enormous differences exist in the appreciation of the value of preparations Furthermore, the number of such units that are necessary to exhibit a therapeutic effect has not been determined Another point is that the question of the unity or plurality of the ovarian hormones is not yet cleared up Certain authors assume the existence both of an œstrus hormone and of a growth-promoting hormone, others advance the opinion that both hormones are identical Laqueur points out that his œstrus hormone is inactive when administered by the mouth, and from the fact that other ovarian preparations exhibit an action when administered internally he deduces the presence of other hormones This shows sufficiently that considerable confusion prevails on the subject Apart from the fact that Sistomensin is standardised by the uterus growth method, it may be stated that it also produces the œstrus test Consequently we feel bound to contradict the statement that none of the commercial material obtainable in Great Britain produces œstrus when injected into female rats

In conclusion, may we state that we feel justified in asking why these inaccurate statements should be made in connexion with the particular product, for the process of extraction of which we are the patentees —We are, Sir, yours faithfully,

THE PENALISATION OF THE TUBERCULOUS

To the Editor of THE LANCET

SIR,—The ventilation of this subject is overdue If one pauses to consider the advances in the treatment of tuberculosis which have been made during the last 30 or 40 years one must admit that the benefits of treatment, such as they are, have been brought about by individuals who have themselves suffered from tuberculosis I may mention in this particular two names, those of Saugman and Dettweiler I cannot say much about the conditions in this country because the persons concerned are still alive, but certainly the first and the best-run sanatoriums in this country were started by persons who had themselves been afflicted with this disease, in some cases, as I happen to know, very severely The faults of existing public sanatoriums are due largely to management by persons who know nothing first hand of this insidious malady The first requisite for a person who has the running of a sanatorium is surely that he should believe that he can cure his patients, and if this is so it follows that anyone who rejects, as a sanatorium doctor, a person who has been treated successfully for tuberculosis should not be allowed to treat tuberculosis If tuberculosis authorities will not employ their ex-patients, who can be expected to do so? And if they are to be debarred from getting employment, what is the use of treating them? I do not imply that doctors should combine an attempt to cure themselves with an appointment of any kind, I am referring to those who have taken the trouble to get well Such persons should not have to hide their health record from committees and the like

I am, Sir, yours faithfully,

March 21st, 1927

ERADICATION

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

DISEASES OF ANIMALS BILL

MR GUINNESS, Minister of Agriculture, in moving the second reading of the Diseases of Animals Bill said that Clause 3 would allow the slaughter of imported animals at the port which were found to be suffering from such a disease as tuberculosis on the order of an official of the Ministry of Agriculture He believed that this power was necessary, and he thought that the House would agree, when he told them that in one year they had 80 cows brought in with indurated udders, a very dangerous form of tuberculosis infection

MR BUXTON thought that the Minister was quite right to lay emphasis on the question of tuberculous cattle It was only logical now that they were beginning to deal effectively with tubercular milk that the efforts of local authorities and the Ministry should be supported in regard to the control of importation But he hoped that the efforts would be completely and solely aimed at the protection of public health Nothing was more important than a clean milk supply, and he hoped that the Bill would help in that direction

MR A V ALEXANDER said that local authorities in all the industrial areas were urging either that the Government should alter the amending Act of 1922 and make it compulsory on the Minister to admit cows, or that the Minister should take steps to make an order under that Act so that they could make up the loss to herds caused by slaughtering through the importation of healthy cattle from Canada

MR GUINNESS said that though it was proposed to take powers to deal with tuberculous animals at the ports it was not intended to make any amendment of the Act of 1922 as that would be quite outside the scope of this Bill

MR ALEXANDER said that it was true that the Minister had said that he desired these powers in order to deal with tuberculous cattle, but he would be aware that great dissatisfaction had been felt in connexion with the administration of the 1922 Act

The Bill was read a second time

NIGHT WORK IN COAL MINES

On Wednesday, March 16th, MR TINKER asked leave to introduce a Bill to prohibit the employment of young persons at night below ground in coal mines Leave was given to bring in the Bill which was read a first time

MENTAL DEFICIENCY BILLS

On Thursday, March 17th MR RHYS DAVIES introduced the Mental Deficiency (No 2) Bill, a measure to extend the law relating to feeble-minded and other mentally defective persons and to reconstitute the Board of Control The Bill was read a first time

On the 18th MR CROMPTON WOOD moved the second reading of the Mental Deficiency Bill He said that the Mental Deficiency Act of 1913, which was one of the most valuable social Acts ever passed, had one defect, namely, that only those who were mentally deficient from birth or from an early age came within its scope Those words "from birth" and "from an early age," as generally defined by magistrates and by medical practitioners, whether rightly or wrongly, excluded from the benefits of the Act several important classes of people who, he was sure, were never intended to be excluded when the Act was passed There were those, for instance, who suffered from encephalitis lethargica, meningitis, and frequent epileptic fits All those diseases might attack a person not at an early age only, but right through life Yet under these diseases people were often rendered mentally deficient Then there was another class which suffered accidents causing damage to the brain There were frequent cases where the early history of a man was lost In such cases it was impossible under the present law to deal with people who required treatment, and who ought not to be allowed to go about committing outrages on the community at large The Bill of last Session was intended to remedy this defect, but it was crowded out at the end of the Session and there was a good deal of criticism raised on the ground that it might interfere with the liberty of the subject The present Bill had been drawn to obviate any such charge The Bill had been drafted with the advice of the experts of the Ministry of Health and the experts of the Board of Control with the invaluable assistance of their president Sir Frederick Willis, and also with the help of the Association of Mental Welfare, whose president, Sir Leslie Scott, had given a great deal of attention to this subject Last Session's Bill limited the period within which menta

VENEREAL DISEASE IN THE MERCANTILE MARINE

To the Editor of THE LANCET

SIR,—Having spent over six years at sea, in more than a dozen steamship companies, there has been opportunity to note both the large number of cases seen of venereal disease among seamen and to deplore that something is not done to modify what is an ever-present evil

Examination of Crew—Before signing on this is supposed to be done by the ship surgeon I have never forgotten the words used by the Board of Trade official on more than one occasion to me "You might 'look' these men over, doctor" Of course too often this "looking over" is a purely perfunctory affair, with the result that men are signed on who, though not apparently unfit, soon make their appearance at the dispensary

Inspection in Foreign Ports—This also is a formality Men are drawn up in a line and ship surgeon and port doctor pass rapidly along, in haste to get it over and obtain pratique

The object of this letter is principally to suggest an aid in the matter of dealing with venereal disease while in foreign ports Statistics are given showing the benefit of early prophylactic treatment of cases in the United States Navy during the first 12 hours after possible infection Immediate treatment could hardly be carried out on board merchant vessels, where the surgeon is usually single-handed, but it should be obligatory on all men who have exposed themselves to infection to present themselves at the dispensary the following day for prophylactic treatment In addition a notice should be placed in all fo'c stles drawing attention to the danger run by men when in foreign ports the danger of promiscuous use of towels, pipes, shaving gear, tobacco-pouches, and even tooth-brushes The danger of inefficient treatment should also be drawn attention to, as I know from experience that men will often seek the aid of a chemist rather than report to the surgeon There are then too often disastrous consequences from wrong treatment, or advice from a man who is simply out for profit Capsules are sold at extortionate prices, and injections are dispensed with no knowledge of the strength to be used or suitability of the remedy Again, there is the untreated man, who becomes a source of grave danger on his arrival home

EXCISION OF THE METATARSAL HEAD

To the Editor of THE LANCET

SIR,—Like Mr George Perkins, whose summary of the results of excision of the metatarsal head, hallux rigidus, &c, I have read with interest in your issue of March 12th, I have found that although the patients have expressed satisfaction with the result of this operation, the condition as regards both comfort and function has not been quite satisfactory to the surgeon Ten years ago I removed the metatarsal heads for double painful bunion in a member of my household, and seeing the result daily over a period of years has made it clear that removal of the head of the bone has reduced the stability of the feet to a not inconsiderable extent The patient has to "pick her way" on irregular ground, has to keep the flexors of the four outer toes contracted, and so utilise these toes in place of the absent metatarsal head (or else be reduced to a plantigrade gait), and is no longer fit for long tramps as formerly

For the past eight years I have treated all cases of bunion and hallux flexus by excising at least ¼ in of the proximal end of the proximal phalanx of the great toe, and removing exuberant bone from the upper and outer aspects of the metatarsal head with bone forceps The results of this operation have been definitely better than of the orthodox excision of the metatarsal head, and I can, with confidence, recommend it for all conditions of arthritic deformity of the great toe

I am, Sir, yours faithfully,
Bradford, March 19th, 1927 JAMES PHILLIPS.

CAN TAR CAUSE PULMONARY CANCER?

To the Editor of THE LANCET

SIR,—I have read with interest Dr Robert Hutchison's letter in your issue of March 19th on the likelihood of tar being a cause of pulmonary cancer, and from 40 years study of cancer I think it is a very feasible hypothesis Two cases of pulmonary cancer that I have lately encountered would tend to bear this out—both in females, aged 76, both for years had been emphatic in their enjoyment of the warmth of an anthracite, iron, enamelled stove in their bedroom, and both must, therefore, have inhaled for many hours at a time the tarry vapours and dust incident to this method of bedroom heating The effect of such deleterious inhalations is desiccation of the mucous membranes, and then atrophy of the mucous glands, which are specially abundant on the posterior surface of the trachea and in the larger bronchi This exposes the denuded mucous membrane to irritation from the tarry and dusty fumes

It is difficult to understand how the persistent local application of tar can bring about epithelioma in a tissue, but my opinion is that it does so by dissolving out the thin layer of mucin that encases every cell, separating one cell from another, no matter how closely they are packed, even when so approximated as in the cutaneous tissues, thus allowing the individual cells to rub shoulders, so to speak, and thus an attrition of cells arises and cell division is set up with its dire consequences of infiltration, dissemination and metastasis

Wimpole street, W, March 22nd, 1927

THE PATENTING QUESTION

To the Editor of THE LANCET

SIR,—We desire to make the strongest possible protest against the article on the Patenting Question in your issue of March 12th, in regard to the specific reference to the patent of Herrmann and Fränkel (E P 113,311) As proprietors of the patent in question we are in a position to throw some light on the matter, relying upon your courtesy to publish these comments in your esteemed journal

For ten years we have been manufacturing according to that patent an ovarian preparation, "Sistomensin," and are selling it also in Great Britain through our concessionaires, the Clayton Aniline Co, Ltd, London, in any required quantities, the prices fixed by our concessionaires are considered by everybody to be fair and reasonable The reproach that through not granting a licence for this process we prevent the introduction of potent preparations is unjustified, because of the very fact that Sistomensin itself is recognised to be a potent preparation, as irrefutably shown by a considerable number of spontaneous scientific publications emanating from leading hospitals as well as from private practitioners, without mentioning the innumerable unpublished reports and communications from members of the medical profession We shall be glad at any time to submit this documentary evidence to your perusal

We may add that our product is standardised and approved physiologically by the recognised and approved

Mr **NEVILLE CHAMBERLAIN** Minister of Health, said that the failure of the Bill of last session to reach the Statute Book had created something like consternation in the minds of a very large number of people who had taken a great deal of interest in the efforts made from time to time to improve the conditions of mental defectives and to give the public such protection as was due to them He had received a great number of letters from Mental Deficiency Committees and other organisations interested in mental welfare expressing deep regret that the former Bill had to be dropped, and urging the Government to reintroduce it at the earliest opportunity. Mr **CROMPTON** had undertaken the task of reintroducing the Bill with certain modifications The new definition in the Bill of last year sought to bring in cases affected by such a disease as encephalitis lethargica He was inclined to think that the definition in the present Bill was too narrow, these cases might come on at a later stage than 18, and certainly beyond the age of 20 He preferred the original definition, but he would not press the extreme view if there were opposition, or if there was any danger of losing this Bill whose provisions were valuable as a whole. In this matter they had to consider the rest of the community and that was where he thought that Colonel Wedgwood had taken a one-sided view The Board of Control were always pressing local authorities to provide more accommodation for these unhappy cases and on the whole it was not backwardness of opinion that prevented them from doing so but the financial stringency of the present time He (Mr **CHAMBERLAIN**) had from time to time indicated his own view that if certain other institutions now administered by boards of guardians could be handed over to the councils of counties and county boroughs there might be found some temporary alleviation of the situation He hoped that before long it might be possible to consider something of that kind Meanwhile let them have certified all those who ought to be certified in order that even if there was no room for all of them they might be able to judge which were in the greatest need He hoped the Bill would receive a second reading without a division When it reached the Committee he had no doubt Mr **WOOD** would be ready to consider any suggestion for its improvement by way of amendment

After further discussion

Dr **VERNON DAVIES** said there was a definite distinction between a mentally defective and a case of mental disorder or lunacy Mental defectives suffered from what might be scientifically called amentia, while cases of mental disorder suffered from dementia The unfortunate thing was that in the case of amentia they could not expect a cure But while they could not cure mental defectives they could improve them Under the provisions of this Bill the interests of the mental defective were safeguarded at every point In cases of encephalitis in which they got arrested or incomplete development—the disease perhaps occurring in a brilliant child—something possibly happened to the cells of the brain which prevented their development It was accepted now by most people who were competent to judge that these cases only occurred in adolescence. The Bill was a marked improvement a definite step in advance He had to make again a protest which he had frequently had to make in that House, that medical men were criticised by members of the Labour Party in perhaps not too kindly a manner They had to bear in mind that experts had a certain amount of knowledge and presumably a greater amount than their critics. However wrong experts might be they ought to give them the credit of doing the best to the extent of their knowledge Medical men, by reason of their training possessed knowledge which was superior to that of the layman It was only fair that a certain amount of attention should be paid to them. It was not the wish of medical men to incarcerate anybody who had queer ideas or whims otherwise there might be a lot of people in danger This Bill was not only supported by the Board of Control, the Ministry of Health, and medical men as a whole, it had also the support of every organisation which was concerned with these cases

Lieut-Colonel **FREMANTLE** said he was strongly in sympathy with those who had spoken on the question of the liberty of the individual Colonel *WEDGWOOD* had touched on one of the most difficult points which medical men had to decide, and that was the question of where it became essential to interfere with the liberty of a child or boy for its own sake or for the sake of the community Medical men were the last to say at any moment that they were right in any decision or that they could lay down a hard-and-fast law Medical men were empirics in the last resort they must be But he suggested to Colonel **WEDGWOOD** that he had carried his argument quite far enough There was in the first place, the fact that mental defectives could be shielded and could at the same time enjoy great liberty Those who had expressed the fear that individuals were retained in these homes against their will would be glad to know that experience frequently showed that the reverse was the case It had been suggested that they should have an intermediate institution where a patient could be kept for five days of the week and allowed to go home at week-ends That system already existed in a number of institutions It was clear that there were 35,000 mentally defectives a number which might be enlarged with a higher standard or as some people would say a lower standard of definition There was accommodation for only 5000 in mental institutions On the other hand, a very large number of institutions under boards of guardians were being set free by the legislative measures of recent times, like the Widows' and Orphans' Pensions Act and so on This Bill gave importance to the need of putting under one local authority the Poor-law and other institutions in order that the greatest use might be made of the existing accommodation In the interests of the mental defectives themselves of their families, and of the public, he hoped that this Bill would be passed into law

The Bill was read a second time and committed to a Standing Committee

MIDWIVES AND MATERNITY HOMES (SCOTLAND) BILL.

On March 18th Mr **BARCLAY-HARVEY** moved the second reading of the Midwives and Maternity Homes (Scotland) Bill He said that the object of the measure was to reduce maternity and infant mortality in Scotland Firstly, the Bill provided for the registration of midwives so as to reduce the number of unqualified persons, secondly, the measure provided for the registration and inspection of maternity homes As regarded the question of midwives the position at present was regulated by the Act of 1915 In that year two Acts were passed, one being the Notification of Births Act which enabled authorities in Scotland to make arrangements for expectant and nursing mothers: the other was the Midwives Act which required midwives to be registered and supervised by local authorities under the supervision of the Central Midwives Board These two Acts had reduced the infant death-rate but unfortunately the rate of maternity mortality had not been reduced This was so unsatisfactory that a committee was appointed to inquire into the question, presided over by Lord Salvesen. Some of the figures which they had given in their report were extremely interesting The committee took the decennial period from 1855 From 1855 to 1864 the average death-rate per 1000 births was 4·9 From 1915 to 1922 the rate had increased to 6·2 While the two sets of figures were not quite comparable because the first were based on less accurate information than the last, they showed at any rate that this terrible evil was not decreasing in Scotland but was acutally increasing Lord Salvesen's committee made the definite statement that the evidence they received was unanimous on the essential point of this Bill The committee made a variety of recommendations and two of them definitely called for legislation on lines of this measure In addition the proposed authority was recommended by the Central Midwives Board in 1925 and 1926 The birth rate in Scotland was rather over 100 000 per annum and therefore the maternity death rate was 600 women a year The desire was to eliminate, if possible the unqualified midwife Difficulty had been experienced in administering the Act of 1915 because of the expression "habitually and for gain" and the first intention of this Bill was to get over that difficulty and try to tighten up the position Words had been put in which would leave sufficient elasticity to prevent hardship in cases where it was not possible to get a qualified midwife. Clause 3 was important because it entitled a midwife who had been suspended on account of the possibility of her carrying infection through no fault of her own, to be paid during the time she was actually standing off *Part II*, in brief, simply insisted that maternity homes should be registered and laid down a penalty for anyone who failed to register and yet carried on such a home

Sir **GEORGE BERRY** seconded the motion for the second reading of the Bill He said that Part I was a matter of public health and Part II. was really a matter more of public propriety He could assure the House having made careful inquiry, that the medical profession in Scotland approved entirely of the Bill. Part I. had been carefully considered by the Central Midwives Board and it also came before the Consultative Committee of the Board of Health In the final draft of the measure all objections had been met The question of maternity homes was a matter of social reform and he thought it must commend itself to every member of the House. The general opinion of Scottish medical graduates was that the reform proposed was wholly desirable and necessary

Major **ELLIOT** Under Secretary of State for Scotland said that the Bill was backed by members of all parties and he suggested that it should be given a second reading Any points of detail could be discussed in Committee

The Bill was read a second time and committed to a Standing Committee deficiency must have made its appearance to the ages at which mental development was going on. But it had been felt that this was rather dangerous Doctors said that mental development could only go on to, at the most, 25 years of age, but the opinion of doctors might vary, and he thought that it was quite rightly contended that this might interfere with the liberty of the subject In the present Bill, therefore, an age limit was fixed of 18 years The House might ask why 18 years had been selected? The question had been debated among scientists and in the end, though many people wished the age to be higher, it was decided that to avoid opposition to the Bill they had better put the age as low as possible At present the two alternative methods of dealing with mentally deficient children who left the special schools was either to shut them up in institutions or let them go into the world, and it had been thought desirable to provide in this Bill for another method—namely, that they should be placed under supervision He looked upon this effort to provide supervision for mental deficients under guardianship as one of the hopeful ways of dealing with this problem Clause 5 of the Bill dealt with defectives who were out under licence in connexion with the continuation of orders The object was to prevent the defective having to leave his work and return to his centre in order to be re-certified This provision would empower a doctor at the place where the boy was working to give the certificate necessary for the continuation order No boy would be certified by one medical practitioner alone After the medical practitioner sent in his report the case had to be investigated by visitors, who consisted of three Justices of the Peace, with one or more women added, and also a medical practitioner, and their report went up to the Board of Control Even then the Board could only re-certify the case when it was satisfied that the continuation order was in the interests of the patient himself Clause 6 made it the duty of local authorities to provide suitable training or occupations for defectives who were at their own homes under supervision This was important because idleness might lead the children into trouble Clause 7 enabled local authorities to take cases under contract from other local authorities whose own institutions might be too small Small institutions did not admit of proper classification and treatment and their multiplication was undesirable In conclusion the hon Member described visits he had made to the Manor Institution and the West Park Mental Hospital at Epsom. The first which was for mental deficients had, he said, a large mass of young people all as busy as bees Workshops were all over the place and the patients were working at different trades It looked like an ordinary public school with playgrounds, cricket grounds, and football grounds The West Park Mental Hospital, on the other hand, was controlled under the Lunacy Act It was the most improved institution of its kind, but among the patients were a lot of cases of encephalitis lethargica which could not be dealt with under the Mental Deficiency Act, 1913 These young sufferers were among elderly people and they had no great provision made for their training The House would agree that it was not good for young people to be put among middle aged people in a mental hospital who would probably teach them all sorts of moral perversions It was the power to put such children into mental deficiency homes that was sought under this Bill

Sir Douglas Newton in seconding the motion for the second reading of the Bill, said the Medical Committee of the Central Association for Mental Welfare, an organisation which represented all the chief workers associated with this branch of medical science, was anxious that the definition of a defective should be extended in the way suggested in this Bill in the light of the experience gained by the working of the 1913 Act Experience had shown that defectives had frequently been unable to receive the treatment which they ought to receive The Bill was not intended to deal with later ages, or with lunatics, as such, or with cases of mental disorder which supervened after maturity had been reached No doubt there would be some defectives even under this extended provision which would not be covered, but they thought that there would not be a sufficient number to justify a further extension than that provided in the Bill If there were any further cases it would be wiser, at any rate in the first place, to proceed somewhat slowly and leave such cases to be dealt with under the Lunacy Act The position of members of the medical profession was by no means satisfactory That was one of the principal reasons why the Bill had been brought forward In many cases medical men had found themselves unable to take the responsibility of certifying cases which were not congenital The medical profession in the administration of the Act of 1913 had shown, it would be agreed, a great deal of courage in dealing with what was admittedly a difficult situation, for they were inadequately protected under the existing law By raising the age to 18 much would be done to safeguard their position and to bring about a better state of affairs In the annual report of the Board of Control reference was made to the position of local authorities under the Act of 1913 Under that Act 124 local authorities—county councils and county borough councils—were charged with the duty of administration which entailed reporting upon the incidence of mental deficiency in their areas, and in notifying cases in need of guardianship and control. If the defective was merely in need of supervision—and there were many such cases—the local authority had now no power of notifying the case The Bill made an important and valuable extension of their power in this respect In 1924 it was ascertained that there were 48,778 mental deficients in the country, or 1 29 per 1000 of the population In 1925 there were 55,480, or 1 46 per 1000 of the population Ascertainment unfortunately tended to increase the figures, but there were great variations in different areas Oxford headed the list with 4 49 per 1000, but in Swansea the ascertainment only admitted to 0 12 mental defectives in that area It seemed not unreasonable to suggest that Swansea should take note of her responsibility under the 1913 Act The necessary funds were at present raised on a basis of 50–50—that was 50 per cent from the taxpayer and 50 per cent from the ratepayer This allocation would in future have to be reconsidered and more help would have to be given by the State to local authorities It had been suggested that with a view to preventing the growth of future generations of mental defectives preventive measures might be taken and that sterilisation would prove a cheap alternative to segregation He did not think that argument was a sound one Mental defectives nearly always required care and protection and sterilisation would not get over that difficulty Also they nearly always led useless and probably harmful lives and what was more they would be in a position to spread disease Little expense would be saved to the community Sterilisation could not be resorted to without compulsion and that would be quite rightly objected to He had been given figures showing that sterilisation would only result in from 3 to 5 per cent of the people now in institutions being allowed a greater measure of freedom, therefore he contended that it was not a practical solution, or one which the House, at any rate at the present time, need seriously consider It had been estimated that there were 160,000 mental defectives and it had been advanced that if they ascertained that there were more, the existing accommodation would prove inadequate He did not see why any class should be ineligible for treatment, and he urged the need for local education authorities taking action so that all cases which ought to be notified were notified before they reached the procreative age

Colonel Wedgwood, in moving the rejection of the Bill, said if they could divorce mental defective legislation from this detestable coercion, from forcing parent and child to be separated against their wish, nearly all his objections would go, but they would insist not on taking defectives whose parents wanted them to go to homes, but those whose parents did not want them to go To give experts the right to break up a family against the wishes of the parents was utterly unnecessary To do that under the guise of charity and benevolence seemed to him utterly damnable It was true that Sir D Newton did not approve of sterilisation, but his argument appeared to be that if they could not compulsorily sterilise these people they could at any rate, lock them up There were other ways of preventing undesirables from breeding besides surgical operations They could lock people up, and that was just as bad, but rather more hypocritical The argument for sterilisation was based on the idea that persons who were called morally defective were sure to have mentally or morally defective children Statistics proved nothing of the sort The border-line of eccentricity might go either towards genius or towards insanity If they took into their hands presumptuously the business of nature and of Providence they would take a responsibility which was impertinent even in the twentieth century, and one which was likely to lead the world in directions other than those intended by eugenist societies The definitions in this Bill, as in the old Act, were to be read by experts who, after all, were very often only expert in the imagination of others His reading of history filled him with horror at the thought of priestly authority Let them take care lest they built up in this generation by this worship and prostration before experts a new terror as horrible as the priestly system of old

Mr Rhys Davies (who was Under Secretary for Home Affairs in the Labour Government) supported the Bill He said that all who were interested closely in mental deficiency and listened to evidence and inquired into facts were compelled, whatever their views might have been beforehand, to come to the conclusion that something on these lines ought to be enacted by Parliament He did not agree with every word in the measure which he hoped would be amended in Committee s own use from opium lawfully in his possession smoking in company is illegal in the United es, Punjab, and North-West Frontier Province, nsumption of opium in any form is subject in Burma Assam to registration and individual rationing

Poor-law Medical Relief

Frederick Roberts asked the Minister of Health er he was aware that the majority Report of the l Commission referred to the unsatisfactory condition medical relief of some of the districts where the only n of obtaining an order for the doctor was from the ing officer, and that officials of his department stated r evidence before the commission that if the overseers abolished it would be necessary in the country districts their relief powers to some local officer or to the guardian; and whether in the light of these facts ould have the draft Order in Council reconsidered —ingsley Wood replied Such evidence as was given ers of the Department was to the effect that no ical hardship would result from the abolition of the ers; one Inspector suggested that the power of the ers might be given to the local Guardians The Order ncil has been made after lying on the Table for the ed period, and my right hon friend does not think it essary to reconsider the matter.

Pensions Hospital Patients and Vaccination

Robert Morrison asked the Minister of Pensions er he was aware that instructions were issued on the tant to the patients of the Ministry of Pensions tal Chepstow, that all patients must either be ted or take their discharge and by whose authority for what reason these instructions were issued —olonel Stanley (Parliamentary Secretary to the try of Pensions) replied: The instructions given were the terms suggested by the hon Member In quence of the recent severe outbreak of small-pox mouthshire, it was deemed necessary by my medical es to take all possible steps both to protect the patients e hospital at Chepstow and to obviate the risk of the e of this important institution which serves the needs ioners in Monmouthshire and South Wales as closure d have been the only possible course in the event of an eak of this disease occurring in the hospital With w instructions were issued to the Medical Superin directing his attention to the importance of the er and advising him that, in the case of any patient he considered not already adequately protected the disease revaccination should be secured as possible, if he considered it necessary and medically ticable. In the event of refusal on the part of a patient where the case was not, on medical grounds suitable vaccination, the case was to be dealt with either by the rary provision of alternative treatment or by isolation other means compatible with the welfare of the patient, h would obviate contact with other patients in the tion These instructions have been carried out with ul regard to the well-being of all the patients concerned whose care my right hon friend is responsible, and, I glad to say, have so far been effective

Infant Mortality in Tropical Colonies

Mr Herbert Williams asked the Secretary of State for Colonies whether systematic work was being undertaken the tropical colonies for the purpose of reducing the heavy e mortality —Mr Amery replied: Yes Sir, measures being taken in most tropical colonies on the lines that have successful in reducing infant mortality in this country, in many of them the results compare not unfavourably what has been accomplished here The governments cal colonies are fully alive to the importance of this Infant welfare clinics have been established women doctors, nurses, and health visitors who have special experience in this branch of medical work, are g appointed in increasing numbers

Gland Grafting in Animals

Sir Harry Brittain asked the Minister of Agriculture when he had had brought to his notice any of the experiments of Dr Voronoff in grafting an extra gland on to ock for the purpose of producing a finer and more ous type, and, if so, whether these experiments can looked upon as successful and would receive attention his department.—Mr Guinness replied I am aware Dr Voronoff's work on gland grafting, and I have nged with Dr Voronoff's concurrence for a small mission of scientific men to examine and report upon the imental work on sheep which has been carried out at Government breeding station in Algeria Owing to bad season, the visit of the commission has been poned until October or November, when the grafted ep will be available for examination.

Registration of Opticians

Mr Herbert Williams asked the Minister of Health the composition of the departmental committee on the registration of opticians —Sir Kingsley Wood replied The personnel of the committee is not yet complete but my right hon friend hopes to be in a position to announce its composition at an early date

TUESDAY, MARCH 22ND

Casual Vagrants and the Spread of Scabies

Mr Crawfurd asked the Minister of Health whether he was aware that at a recent meeting of the National Association of Vagrancy Committees, complaint was made that casual vagrants suffering from scabies were passed on from casual ward to casual ward, thereby spreading the disease; and whether he proposed to take any steps in the matter —Sir Kingsley Wood replied This complaint has not previously been brought to my right hon. friend's notice but he will make inquiries I may say that the attention of guardians has from time to time been drawn to this matter by circular and otherwise The regulations applicable to casual wards contain provisions enabling guardians to detect and deal with such cases and the guardians also have powers of detention

Poor-law Medical Relief

Sir Charles Oman asked the Minister of Health whether he was aware of the recommendation of the Royal Commission on Poor-laws to the effect that medical relief should be made more readily accessible and of the evidence of a witness speaking on behalf of the British Medical Association (Report, pp 282-4) to the effect that if doctors attended without an order the rule was that they did not get paid: and whether he could take steps to ensure that, in the case of medical assistance being rendered to any poor person on account of accident or sudden illness, payment should be made to the medical man although no order for relief might have been given by the guardians or the relieving officer —Mr. Chamberlain replied. The reply to the first part of the question is in the affirmative but I am not aware that at the present time any difficulty of the kind suggested in the second part has arisen I should be glad to consider any information my hon friend may have on the subject

---

Donations and Bequests—Dr Samuel Clarke Noble M R C S Kendal Westmorland said to be the oldest medical practitioner in the North of England, who died at the age of 89 years bequeathed £3000 to the master and scholars of Balliol College Oxford, for the foundation of an open classical scholarship to be known as the "Eric Raymond Noble Scholarship" £300 to the Medical Mission of the Church Missionary Society, £1150 to Dr. Barnardo's Homes for the erection of a cottage at the Girls Village Homes, £1500 to the Westmorland County Hospital for the endowment of three beds in the children's ward in memory of Hugh Percy Noble, Kathleen Maude Noble, and Eric Raymond Noble. The ultimate residue of the property—originally £38 807—as to one-third to Middlesex Hospital for a scholarship in remembrance of his son formerly anæsthetist at the hospital, to be known as the Eric Raymond Noble Scholarship; one-third to Balliol College for a classical scholarship, and one-third to Dr Barnardo's Homes for general purposes.—Miss Margaret Jane Brown, Glororum near Morpeth, Northumberland, besides other bequests left £500 each to the Victoria Blind Asylum Newcastle, and the Newcastle Infirmary —Mr John Cowan, who for over 50 years was the agent of the Free Church of Scotland and the United Free Church, left £201,766 Besides bequests to these institutions he left £1000 each to Longmore Hospital for Incurables, Edinburgh, and the Sick Children's Hospital Edinburgh; £500 to the Blind Asylum Edinburgh, and, after a life rent, £40 000 to the Edinburgh Royal Infirmary to endow a ward in memory of his father, Lord Cowan The residue is to be divided between the United Free Church for the Aged and Infirm Ministers Fund, and the Royal Infirmary, to equip, if thought practical, a ward or hospital for paying patients —Among other donations the late Mr. Howard Ellis, of Swallowhurst, Blackburn Park, Didsbury Manchester, left £1000 each to the Royal Free *Hospital, London*, and the Middlesex Hospital, £500 each to the London Hospital, the University College Hospital, London, the Manchester Royal Infirmary, the Ancoats Hospital, Manchester, and St. Mary's *Hospital* for Women Manchester.—*Miss Catherine Mary* Stewart, Winchcombe, Gloucester, formerly of Manchester, besides other *bequests, left £1000 to the* Winchcombe Hospital for the endowment of two beds.—*The Chelsea* Hospital for Women has received a bequest *of £1000* from the late Sir Squire Bancroft *to endow a bed in memory of the late Lady Bancroft.*

HOUSE OF COMMONS

Wednesday, March 16th

Dangerous Drugs

Mr Neil Maclean asked the Secretary of State for Foreign Affairs whether he was aware that the printing of document O C 294 (b) of the League of Nations, dealing with the traffic in dangerous drugs, had been stopped and all existing stocks returned to Geneva, and who issued the orders and what were the reasons—Sir A Chamberlain replied I have no official information on this subject, but I understand that the publication of this document is merely temporarily postponed pending revision

Poor-law Expenditure in West Ham

Replying to Mr William Thorne, Sir Kingsley Wood (Parliamentary Secretary to the Ministry of Health) stated that the Budget statement of the guardians of the West Ham Union for the half year ending Sept 30th, 1927 showed a total of common charges amounting to £759,892 This sum included £76,000 for lunatics, £1000 for vaccination fees, £7000 for maintenance in hospitals, &c, £6000 for drugs and medical appliances, and £370 for subscriptions to hospitals The income statement showed £709,078 accounted for by precepts, and £50,000 moiety of grants to be received from county councils of West Ham, East Ham, East Ham and Essex under the Local Government Act, 1888, and other receipts

Approved Societies and Dental Benefit

Mr Rhys Davies asked the Minister of Health what tribunal would determine any differences which might arise between a dentist and a regional dental officer, and under what authority would any decision be given by such tribunal—Mr Chamberlain replied The function of a Regional Dental Officer is to furnish an independent professional opinion for the guidance of approved societies and dentists in connexion with claims for dental benfit. If a dentist is dissatisfied with any action which a society, after consideration of the report of the Regional Dental Officer, may take, or propose to take, he may refer the case to the Dental Benefit Joint Committee whose jurisdiction both societies and dentists have, under the new arrangements, agreed to accept

Thursday, March 17th

Maximum Disablement Pensions

Mr Beckett asked the Minister of Pensions the number of men drawing 100 per cent disablement pensions in January, 1925, and January, 1927, or the nearest available dates—Major Tryon replied The number of men drawing pension at the maximum rate of 100 per cent. was in January, 1925, approximately 32,000 The number of the same class in January, 1927, was approximately 34,000.

Open-air and Hospital Schools

Mr Short asked the President of the Board of Education what was the number of open-air schools under the county and local educational authorities of Staffordshire , and the number of children in attendance—The Duchess of Atholl (Parliamentary Secretary to the Board of Education) replied There are at present two open-air schools in Staffordshire, and two hospital schools conducted on open-air lines The total number of children on the registers of the four schools, on March, 31st, 1926, was 158 The hon Member will, however, understand that the total number of children dealt with in institutions of this type during the year is very considerably larger than the number in attendance on any given date

Repair of Insanitary Houses

Mr Robinson asked the Minister of Health if his department took any action in compelling, or had authority to compel, local authorities to reinstate insanitary houses at the expense of the owners of such property which was a menace to the general health of the public and the tenants in particular—Mr Chamberlain replied Part I of the Housing Act, 1925, contains the provisions enabling local authorities to secure the repair, maintenance, and sanitary condition of houses at the expense of owners, and provision is also made for their enforcement by order of the Minister of Health if, after receiving a complaint and holding a local inquiry, he is satisfied that there has been default on the part of a local authority

Children and Vaccination

Dr Watts asked the Minister of Health the number of children who attained the age of 12 months during the year 1926, the number of those in respect of whom the parents furnished a certificate of successful vaccination or a certificate of conscientious objection, the number of those whose parents did neither, and the number of prosecutions—Mr Chamberlain replied Accurate information is not available as to the number of children who attained age of 12 months during 1926 The total number of b registered in England and Wales during 1925 was 710, but the vaccination returns in regard to the children b in that year are not yet quite complete The returns present to hand relate to a total of 708,500 children a of these 37,728 died unvaccinated Certificates of succe vaccination were furnished in respect of 313,450 child and declarations of conscientious objection to vaccinati in respect of 291,347 children As regards the remaini 60,975 children no such certificates or declarations w furnished I have no information as to the number prosecutions

Unhealthy Schools

Mr Short asked the President of the Board of Educati the number of existing elementary schools condemned unsuitable and incapable of improvement, and the numb of children attending such schools

Mr Barker asked the President of the Board of Edu tion whether he was aware that there were schools hou more than 500,000 children which were totally unfit for t purpose and should be closed forthwith, and what st were taken to see that these schools were replaced by bu ings of a more healthy type—The Duchess of At replied The number of schools on list A—that is scho which have been reported as unsuitable and incapable improvement—is now 623 The number of children the registers of these schools is about 160,000 and not, suggested by Mr Barker, more than 500,000 The lat figure is an estimate of the total number of children attendi the schools originally included in the lists A and B In number of cases the requisite action has already been tak and proposals have been received for dealing with a la number of other schools on the lists The programm which have been submitted indicate that authorities co template being able to deal with the bulk of the provid schools on the lists by the end of the programme peri and my right hon friend is now considering what furth steps should be taken to secure that the whole proble both as regards provided and non-provided schools, treated on a systematic basis

Wines from Bond for Medicinal Purposes

Major Braithwaite asked the Chancellor of Exchequer whether he would consider, in view of the seri epidemic of influenza, releasing from bond the requiremen of responsible druggists of sherry used for medicinal p poses—Mr Churchill replied I am informed that spec consideration is given by the Commissioners of Customs a Excise to applications for the delivery of wine to be u in the manufacture of medicated wines

Friday, March 18th

Rejection of Naval Recruits

Mr Hore-Belisha asked the First Lord of the Admira how many men presented themselves on an average e month for recruitment in His Majesty's Navy, and h many were rejected, and for what principal reasons Lieut -Colonel Headlam replied During 1926 the aver number of candidates who presented themselves e month for entry was 5100, and the average monthly num rejected was 4460 The main causes of rejection w defective vision, teeth and hearing, and being un educational standard

Rejection of Recruits for the Royal Air Force

Mr Hore-Belisha asked the Secretary of State for A how many men present themselves on an average ea month for recruitment in His Majesty's Air Force, a how many were rejected, and for what principal reasons Sir S Hoare replied The total number of men who p sented themselves for recruitment in the calendar y 1926 was 1028 Of these, 258 were rejected on medi grounds and 391 on other grounds such as educatio unfitness or age The principal causes of rejectment medical grounds were dental defects, deformity of fe heart disease, poor physique, respiratory diseases, defecti vision and ear diseases

Monday, March 21st

Opium Shops in India

Mr Gardner asked the Under Secretary of State for Ind the number of licensed opium shops in India the area opium cultivated and the parts of India in which opiu smoking was prohibited—Earl Winterton replied T number of shops in British India in 1925–26 was 58 with the addition of a small number in Delhi, Ajmer-Merwar Coorg and Baluchistan which in 1924–25 was 88 Th latest figure of poppy cultivation in British India sho 114,198 acres in the year ending Oct, 1925 in additio there was a small area of 1653 acres in the Punjab Hill The law in British India prohibits the sale of opium prepar for smoking, and also its manufacture except by an individu

Obituary.

JOHN BROWNLEE, M.D., D.Sc. Glasg., D.P.H.,

DIRECTOR OF STATISTICS, MEDICAL RESEARCH COUNCIL

The death from broncho-pneumonia, after little more than 48 hours' illness, of Dr John Brownlee, which occurred on March 20th, will come as a great shock to his numerous friends. He had not enjoyed robust health for some years, but he was actively engaged in research work only a few days ago and apparently in his usual health and spirits.

John Brownlee was born in 1868, a son of the Manse, and educated in the University of Glasgow where he had a brilliant career, securing first class honours in mathematics and natural philosophy in his Arts course and commendation both for M.B. and M.D. degrees. He graduated M.A. in 1889, M.B. in 1897, M.D. in 1898, and D.Sc. in 1907. He was also a D.P.H. of Cambridge, and some years ago the Faculty of Physicians and Surgeons of Glasgow conferred upon him the distinction of election to the Fellowship without examination. After graduation and the usual resident posts, Brownlee spent two years as resident physician in the Belvidere and Kennedy-street Fever Hospitals and then nine months as pupil assistant to the late Dr J. B. Russell in the Glasgow Health Office. This experience impressed him deeply, and Russell was for him one of those great men who, in Helmholtz's words, alter one's whole scale of values. In 1899 Brownlee was appointed medical officer of health of Guernsey, and although he held the post only 18 months this stay in an environment very different from that of a great industrial city also affected him deeply. In 1900 he returned to Glasgow as physician-superintendent of the Belvidere Fever Hospital and for the next 14 years (he transferred from the Belvidere to the Ruchill Hospital in 1908) he was mainly engaged in the clinical and administrative work of a large hospital for infectious diseases. In this work he was conspicuously successful. Although not a fluent lecturer he was an inspiring clinical teacher, and his old pupils remember gratefully their lessons learned at Ruchill. Brownlee found time, however, to apply his mathematical ability to medical and biological problems, and before his appointment by the Medical Research Council, in 1914, to be the first director of their statistical department, he had already published several important papers of a biometric character and won a reputation as a prominent exponent of the statistical method. From 1914 onwards Brownlee's professional interests were statistical and a bibliography of his work since 1913 includes no less than 45 titles. Many of these papers, such as his memoir on the epidemiology of phthisis and his investigation of the periodicity of epidemics of measles, involved an immense amount of detailed analysis and are of permanent scientific value. To the public he was best known for his enunciation of 33 weeks as the interval between epidemics of influenza and for his forecast based upon this assumption.

John Brownlee

"It is not possible," writes one of his colleagues, "within a few hours of the loss of a great investigator adequately to characterise the nature and value of his contribution to knowledge. Perhaps it may be said that the real value of Brownlee's life work was not so much in any important specific addition to knowledge as in the general character, the *quality* of his work. This may, at first, seem a hard saying, for in the mere A B C of literary composition Brownlee was deficient. His literary style was not very attractive and he had none of the power, so conspicuous in, for instance, the writings of Mr Udny Yule, of expressing a difficult mathematical argument in such a way that no attentive reader can fail to grasp it.

"But any reader who cares to surmount the superficial difficulties of Brownlee's style is inevitably conscious of a certain philosophical breadth of treatment which he will seek in vain in the writings of most statistical epidemiologists. The memoir on the epidemiology of phthisis or the report on the mortalities of birth, infancy and childhood, well illustrate this quality. A reader may dissent from every particular proposition and yet feel that the author has placed him under a great obligation, has obliged him to look at the problems from a loftier standpoint. There is a great gulf between acuteness and sagacity. Of that acuteness which enables a man to solve neatly particular problems—the mental analogue of the precision with which a terrier nips rats—Brownlee had little; he was not acute in the narrow sense but he was something more, he was sagacious. Of course, he had the defects of his qualities. People who did not know him intimately and sought guidance on some specific problem might be, and frequently were, exasperated by the way he would pass from topic to topic and leave the difficulty just where it was at first. But nobody who knew him intimately could fail to be struck by the immense range of his erudition or to be charmed by the simplicity of his character."

Brownlee was singularly free from personal jealousy or vulgar ambition and if he was not, in the formal sense, a great teacher of statistical epidemiology, his writings and example have done, and will continue to do, great good. Many years ago, Dr Campbell Munro wrote: "Dr Brownlee is a man of high intellectual endowments, of great breadth of view, of brilliant scientific attainments—a man who is certain to attain a high position in the public health speciality. He is a man of high moral purpose and elevation of character, and, with all his attainments, of singular modesty and simplicity." That might fairly stand for Brownlee's epitaph.

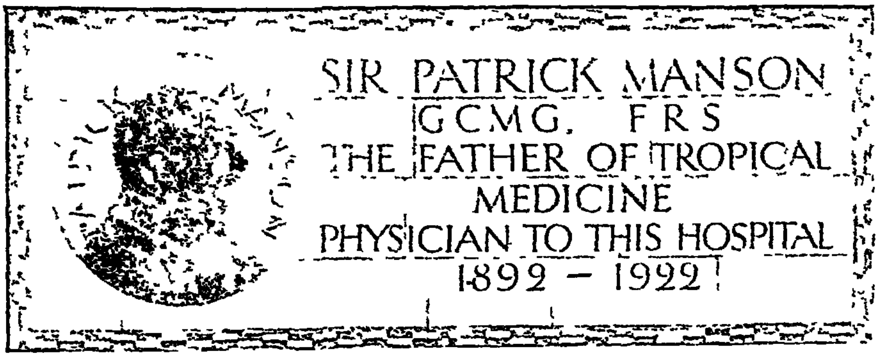
CORRADO DONATO DA FANO, M.D. Pav., F.L.S., F.R.M.S.

Dr C. D. Da Fano died suddenly at his home in Campden Hill at the age of 47 on March 11th, hardly more than a year after the death of his old teacher Camillo Golgi. Dr Da Fano was an Italian by birth and education who had lived and worked in this country only since the war, having been appointed as lecturer in histology at King's College, Dr A C **ROXBURGH** said that the comparison between sunlight and artificial light was vitiated because the latter had to be given in a relatively stuffy atmosphere He adduced, in support of the action of light being non-specific, figures showing how similar its results had been in tuberculous, non-tuberculous febrile, and non-febrile batches of patients Referring to its dangers, he related how one patient with lupus and another with sarcoids had developed phthisis after carbon arc treatment He had abandoned it for the treatment of dermatitis seborrhœica and had found that psoriasis cleared up better with chrysarobin ointment

Mr H J **CARDEW** corroborated Dr Sequeira's account of the good results obtained from the carbon arc given as a general bath in the treatment of keratitis, conjunctivitis, and other eye complaints

UNVEILING OF MEMORIAL PLAQUE TO THE LATE SIR PATRICK MANSON BY THE MINISTER OF HEALTH.

AN appropriate and sympathetic ceremony took place on March 15th at the Albert Dock Hospital, London The Minister of Health unveiled a memorial plaque to the late Sir Patrick Manson, the Father of Tropical Medicine, in the very ward in which, with the efficient aid of the Seamen's Hospital Society, Manson had established the clinical teaching of tropical medicine some 28 years ago Sir Arthur Clarke, the chairman of the Seamen's Hospital Society, in introducing Mr Neville Chamberlain, referred to the close association between Manson the Chamberlain family, and this Society, and expressed the hope that this "family association" might continue Mr Chamberlain emphasised the bearing of the main discoveries of tropical medicine on the trend of medical science as a whole, and in doing so he showed himself to be familiar not only with the technical achievements, but with the personal attributes of Patrick Manson He compared the historic association of Manson and Ross with that of Darwin and Wallace Throughout his speech Mr Chamberlain gave indications that the Minister of Health is fully alive to the paramount importance of tropical medicine in the Empire's affairs Dr George C Low, the senior physician, in proposing a vote of thanks, laid special emphasis on the persistence of Manson, ably backed by Joseph Chamberlain, in face of official and professional opposition to his schemes Prof R T Leiper, F R S, in seconding this vote, paid a warm tribute to the personality of Sir Patrick Manson as portrayed in the recently published account of his life and to his genius in stimulating and encouraging research



MEDICINE AND THE LAW

THE HUME-SPRY CASE

AFTER 15 days hearing the action brought by Mr Frederick Hume-Spry against Dr Robert Percy Smith, of Queen Anne-street, and Dr A H Watson, of Salisbury, claiming damages for alleged negligence in certifying him insane, came to its only possible conclusion The jury stopped the case, intimating that their unanimous verdict must be for the defendant doctors, Mr Hume-Spry's counsel admitted that it was impossible for him to succeed; and Mr Justice McCardie, who had tried the case with notable patience and judgment, explained that the verdict of the jury completely vindicated all those upon whose characters Mr Hume-Spry had cast aspersions The documents in the case are being retained in the custody of the Court so that the Director of Public Prosecutions may consider whether or not he will institute criminal proceedings against Mr Hume-Spry for perjury or otherwise, it is perhaps unlikely, however, that a jury will be asked to fix a man of Mr Hume-Spry's mental instability with criminal responsibility

The issues involved in the recent action were unusually grave in their bearing upon members of the medical profession The plaintiff complained that, in certifying him, the doctors had relied upon his having a fixed delusion that his wife had committed misconduct with Dr Woods, medical superintendent of the Palmers Green Hospital, in which the plaintiff had been a Ministry of Pensions patient, and upon statements that he had tried to murder his wife and to commit suicide He said he had reasonable grounds for believing that his wife had been unfaithful, he denied the attempted murder and suicide, and he said these facts would have appeared if the doctors had made proper inquiries His counsel, speaking doubtless according to instructions, at first gave the impression that he definitely asserted Mrs Hume-Spry's infidelity, the learned judge, indeed, seemed to expect that counsel would specifically cross-examine the witnesses against whom the plaintiff had made these allegations, as to actual times and places where the suggested misconduct had occurred Later in the case it appeared that the plaintiff's counsel abandoned the assertion of misconduct and retired upon the safer position (untenable as the jury's verdict has established) that the conduct of the persons concerned was such that a sane man might reasonably have inferred misconduct It was the plaintiff's view that the officials and doctors of the Ministry of Pensions had conspired wrongfully to send him to the asylum For this suggestion, Mr Justice McCardie declared emphatically, there was not the slightest foundation

The proceedings will inevitably prompt the question how much longer a medical practitioner is to be exposed to attack for discharging duties which the Lunacy Law lays upon him, but which he cannot legally be compelled to perform The Act of 1890 protects those who sign medical certificates of insanity if they have acted in good faith and with reasonable care The Royal Commission set up after the Harnett case, recommended that the *onus* of proving good faith and reasonable care should be shifted, and that instead of the doctor having to discharge it, the complaining patient should be obliged to prove said or done to correct some of the exaggerated statements made

Ultra-violet Light for Children

Dr H M **Oddy** pointed out the difference between the action of ultra-violet light on the skin of adults and infants respectively Although an infant's skin was thinner, an erythema was much harder to produce in it than in that of an adult The danger of overdose was therefore increased, for children could not describe their symptoms The signs were increased irritability and restlessness, disturbed sleep, a persistent loss of weight, digestive troubles, and a loss of appetite Except in tuberculosis, better results were obtained with the mercury-vapour lamp than with the carbon arc His impression was that the tungsten lamp was not of much use to children except in general baths Treatment should not be continued too long; 12 to 20 applications should be followed by a month's rest The action of light on the cholesterol, calcium and phosphorus in the blood was known, and there might be yet other substances on which light acted to produce its therapeutic results Gastric juice, for instance, had its acidity lessened by light baths Turning to the clinical uses of light, he remarked that it should be employed in rickets as an adjunct to cod-liver oil In tuberculous peritonitis and glandular tuberculosis light was counter-indicated by active disease of the lungs, otherwise it might be used in graduated doses It gave better results in tuberculosis of the bones and joints Light should never replace other treatment in surgical tuberculosis, but should be used in conjunction with it In pregnancy and lactation, especially when the milk flow fell off, light was very useful It acted like a charm in restless cases of malnutrition and marasmus, but might do harm to a very severe case Older children of the "hypotonic" type benefited much, failures, especially with out-patients, were generally due to overdose or bad regulation Light therapy was indicated in post-febrile and post-operative debility and depression, muscular paralysis, asthma, late whooping-cough, and anæmia where hæmoglobin was low, but was counter-indicated in leukæmia

The Physiological Basis of Light Treatment

Dr A **Eidinow** dealt with the scientific and biological aspects of light treatment, and related experiments undertaken to show its action on the bactericidal power of the blood Irradiated skin did not differ from ordinary skin in its bactericidal value, and the penetrative power of the rays was very small, therefore the result could not depend on direct action on the skin or on the blood or blood-cells The ultra-violet rays were bactericidal, but bacteria in blood or serum when exposed to the rays, cool, were entirely unaffected The solution of the problem seemed to lie in the proved fact that an erythema dose of light will produce a fixed leucocytosis beneath the skin, and to the activation and absorption of the ergostearol present in skin and sweat glands It had been shown that this ergostearol was allied with the cholesterol, and that when irradiated it was the potent factor in preventing rickets The skin rapidly became immune to ultra-violet rays, and remained so for 14 days until the desquamation was over and new skin had developed There was a definite optimum area for exposure if the maximum bactericidal effect were to be obtained, this was one-sixth of the total surface area There was no need for large, massive exposures This point needed clinical investigation and might revolutionise the technique of exposures Many bad results might be due to the fact that the patient's skin was immune to light, and so he was not getting irradiation at all The dosage depended much more on the surface area of skin exposed than on the quantity of light The most important counter-indication was the extent to which the disease had progressed Very serious results might follow large exposure in cases where the blood was impoverished, as in septicæmia

Light in Surgical Tuberculosis

Sir **Henry Gauvain** pointed out that, although the title of the discussion was "ultra-violet" rays, very little work had been done on the use of pure ultra-violet rays, and in actual treatment no one had cut off the infra-red and visible rays, except for diagnostic purposes, as in ringworm. He was sure that for surgical tuberculosis real sunlight was the best and in sunlight the ultra-violet rays only constituted 1 per cent The value of the artificial methods—carbon arc and mercury-vapour lamp—diminished as their ultra-violet ray power increased Clinical experience did not support the view that the good effects of the treatment are due to the ultra-violet waves Other radiations must have either some good effect or else the power of intensifying, diluting, or modifying the ultra-violet The visible rays certainly had much greater penetrative power In surgical tuberculosis light was not specific and must be regarded merely as an aid—though a very valuable aid—to other forms of treatment It had been shown that the increase in basal metabolism during exposure to sunlight was not due to the rays but to the cold air The value of light largely depended on the patient's general reaction, which was made up of many constituents One was pigmentation, and there was no doubt that the majority of pigmenters did very much better than the majority of non-pigmenters Healing lesions healed more quickly under light treatment though progressive lesions did not benefit The healing of sinuses was hastened, often with very little scarring and sequestra might be painlessly extruded He did not entirely agree with Dr Eidinow that there could be no direct action of light on the bacteria in lupus The nodules might be more easily permeable by light than ordinary skin A brisk local dose from the mercury-vapour lamp would produce little blebs wherever there were nodules, when the rest of the skin was not blistered. These blebs might assist in healing

General Discussion

Dr J H **Sequeira** agreed that the visible rays were of value The general treatment of the body by light had healed lupus without any local measures whatever but in no case was it wise to rely entirely upon general irradiation of the body It had been shown that no change was produced in basal metabolism solely by general light baths, nor did these baths prevent the acute specific fevers In post-febrile debility, however, they were of great value He had seen very good results with lupus in patients who did not pigment The hæmobactericidal reaction was a test requiring the utmost delicacy and experience in observation, and was not likely to be of much practical use The area to be exposed was a problem requiring the most careful investigation He had been very disappointed with the clinical results in cases treated by the piecemeal methods Light treatment was of very great value in some chronic eye affections especially phlyctenular conjunctivitis, corneal ulceration, and some cases of tuberculous irido-cyclitis.

Dr **Katherine Gamgee** said that it was the children under four or five whose reaction was so different from that of adults Older children than this gave a more or less adult reaction She thought in rickets the time factor was important Light sometimes worked amazingly where cod-liver oil failed, and was especially good for nervous children, and for nocturnal enuresis in particular. It was valuable in convalescence, and to prepare children for nose and throat operations In anterior poliomyelitis, unless the child were submitted very early, it was disappointing A small area of skin only should be dosed, and the place constantly varied The body cells easily became stale, quite apart from pigmentation There was an optimum for each case She recommended courses of about six weeks, followed by a rest and another course Light was a highly stimulating drug, of which the body cells soon became tired

UNIVERSITY OF ST ANDREWS—An anonymous nor has given £100,000 to the University, out of which e sum of £40,000 is to be set aside to found residential holarships.

NAVAL MEDICAL COMPASSIONATE FUND—A meeting the subscribers of this Fund will be held at 11 30 A.M. on pril 21st, at the Medical Department of the Navy, Queen ne's Chambers, Tothill-street, Westminster, S W 1, to ect six Directors of the Fund

ROYAL NAVY MEDICAL CLUB—The annual dinner ill take place at the Trocadero Restaurant, Piccadilly rcus, W 1, on Thursday, April 21st, at 7 30 P.M., for 8 P.M. embers who wish to be present are asked to inform the on. Secretary of the Club, Queen Anne's Chambers, Tothill-reet, London, S W 1, not later than seven clear days before at date

CONFERENCE ON MATERNITY AND INFANT WELFARE der the auspices of the Central Council for Infant and Child elfare, and in connexion with the National Baby Week lebrations, a conference will be held in the hall of the tish Medical Association, Tavistock-square London, n July 5th to 7th, under the presidency of Mr. Neville amberlain, Minister of Health

NORTH-WESTERN TUBERCULOSIS SOCIETY—At the st meeting of this society, to be held on Thursday, rch 31st, at 3 15 P.M., at the Public Health Laboratory, rk place, Oxford-road, Manchester, Prof Lyle Cummins will ad a paper on the Bearing of Recent Laboratory Research Clinical Conceptions in Tuberculosis The meeting will open and the attendance of medical practitioners is nted.

SOCIETY FOR THE PROVISION OF BIRTH CONTROL NICS.—On Wednesday, March 30th, at 5 30 P.M., Lord wson will take the chair at a meeting in aid of this ciety to be held by permission of Capt Gerard Leigh at , Grosvenor-street, London, W 1 The speakers will be Margaret Sanger (president of the American Birth ntrol League) and Mr. Harold Cox

CLEAN AIR WEEK—Smethwick in Staffordshire ld a "Clean Air Week" from March 14th to 19th, during ich period an effort was made to keep the atmosphere free m smoke The campaign included demonstrations, tures, and other forms of propaganda in which the rporation Gas and Health Departments, and most of e large industrial firms in the district coöperated

IRISH MEDICAL SCHOOLS' AND GRADUATES' ASSO-TION—The objects of the Association are (1) to support every legitimate way efforts made to improve the status the profession at large, especially of those holding Irish grees or diplomas in medicine, (2) to promote social ercourse among those holding medical qualifications tained in Ireland and others who have studied at an Irish hool of medicine The annual meeting and festival nner takes place in London on St Patrick's Day, and was d this year on Thursday, March 17th, at the Savoy Hotel, ndon, the President, Sir William de Courcy Wheeler, ng in the chair There was a good attendance, many ies being present at what proved a very enjoyable ction There were only two toasts, "The Guests" d "The Prosperity of the Association." The toast of The Guests" was proposed in a witty and unconventional eech by Colonel G A. Moore, A.M S (retd), who inter-rsed a cordial welcome of the guests with amusing h stories Vice-Admiral Sir Frederick Field, Sir Squire gge, and Dr Bertram Watson returned thanks for the sts. Vice-Admiral Field held closely the attention of company with a description of the happiness and sperity that followed health developments in all ts of the world He spoke of his experiences when command of the Special Service Squadron during the ld cruise of 1923–24, and instanced the vast benefits ich had been received by populations in the ultimate ions of the Empire through the discoveries of medicine through the faithful ministrations of doctors The st of the Association was proposed by Dr Kenneth Fraser, o in coupling it with the name of the Chairman, spoke Sir William Wheeler's valuable work in surgery and his tion both in public and private Sir William Wheeler, eply, pointed out, with special reference to the position the Irish Free State, that it was the great object of the sident, fierce fighter as he had been in the past, to main- the conditions of peace and good feeling which were ad leading to prosperity At the request of the company onel Moore continued his selection of Irish stories, which various intervals in the proceedings were interspersed h songs from Miss Veronica Mansfield and Mr Richard tson, accompanied by Miss Nellie McCartney The honorary secretary of the Association, responsible the dinner, was Dr F R Holmes Meyrick

UNIVERSITY OF DUBLIN—Amongst the recipients of honorary degrees at the Summer Commencements on June 28th will be Sir Humphry Rolleston and Prof Harvey Cushing

HARVEIAN SOCIETY OF LONDON—An ordinary meeting of this society will be held in the Paddington Town Hall on Thursday, April 7th, at 8 30 P.M., when a discussion on the treatment of Graves's disease will be opened by Mr T P Dunhill, to be followed by Dr C M Wilson and others.

UNIVERSITY OF DURHAM—It is proposed that the honorary degree of Doctor of Civil Law shall be conferred at the June Convocation upon Sir James Berry, consulting surgeon to the Royal Free Hospital, London, and President of the Royal Society of Medicine

UNIVERSITY COLLEGE HOSPITAL—At the annual general meeting on March 24th it was stated that nearly 10,000 visits were paid to mothers in their own homes by the health visitors from the Infant Welfare Department For the sum of £20,000 a building at the back of the Obstetric Hospital could be converted into headquarters for the Centre Out-patients' attendances at the hospital approached 250,000 during the year, and the number of in-patients increased by about 600

HOSPITAL OF ST CROSS, RUGBY—In memory of her husband Mrs Arthur James is presenting to this hospital a complete out-patients' department, with minor operating, dental, and recovery rooms The block which is to be built forthwith will be arranged to allow of extension

A SHEFFIELD HOSPITAL AREA.—A conference of local hospital authorities has decided in favour of a system of coöperation and coördination, with Sheffield as the pivot of the scheme The area concerned includes Barnsley, Mexborough, Doncaster, Denaby Rotherham, Worksop, Retford, Bakewell, and Chesterfield

MEDICAL STUDENTS VISIT A SPA—Students from the University of Birmingham accompanied by Prof Douglas Stanley and other members of the staff, went to Bath on March 19th and visited the bathing establishment and Royal Mineral Water Hospital A short address was given by Dr A Gordon Watson, and cases were demonstrated by Dr Rupert Waterhouse, Dr R G Gordon, Dr James Lindsay, Dr H Clulow Nixon, and Dr J Litt

MANGANESE POISONING—At Stroud County Court on March 13th Judge Alan Macpherson recorded agreements for the payment of lump sums of £800 and £750 respectively, as compensation to two men suffering from manganese poisoning contracted whilst at work for a paint and varnish manufacturer

MILK PASTEURISATION AND HUMANE SLAUGHTER—On March 17th a large party of veterinarians and medical men set out in charabancs from the Royal College of Veterinary Science and visited the pasteurising plant of Messrs Curtis Bros and Dumbrill, at Valley Farm Dairy, Streatham The arrangements were made by Prof F T Hobday, and amongst those present were Sir D'Arcy Power, Major-General Sir John Moore, Prof G H Wooldridge, Dr E G Gibbs-Smith, and Lieut-Colonel T Dunlop Young After being shown the working of the pasteurising plant, which is a model of efficiency and is always open to public inspection, the party was entertained to tea by Messrs Curtis Bros and Dumbrill. Mr P B Tustin, in welcoming the guests, asked for their interest in the Young Farmers' Club Movement inaugurated by United Dairies to teach the sons and daughters of farmers kindness to animals, clean and economical milk production, and the proper feeding and judging of dairy animals Prof Hobday, Sir John Moore, Prof Wooldridge, and Colonel Young expressed their satisfaction with the conditions of work at the Valley Farm Dairy, and thanked Mr Tustin for the careful explanation of methods which had been given After leaving the dairy, the party visited a local butcher's shop where Mr Weinberg gave a demonstration of his method of slaughtering cattle for Jewish consumption According to Jewish law the animal must be killed by cutting the throat, only one cut being made, and no previous stunning being allowed This involves extension of the head on the neck, and in killing bullocks it is usual to tether their legs, throw the animals heavily to the ground, and wrench back their heads A horn is often broken off during this procedure Mr Weinberg's apparatus is designed to obviate brutality It consists of a wooden cage pivoted on a frame, the cage, when the animal has entered, is suddenly reversed so that the bullock is now resting on its back. At this stage it is probably confused and dizzy and the neck is fully exposed to the knife, no wrenching being necessary This method was satisfactorily demonstrated and was generally considered more humane than those in use at present The limitations of the Streatham slaughter-yard unfortunately made it impossible to withdraw the carcass yard unfortunately made it impossible to withdraw the carcass expeditiously, so that the time occupied in the whole performance could not be estimated exactly bad faith and negligence The distinction is not revolutionary Another suggestion was made by Lord Sandhurst in the House of Lords debate on Earl Russell's motion (on Feb 24th)—namely, that the damages recoverable for wrongful certification should be limited to the period of one month's detention, the fresh report at the end of the month being deemed to interpose a fresh responsibility. This would save the award of colossal damages as in the Harnett case (which is still before the House of Lords on legal questions concerning the effect of the Statute of Limitations and the Public Authorities Protection Act), but it would not have saved Dr Smith or Dr Watson from the annovance and expense of defending themselves against Mr Hume-Spry. The proper remedy is to realise that the reception of a lunatic takes place upon the direction of what the Act calls a "judicial authority" It is the magistrate's order, not merely the doctor's opinion, which counts The authority of the magistrate was interposed by Parliament in days when the public, alarmed by the stories of Victorian novelists, believed madhouses to be full of sane persons illegally and improperly detained The recent Royal Commission, Earl Russell has said found no case in which a man could be said to have been wrongfully certified The magistrate is, under the modern administration of the Lunacy Law, no longer necessary as the protector of the liberty of the subject But if he is retained, he must take the responsibility for his judicial actions And the public must decide whether it wishes to allow lunatics to wander at large without restraint, or whether it will support the medical profession, whose uncomfortable duty it is to contribute an expert opinion upon the question of restraint

Dr Percy Smith and Dr A. H Watson are both members of the Medical Defence Union, and the counsel appearing for them were instructed by Messrs Hempsons, the solicitors to the Union

Medical News.

University of Oxford —Under a bequest to the University made by the late Dr Gustave Isidore Schorstein, assistant physician to the London Hospital, a Schorstein Research Fellowship in Medical Science is to be established and it is probable that an election will be made during the Summer Term The proposed conditions were published in the *Oxford University Gazette* of March 16th

Dr Arthur Duncan Gardner, who is engaged in research in the department of pathology and bacteriology, and is bacteriologist in charge of the standards department of the Medical Research Council, has been elected to a special supernumerary Fellowship at University College

University of London Course in Mental Deficiency —A course of lectures for medical practitioners is to be held at the University of London, under the auspices of the Central Association for Mental Welfare, from May 23rd to 28th The lecturers include Dr A F Tredgold, Dr F C Shrubsall, Prof Cyril Burt, D Sc, and Dr W Norwood East Particulars may be had from Miss Evelyn Fox, c/o the University Extension Department, Imperial Institute-road, S W 7

Examiners in Nursing —At a recent meeting of the Senate the following were appointed examiners for the Diploma in Nursing —(1) Scientific Basis and General Principles of Nursing Miss T J Dillon, Miss W A Leyshon, Prof R H A. Plimmer, Prof C K Tinkler, Mr H P Gilding, Miss Catherine Lewis, M S, Dr W R Spurrell, Prof William Wright, F R C S, Prof W Bulloch, M D, F R S, Dr R G Canti, Dr C E Dukes, Dr Joan Ross, Dr J. A H Brincker, Dr W W Jameson, Dr Charles Porter, Dr Ruth E Proctor, Mr F A P. Aveling, D D, Prof Beatrice Edgell, Mr C J Flügel, and Dr J A Hadfield, (2) History of Nursing to 1919 and Nursing Ethics Miss Dorothy Coode, Miss Gertrude Cowlin, Mrs Lucy Ridgly Seymer, and Miss Frances Sheldon (3) General Nursing: Miss M A Gullan, Dr C E Lakin, Miss E McManus, and Miss G M Simms, (4) Obstetric and Gynæcological Nursing Lady Barrett, M S, Mr A [illegible] Bourne, F R C S, and Miss N Newall; (5) Nursing of Children Miss E Cockeram, Miss A. M Coulton, and Miss Alice M Machell, (6) Mental Nursing Miss E L. Macaulay, Dr W. F Menzies, Prof G M Robertson, P.R C P Edin, and Miss M M Thorburn, (7) Fever Nursing and Epidemiology Miss J H Balsillie, Dr F F. Caiger, Dr Joseph Cates, and Miss L F Pearce, (8) Elementary Economics, Sociology and Hygiene : Dr Joseph Cates, Mrs E A Warren, and Miss H Weir, (9) Hospital Administration Sir Cooper Perry, M D, Miss Lloyd Still, Mr E W Morris, and Miss E M Musson, (10) Methods of Teaching Prof C L Burt and Miss K L Johnston

University of Manchester —At recent examinations the following candidates satisfied the examiners —

Diploma in Public Health —N S Craig and T N Fisher

Diploma in Psychological Medicine (Part I) —Mary C Luff.

Royal Institute of Public Health —At the Whitsuntide Congress to be held at Ghent, Belgium, from June 1st to 6th, a special section will be devoted to industrial hygiene, and there will be discussions on industrial cancer, rheumatism, and temperature and humidity in industrial health Dr A Vernon Davies, M P, will be glad to hear from medical men and employers who would like to take part, communications may be addressed to him at the House of Commons, London, S W 1

Fellowship of Medicine and Post-Graduate Medical Association —On Thursday, March 31st, at 5 P M, Dr C T W Hirsch will lecture and give a demonstration on Emergencies in Anæsthetics at the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square On the same afternoon at 3 P M Mr H L Attwater will give a clinical surgical demonstration at the All Saints' Hospital, Vauxhall Bridge-road, S W Both lecture and demonstrations will be free to members of the medical profession From March 28th to April 9th the Queen's Hospital for Children will hold a special course, a programme occupying the whole day has been arranged and the chief feature of instruction at this hospital is the showing of cases rather than formal lectures Also beginning on March 28th and continuing for two weeks, the Royal Eye Hospital staff will undertake a series of afternoon demonstrations on the Diagnosis and Treatment of Diseases of the Eye. The Fellowship can arrange practical courses in obstetrics and anæsthetics, and can also make arrangements for clinical assistantships in gynæcology Copies of all syllabuses and of the *Post-Graduate Medical Journal* are obtainable from the Secretary of the Fellowship at 1, Wimpole-street, London, W 1

The late Dr C E Humphreys —The death has taken place of Dr Charles Evan Humphreys, of Macifod, near Welshpool, coroner for North Montgomeryshire, and medical officer of health and school medical officer for the county After studying at the London Hospital, he qualified L S A in 1883 and M R C S in 1884, taking the D P H in 1911 Formerly in private practice at Welshpool Dr. Humphreys gave this up nearly 20 years ago to become medical officer of health He effected great improvements in the health service of the county, more especially in the provision of district nurses and the medical inspection of schools During the war he served in the R A M C (with the rank of Lieut -Colonel) and acted as sanitary officer of the 68th Welsh Division and specialist sanitary officer at the Ripon Reserve Centre of the Northern Command His two sons were also in the army

Sussex Hospitals —The Royal Alexandra Hospital for Sick Children, Brighton, admitted 1055 patients last year and 587 operations were performed At the end of the year the general account was overdrawn by about £320, but money is being collected to build a new wing in memory of Queen Alexandra —The New Sussex Hospital for Women and Children dealt with 491 in-patients and 13,403 out-patient attendances during the year Income slightly exceeded expenditure, and the construction of a new wing, which will cost £10,000, is in progress —The household box scheme has proved the salvation of Worthing Hospital, and £1432 was collected by means of it There was a small deficit on the year's working, and the governors had to draw on capital to pay for extensions —No less than 3931 women received attention from the Sussex Maternity and Women's Hospital at Brighton during 1926, 1100 being attended in their own homes, 1173 at the antenatal clinic, 702 in the out-patients' department, 71 in wards at the Hove branch, and 879 in the wards at Brighton, where 333 children were born The governors consider that the hospital has outgrown its strength and are proceeding with enlargement —As we have already stated, the Royal Sussex County Hospital is this year celebrating its centenary, and an appeal for £100,000 is being made to enable the governors to carry out large alterations —A scheme has been started for increasing accommodation at Petworth Hospital at a cost of £3000 Lord Woolavington is giving £1000 on condition that the extension is at once begun

Plymouth, South Devon and East Cornwall Hospital —Cas H S
Poplar Hospital for Accidents, East India Dock road, Poplar, E —Second Res O £175
Reading, Royal Berkshire Hospital —H S £150
Rochford Hospital —Asst Res M O £175
Samaritan Free Hospital for Women, Marylebone road, N W —Hon. Surg to Out patients
Sheffield Royal Hospital —Sen Cas O £150
Sheffield Royal Infirmary —H S At rate of £80
St John's Hospital, Lewisham, S E —Res Cas O At rate of £100
University of London, South Kensington, S W —Chair of Anatomy £1000
York County Hospital —H P £150

The Chief Inspector of Factories announces a vacancy for a Certifying Factory Surgeon at Porlock (Somerset)

The Secretary of State for the Home Department gives notice of a vacancy for a Medical Referee under the Workmen's Compensation Act, for the Districts of the Bangor, Conway, Llandudno and Colwyn Bay and Llanrwst County Courts (Circuit No 29) Applications should reach the Private Secretary, Home Office, not later than April 6th

Births, Marriages, and Deaths.

BIRTHS

LKINGTON —On Feb 23rd at Bruton, Somerset to Kathleen wife of Dr Guy W Elkington—a son

IGGINS —On March 15th, at a nursing home the wife of Lionel G Higgins, F R C S of Linkwood, Woking of a son

ANTON —On March 17th, at Bovington Camp, Wareham Dorset, the wife of Captain D F Panton, R A M C, *of a son*

MARRIAGES

AYDON—RICHMOND —On March 17th, at St Peter's Church, Cranley gardens, Leonard John Haydon, M R C S, L R C P, to Susan Eleanor Richmond, youngest daughter of Mr and Mrs D C Richmond, of Cornwall-gardens, S W

DEATHS

URD —On the 21st inst, at Mornington, Richmond-road, Malvern Link, Cyril Prichard Burd, M R C S, L R C P, aged 51 years

AY —On March 17th, suddenly, at Caunce street, Blackpool Percy Howard Day, L R C P, L R C S Edin., aged 70

ALMER —On March 15th after two days' illness, (pneumonia following influenza), at Marine avenue, Hove, Harry Palmer, M R C S, L R C P Lond

B —A fee of 7s 6d is charged for the insertion of Notices of Births, Marriages and Deaths

RICE IN SHREDDED SUET —At Stoke-on-Trent on arch 18th the Potteries stipendiary magistrate dismissed e cases against four firms summoned for selling shredded et adulterated with an excessive quantity of ground rice HE LANCET, Feb 12th, p 372) The prosecution had leged that 15 per cent of ground rice was ample, and that samples taken from the defendants' shops this quantity d been exceeded The magistrate held that 15 per cent s sufficiently high, but suggested that in view of manufac- ring difficulties food inspectors should not trouble about atively small percentages over that standard

SPINNER'S CANCER —Dr J C Beckitt, medical officer of health for Leigh, Lancashire, stated on March 18th, in a lecture at Leigh, that since the war 539 cases of spinners' cancer had been traced in Lancashire and Yorkshire alone Between 1911 and 1920, 486 males had died of cancer of the scrotum, and of these 100 were operative cotton-spinners, whilst the remainder included 52 general labourers, 41 chimney sweeps, 11 dock labourers, 10 chemical workers, 11 coal miners and 11 gasworks hands Deaths were thus more prevalent among cotton-spinners than any other workers The disease usually showed itself between the ages of 35 and 55, and not until the person had been employed in the mule room for ten years at least Change of occupation was no guarantee that it would not occur Indeed the malignant growth might not appear until a considerable time after employment in a mule room had ceased The greater the amount of oil soaking into the clothing the greater was the danger Cleanliness was all essential, and Dr Beckitt recommended the wearing of protective clothing in the form of an apron impervious to oil

Notes, Comments, and Abstracts.

PYELOGRAPHY AND ITS VALUE IN DIAGNOSIS

Being an Address delivered before the Brighton and Sussex Medico-Chirurgical Society

By F E Fielden, F R C S Edin, M R C S Eng,

ASSISTANT SURGEON, HOVE GENERAL HOSPITAL AND ROYAL ALEXANDRA HOSPITAL FOR CHILDREN, SENIOR ASSISTANT, UROLOGICAL DEPARTMENT, MIDDLESEX HOSPITAL

PYELOGRAPHY is the radiographic examination of a solution opaque to X rays, which has been introduced into the renal pelvis and ureter I know of no branch of surgery that possesses more accurate means of diagnosis than urology, and, of these, I believe pyelography to be one of the most important

Abdominal pain, whether acute or chronic, may be due to some pathological condition of the upper urinary tract, although urinary symptoms and gross changes in the urine are absent On the other hand certain cases present urinary symptoms although the causative lesion is to be found outside the urinary tract.

It is in such cases of obscure ætiology that pyelography is of special assistance, and whenever there is abdominal pain of doubtful origin pyelography should be done, unless a diagnosis can be established by other less elaborate and special means

It was in 1905 that Hurry Fenwick introduced the opaque ureteric bougie which preceded the use of a solution for rendering the outline of the pelvis and ureter visible in radiograms The value of the method was slow to be appreciated, and at first received but scant attention, and even now, although pyelography has received wide recognition, it is not, I think, employed often enough nor is its value sufficiently understood It should not be looked on as an infallible method of arriving at a correct diagnosis, but, as with every other method of urological investigation, the diagnosis should be reached only after careful consideration of both the radiographic and the clinical picture In certain instances, however, pyelography may be the *only* means, short of an exploratory operation, of solving a clinical problem

Interpretation of the Pyelogram

In cystoscopy the greatest difficulty lies in the interpretation of the picture, and the same is true in pyelography It is, therefore, essential to become thoroughly familiar with the normal pyelogram, for by so doing we shall more readily appreciate deviations from normal and consequently be in a position to state with confidence that a given pyelogram represents a pathological condition of the pelvis or kidney This is very important For example a man presents himself with a history of hæmaturia, radiography and bacteriological examination of the urine do not throw any light on the cause, and cystoscopy fails to reveal any lesion in the bladder or ureteric orifices Not infrequently, in such a case, the patient is told to come up again when he is bleeding so that the operator may see which kidney is giving rise to the hæmorrhage In my opinion this enforces an unnecessary delay, which may be greatly jeopardising the patient's chance of recovery There should be no waiting, a right- and left-sided pyelogram should be taken so that many of the causes of hæmaturia of renal origin can be at least eliminated, and the cause of the symptoms may, perhaps, be dramatically revealed

In reading a pyelogram the following points should be borne in mind The normal pelvis is trumpet-shaped, and is set almost vertically on the upper end of the ureter, the calyces project from it laterally, some of them in an antero-posterior direction The normal major calyx divides into minor calyces, which have a cup-shaped extremity in the hollow of which lies the pyramid Calyces, seen on end, appear as round, darker patches, and should not be mistaken for calculi Normally the catheter passes from the ureter to the pelvis and then into the upper calyx, the expansion of the ureter into the renal pelvis is a gradual transition, and there should be no line of demarcation It should be remembered that the right pelvis lies at a slightly lower level than the left, when the left is lower than the right there is some pathological reason for it, when either lies below the level of the third lumbar vertebra, the condition is abnormal

In addition to the ordinary anteroposterior view of the kidney, a lateral picture may be taken; it will then be noticed that in this pyelogram the kidney pelvis lies in the shadow of the second and third lumbar vertebræ, and the calyces are spread out laterally from the pelvis The pelvis appears

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning

THURSDAY —10 A M, Dr Stewart Neurological Department 12 noon, Mr Simmonds Demonstration of Fractures 3 P M, Sir H Simson Gynæcological Ward

FRIDAY —11 A M, Dr Pritchard Modern Methods in Medicine 2 P M, Mr Sinclair Surgical Out patients

SATURDAY —9 30 A M, Dr Burnford Bacterial Therapy 10 A M, Dr Owen Medical Diseases of Children

Daily —10 A M to 5 P M, Operations, Medical, Surgical, Special, Out-patient Departments (Saturdays, 10 A M to 1 P M)

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole street, W

MONDAY, March 28th, to SATURDAY, April 2nd —FELLOWSHIP OF MEDICINE Special lecture demonstration at the Medical Society, 11, Chandos-street, Cavendish-square, W, at 5 P M, on Thurs Dr Hirsch Emergencies in Anæsthetics Open to all members of the medical profession, without fee —ALL SAINTS' HOSPITAL, Vauxhall Bridge-road, S W Thurs, 3 P M, Mr H L Attwater Special demonstration (genito urinary), free to members of the medical profession —LONDON TEMPERANCE HOSPITAL, Hampstead road, N W 4 30 to 6 P M, General Practitioners course Medicine, Surgery, and the Specialties —QUEEN'S HOSPITAL FOR CHILDREN, Hackney road, Bethnal Green, E All day course the chief feature of which will be the showing of cases —ROYAL EYE HOSPITAL, St George's Circus, Southwark, S E Afternoon demonstrations on the diagnosis and treatment of diseases of the eye —ROYAL NATIONAL ORTHOPÆDIC HOSPITAL, 234, Great Portland-street, W Comprehensive course Morning and afternoon sessions including Saturday

Further information from the Secretary

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N

MONDAY March 28th —10 A M, Surgical Clinic 2 P M, Medical Cases in the Wards 2 30 P M to 5 P M Medical, Surgical, and Gynæcological Clinics Operations

TUESDAY —2 30 P M to 5 P M, Medical, Surgical, Throat, Nose, and Ear Clinics Operations

WEDNESDAY —2 30 P M to 5 P M, Medical, Skin, and Eye Clinics Operations

THURSDAY —11 30 A M Dental Clinic 2 30 P M to 5 P M, Medical Surgical, and Ear, Nose and Throat Clinics Operations

FRIDAY —10 30 A M, Throat, Nose, and Ear Clinics 2 30 P M to 5 P M Surgical, Medical, and Children's Diseases Clinics Operations

On TUESDAY, March 29th, and THURSDAY, March 31st, at 2 30 P M, there will be special demonstrations of Medical and Surgical Cases by Mr W E Tanner and Dr A J Whiting respectively

Also on FRIDAY, April 1st, at 4 30 P M, Dr L R Yealland will demonstrate on Selected Cases of Nerve Disease

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn road, W C

FRIDAY, April 1st —4 P M, Dr Dan McKenzie Diathermy in the Treatment of Cancer in the Pharynx

HOSPITAL FOR SICK CHILDREN, Great Ormond street, W C

THURSDAY, March 31st —4 P M, Mr Tyrrell Gray Abdominal Pain

LONDON SCHOOL OF DERMATOLOGY, St John's Hospital, 49, Leicester square, W C

TUESDAY, March 29th —5 P M, Dr G B Dowling Scleroderma Neurofibromatosis

PEOPLE'S LEAGUE OF HEALTH (Sims Woodhead Health Lectures)

MONDAY, March 28th —6 P M (at the Medical Society of London 11, Chandos street, W), Sir Robert Armstrong Jones Brain and Nervous Systems

ANCOATS HOSPITAL, POST GRADUATE LECTURES, Mill-street, Manchester.

THURSDAY, March 31st —4 15 P M, Dr W J S Reid Tabes Dorsalis

MANCHESTER ROYAL INFIRMARY POST GRADUATE LECTURES

TUESDAY, March 29th —4 15 P M, Mr H H Rayner Pulmonary Embolism

FRIDAY, April 1st —4 15 P M, Mr C Roberts Demonstration of Surgical Cases

ST MARGARET'S HOSPITAL FOR WOMEN, Acomb street, Whitworth Park, Manchester

WEDNESDAY, March 30th —12 noon, Mr A C Magian Demonstration Operation on Ovarian Grafting

Appointments.

GILMORE, E R W, M B, Ch B Manch D P H Lond and Manch D T M Liverp, has been appointed Assistant School Medical Officer to Education Committee, City of Salford

READER, N L M, M D Lond, F R C S Eng, Surgeon to the Barry Accident and Surgical Hospital

THE SALE OF MEAT.

[illegible]ENCE AT ROYAL SANITARY INSTITUTE

[illegible]NCE on the Public Health (Meat) Regulations [illegible] came into force on April 1st, 1925, was held at the Royal Sanitary Institute Alderman W [illegible] (City of London) occupied the chair.

[illegible] **Brennan de Vine** (Veterinary Superintendent, [illegible]) said that lack of uniformity in carrying out [illegible]ions in the different administrative areas had [illegible]derable dissatisfaction in the meat trade The [illegible] of meat should include poultry, rabbits, cooked [illegible]ed meat The adhesive surfaces presented by [illegible] rabbits and butter caused dirt to stick to them more [illegible] butchers' meat often sold from the same shop, this [illegible] treatment caused adverse comment Cooked meat [illegible] removed from a tin were a greater source of danger [illegible] poisoning than butchers meat.

[illegible] requirement of giving notice of slaughter saved the [illegible] of the meat inspector Illicit slaughtering was, how[illegible] going on in places other than recognised slaughter[illegible], and local authorities and magistrates should be [illegible] by the Ministry of Health that this was a serious [illegible]. Notification of disease in slaughtered animals was [illegible] evaded by cottagers, small-holders, and farmers [illegible] slaughtered a few animals at intervals The [illegible] requiring that a slaughter-house should be used [illegible] slaughtering had enabled the Birmingham [illegible] to improve conditions in a number of places used [illegible] day in the week as a slaughter-house, on another as [illegible]-house, and for the rest of the week as a lumber store. [illegible] power to prohibit the use of a slaughter-house for gutting and tripe-cleaning, in order to prevent the fecal [illegible] of carcasses, was in itself worth the whole of [illegible] entailed in carrying out the regulations Only [illegible] local authorities had been able to persuade their [illegible] to accept the system of marking every inspected [illegible], yet this was widely carried out on the continent.

[illegible] and shops should be required to provide glass [illegible], he had seen in Rotterdam meat stalls in which [illegible] meat was kept and exhibited behind glass Meat [illegible] should be licensed, to protect the meat all the time [illegible] storage-places should be registered so as to facilitate [illegible]. In Birmingham there was no meat hanging [illegible] a stall or shop, although it was recognised that a [illegible] authority had no power to compel the provision of [illegible] windows, the meat was kept behind glass in 90 per cent. [illegible] shops The efforts of local authorities to obtain [illegible] fronts had been nullified by Circular 604 which stated [illegible] not all butchers' shops need be so provided But all [illegible] who had studied the question from the economic [illegible]point kept their meat behind closed glass windows [illegible] prevented the meat losing its bloom when it had to [illegible] at a cheaper rate; the loss of weight by evaporation [illegible] was avoided and the meat kept longer In Birming[illegible] two firms, one with 50 branches the other with 40 [illegible], had provided fixed closed glass windows No loss [illegible] occurred when the practice of hanging up meat [illegible] shops was given up Circular 604 stated that where [illegible] to be kept near to an open window the general rule [illegible] be that it should be covered with clean muslin or other [illegible] material, but when a brisk trade is being carried [illegible] precaution may have to be suspended so that meat [illegible] readily accessible No definition of brisk trade was [illegible]. Some butchers, if shouting their wares in a crowded [illegible], would claim they were carrying on a brisk trade [illegible] though customers were few The supposition that [illegible] was a brisk trade every Saturday night had been [illegible] to cover Friday night, then Thursday night, and [illegible] every night in the week The regulations dealing [illegible] the transport and handling of meat were admirably [illegible] out by the wholesalers.

Discussion.

[illegible] **Charles Porter** (Medical Officer of Health, [illegible]one) held that meat was an article of food which [illegible] not be sold in the gutter even from behind a glass [illegible]. Meat could be sold without being displayed, in [illegible] States it was only in the poorer quarters of large [illegible] that meat could be seen on sale at all. When the [illegible] were drawn up they had caused the usual [illegible] produced by all new legislation, the public health [illegible] had hoped too much, the butchers had feared too [illegible] from them The benefits they would produce were [illegible]ginning.

[illegible] J. S. **Lloyd** (Chief Veterinary Inspector, Sheffield) [illegible] that no food should be displayed for sale in such [illegible] as to allow contamination. He had experienced [illegible] owing to the absence of a definition of a shop [illegible] in Sheffield was only carried out for horseflesh [illegible] abroad He had persuaded stallkeepers to put glass tops over their counters Flies could be got rid of in shops by installing fans

Mr J A. **Dixon** (Veterinary Inspector, Leeds) said that the right of pig-keepers and small-holders to slaughter elsewhere than in a slaughter-house resulted in much unsatisfactory meat being consumed and the wholesalers complained The notification of emergency slaughter was largely ignored He disapproved of the blowing of meat by any method Meat-marking would shield from prosecution butchers who had bought meat with deep-seated undetected disease No butcher repented of having fitted a fixed glass window It should be made clear that retailers' men were required to wear protective clothing when handling meat

Mr W G **Collinge** (National Federation of Meat Traders Association) expressed his personal view that all foodstuffs should be required to be protected from contamination. Many butchers believed that meat should be exposed to a draught and so preferred the open window The way in which meat was sold in many parts of London to-day was a disgrace

Councillor J **Edwards** (Hornsey) agreed In some shops on Saturday nights meat was hung six to nine feet outside the shop on the edge of the spring blinds

Mr T **Topping** (Chief Sanitary Inspector, Rochester) thought that the regulations made as big a step forward at one time as could be expected The staff usually provided did not enable the regulations to be enforced

Lieut.-Colonel T **Dunlop Young** (Chief Veterinary Inspector, Smithfield Market) said that compulsory meat-marking should be instituted to prevent the waste of time and money resulting from meat being inspected officially several times

Mr. **Brennan de Vine** in reply, said that the inspector who visited many butchers' shops in a day could give a sounder opinion on the way to prevent contamination by flies and dirt than the butcher who remained in one shop all day long The open shop had the most flies Sunday morning and late Saturday night trade should be wiped out, there was none in Birmingham

On the motion of Colonel **Young**, seconded by Dr G. **Clark Trotter** (Medical Officer of Health, Islington), it was resolved that application should be made to the Ministry of Health for a complete revision of the Meat Regulations, this revision being made after consultation with all the trades concerned

THE QUALIFICATIONS OF PUBLIC ANALYSTS

The Minister of Health has laid down that if a person appointed as public analyst does not already hold such an appointment he must provide documentary evidence of competence in analytical chemistry, therapeutics, and microscopy. The Minister will accept the Fellowship of the Institute of Chemistry with the certificate granted by that body in the chemistry (including microscopy) of food, drugs, and water The medical diploma of a registered practitioner is accepted as sufficient evidence of competence in therapeutics and microscopy, but he will be required to furnish evidence of competence in analytical chemistry These requirements recognise the limitations of the chemist with the usual training who does not necessarily know anything about therapeutics or the microscopy of food and drugs, and of the medical man whose chemistry is apt to be a thing of the past but who has had considerable training in therapeutics and microscopy.

DEAFNESS EXPLAINED [1]

Mr Balbi in a short pamphlet with this ambitious title makes a reasonable attempt to explain shortly to fellow laymen the principles of sound and of hearing, and the various types of artificial aid. Serious criticism must however, be directed to a paragraph to the effect that "where the deafness has been gradual, hearing appliances can be tried as a means of relief without consulting a doctor, after all they can do no harm even if they are used" In the next paragraph he advises the reader to ascertain positively that his deafness is not due to wax before purchasing an appliance Now he does not say how this can be done without the aid of a doctor, and it is a fact that wax deep in the canal is not easy to discover. The first statement passes over the very common form of deafness of gradual onset, due to obstruction of the Eustachian tube, in which it is most important that time should not be wasted on experiments with apparatus instead of seeking early treatment In spite of these and a few similar faults, the book may be read with profit by deaf people before seeking the aid of appliances pear-shaped, the stalk of the pear representing the ureter, which becomes anterior to the spine at the level of the fourth lumbar vertebra It is important to remember this relationship of the pelvis to the vertebræ when differentiating between shadows in the renal area In a lateral view the shadow of a renal calculus will lie on the shadow of the vertebræ, except in the case of a large stone or a collection of stones with associated enlargement of the kidney, when it may be anterior to the vertebræ

[1] Deafness Explained. By C M P Balbi A.C G I, A.M I E E. With a foreword by Lord Charnwood London: John Bale, Sons, and Danielsson 1927 Pp 45 1s. net

Identification of Stones

As a result of the greatly improved technique of radiography, gall-stones may now be demonstrated on the X ray plate and may have to be distinguished from other opacities in the renal area The questions, therefore, which have to be settled in the interpretation of a shadow in the renal area are (1) is the shadow intra- or extra-renal? and (2) what is its exact position? A pyelogram will assist us to answer both these questions In many cases there is no element of doubt as to the character and position of a shadow in the renal area, but sometimes, in spite of the data supplied by the clinical history, and in spite of cystoscopy and catheterisation of the ureters, the ordinary radiogram cannot be interpreted with confidence When a stone of any appreciable size is in the kidney, a variable degree of dilatation of the entire pelvis or individual calyx may be demonstrated in the pyelogram, the changes may be the result of mechanical obstruction or inflammatory reaction, or a combination of both It must be remembered, however, that a stone may produce little or no apparent deformity Moreover, a stone in the pelvis may block the entrance of the opaque solution, so that there will be a ureterogram but no pyelogram

Here may be mentioned a point of considerable importance in pyelography for cases of suspected renal calculi—namely, the staining of stones

Uric acid calculi produce a particularly feeble shadow in a radiogram, and, as I have already said, the pyelogram may not reveal the condition, but if the opaque solution is withdrawn and a further picture taken after the lapse of, say, half an hour, there will be no difficulty in at once recognising the presence of the calculus

In a lateral radiogram the shadow of a gall-stone lies well in front of the vertebræ and, more often than not, on a lower plane than a renal shadow In cases of doubt a pyelogram settles the point Not infrequently there is difficulty in distinguishing between calcareous mesenteric or lumbar glands and a stone in the pelvis or ureter The relation of the ureter to the opacities can be shown by the introduction of an opaque catheter into the ureter, and a pyelogram will demonstrate that the shadows are extra-renal If there is still an element of doubt, a lateral pyelogram will indicate that the opacities are outside the urinary tract

Hydronephrosis and Nephroptosis

The diagnosis of a large hydronephrosis is not usually difficult, but there is a period in its development when the kidney is not obviously enlarged and may not even be felt; it is in this early stage that it is so important to arrive at the diagnosis before the kidney becomes the seat of sepsis, and irreparable damage has been done

It is in this early stage, when there are symptoms suggesting distension of the renal pelvis, that pyelography is of such value. In early hydronephrosis there is broadening and flattening of the major calyces, and loss of the terminal irregularities of the minor calyces

Congenital hydronephrosis is by no means an uncommon condition, and one frequently giving rise to hæmaturia. It not infrequently happens that an early case of hydronephrosis, producing hæmaturia, can be diagnosed by no other methods of investigation Probably bleeding diagnosed as "Essential hæmaturia" is often due to hydronephrosis, and if pyelography is performed, this error in diagnosis would be discovered and the appropriate treatment adopted In these cases of so-called essential hæmaturia, the demonstration of a normal pelvis by pyelography is of very definite value, excluding, as it does, many of the causes of blood in the urine Pyelography is undoubtedly useful in determining the cause of hæmaturia in cases where the ætiological factor cannot be otherwise ascertained

Nephroptosis usually presents no particular difficulty in diagnosis, but it is important to know whether or not the ureter is associated with kinking A pyelogram will show this In those cases where a bilateral pyelogram demonstrates a bilateral nephroptosis, unassociated with kinking of the ureter and with no resulting hydronephrosis, I think that there is a very definite doubt as to the advisability of operative interference.

Neoplasms and Tuberculosis

Clinically, the differential diagnosis of a neoplasm, pyonephrosis, and hydronephrosis may be extremely difficult, especially when an impassable obstruction is found in the upper urinary tract, if such is the case, although none of the injected solution enters the pelvis, the outline of the ureter is still of value, for a dilated ureter from ureteritis suggests an enlargement of the kidney from infection.

With the outline of a small ureter below the tumour, a neoplasm may be inferred, the ureter being atrophied from disuse

In a large percentage of cases of new growth of the kidney, pyelography will show a recognisable change in the renal pelvis There are occasions, however, when this method will not be of use except in a negative sense I have in mind a sarcoma of the renal capsule which is not invading a calyx and is not palpable In such a case a radiogram taken after perirenal infiltration with oxygen may be of value, for an alteration, produced by the tumour, may then be seen in the contour of the kidney

In tuberculous disease of the kidney, cystoscopy and catheterisation of the ureters will often give the diagnosis or confirm suspicions, but here again it is sometimes necessary to rely on pyelography

To illustrate this point I will refer to three recent cases The first was that of a man, aged 32, who for several months had been troubled with pain in the back, this he attributed to a motor-cycle accident which he had nine months before I saw him. He also stated that on one occasion he noticed blood in his urine I submitted him to the usual routine investigation Cystoscopy was negative, I catheterised both ureters, and the urine from each kidney revealed nothing I then took a pyelogram, and the resulting picture left no doubt in my mind that there was a tuberculous infection of the left kidney A nephrectomy was performed, and the pathological report confirmed the clinical diagnosis

The other two cases were very similar from the history, except that in one the cystoscopic picture showed, according to my notes, "a granular type of cystitis, suggestive of, but not typical of, a tuberculous infection" In all three the urine was negative for tubercle bacilli, and in all three the diagnosis, as suggested by pyelography, was confirmed at operation

These cases proved to me the extreme value of pyelography as an aid in arriving at an early and accurate diagnosis Especially is this important in cases of tuberculous disease of the kidney, when we realise these patients not infrequently complain merely of frequency of micturition, the duration of which may only be a matter of weeks Much valuable time may be saved, and thereby the patient's chances of recovery enhanced, by a speedy decision as to the correct line of treatment to adopt

Technique of Pyelography.

I think it is certainly preferable that pyelography should be carried out without general anæsthesia whenever possible This enables the patient to indicate to the surgeon when the renal pelvis is full Distension of the pelvis causes pain, which will increase to a colic if distension is continued

Personally I like to screen the patient and watch the fluid filling up the pelvis, so that I do not have to rely entirely upon the patient for information as to when the pelvis is full, for one pelvis may not be as sensitive as another

The fluid in the renal pelvis should be withdrawn before introducing the solution, unless this is done, inconvenience may be caused by the dilution of the opaque solution. It is advisable to use an opaque catheter of moderate size so as not to fill the lumen of the ureter completely, this is an additional safeguard against over-distension of the pelvis. It is well to avoid injecting the fluid when the eye of the catheter is in a calyx, for if this occurs, the pelvis may be only partly filled when pain is complained of, owing to distension of the calyx In certain cases it is an advantage gradually to withdraw the catheter and inject the solution so that the course and contour of the ureter may be seen At the same time it should be borne in mind that the ureter, being freely movable, can easily be made to follow an unusual course by injecting fluid when the tip of the catheter is low down in the ureter

When the exposure has been made the solution should be removed from the pelvis From the patient's point of view this obviates any unnecessary discomfort

Conclusion

Undoubtedly the most valuable possession we have for investigating the ætiological factors of disease are experience and careful observation, and interpretation of the patient's signs and symptoms At the same time, when we have in our hands such an accurate, safe, and reliable method of investigation as pyelography, there should be no hesitation to employ it

It gives me the greatest pleasure to acknowledge my indebtedness to Mr A E Webb-Johnson for his constant encouragement and advice at all times, and to Dr F G Nicholas my thanks are due for his valued coöperation in the X ray department of the Middlesex Hospital

THE COMMONWEALTH FUND

Mrs Stephen V Harkness, who died in New York last year, endowed a committee with a large sum of money to be administered for the "welfare of mankind," under no restrictions whatever The story of what has been made of this remarkable opportunity is long, intricate, and uniformly fascinating, and is told in the annual reports of the Commonwealth Fund, of which the eighth has just been issued. The executors of the Fund selected half-a-dozen fields, decided exactly what they were going to do, and set about it with quiet persistence The key-note of their efforts is constructive education, and, realising that no organisation was of the smallest use unless it was an integral part of the community among which it worked, they have devoted themselves mainly to sowing in the best soil they could find their special knowledge of the sciences of mental and physical health, to inducing communities to make their own executive machinery, to instructing them in its maintenance and expansions, and to training a large body of disciples to carry on and extend their work

In 1922 they began a five-year programme of national instruction in the principles of child guidance and mental hygiene Starting in Fargo, North Dakota, they established demonstration centres in two large towns and two rural districts in various States with the object of "translating into effective local action the available knowledge of measures which spell freedom and inspiration for the normal, healthful growth of children of all ages, as an integral part of a well-developed general health programme" The communities have all, as a result of these demonstrations, greatly increased their public health activities, and their example will undoubtedly stimulate others The aim of the Fund is always to combine and unify existing protective and educational measures into a practical working programme. Next year this demonstration work will be superseded by the establishment of an Institute of Child Guidance for training psychiatrists, psychologists, and psychiatric social workers in practical child welfare work

The Division of Education and Legal Research allots 20 fellowships annually to British university graduates to enable them to study education at an American university, and acquire a first-hand knowledge of social conditions in the States This interchange of educational ideas is a decided step towards mutual understanding between the two countries The same division also publishes many sociological works, and studies administrative law and its practice — a very wide and difficult field in a country with numerous self-governing States The Rural Hospitals Division assists country districts to build and maintain hospitals, and has laid down a programme for two every year

The Fund is doing useful work in Austria, and it is a testimony to the soundness of its policy that the American personnel numbers only three, all the rest of the organisation being native The various activities include child health centres, tuberculosis stations, school hygiene institutes, and health education generally In an enterprise of this kind everything depends on the personality of the directors, and the surest guarantee for the permanence of the work is the continual and thorough training of potential successors to the present Committee that takes place as part of the execution of the Fund's objects

THE AJAX PORTABLE ARC LAMP

The lamp which has been submitted to us is designed as a portable source of ultra-violet radiation to be taken to the patient's house and used on the ordinary house mains Such a lamp must obviously be of reasonable size and weight, simple to use, and capable of running on any voltages direct or alternating The instrument submitted consists of a strong metallic case, about the size and shape of a large attaché case, heavily nickel-plated, which contains a small automatic arc and the necessary resistances The arc itself is permanently mounted at one end of the case and is not intended to be removed when in use This makes for safety in handling and for simplicity, as the minimum of fitting-up is required The end facing the arc forms a sliding panel which can be completely withdrawn when a wide-angled beam, suitable for the irradiation of a large area, is required For localised treatment, the sliding front carries a diaphragm and a water-cooled chamber fitted with rock crystal windows The water cooling is effected by a glass reservoir on the top of the instrument convection currents causing the water to circulate between the reservoir and the water chamber This simple arrangement was found to be quite effective for the short period required—in ten minutes the temperature of the water had risen only 7° C, whilst the quartz lens, though warm, was not uncomfortably hot

The arc is formed between cored carbons, either tungsten-cored or so-called polymetallic, the latter being cored with a mixture of metals designed to give intense radiation in the region of most therapeutic valu [illegible]

instrument three knife switches are fitted One is th
switch for the arc, the second has two positions corresp
to main voltages of 220 and 110 respectively The i
ment is sufficiently flexible to allow of its use on
voltages varying within 10 per cent of these values
third switch allows the use of the magnetic blower w
fitted to the arc, this is an electro-magnet which for
arc forward in the form of a flame when in use and t
increases the output of radiation The main switch h
contacts, one controlling the arc in the case and the
switching the current to a second arc which is moun
a hood-shaped reflector carried at the end of an adj
arm attached to the top of the case This arc can b
with a rock crystal lens applicator as described abov
in this case, no cooling device is fitted, the heat not b
intense as for the internal type

The instrument takes about eight ampères of curre
was found on test to give a very steady output T
tended to get hot during a prolonged run but, owing
efficient ventilation of arc and resistances, no dama
detected. The radiation from the bare arc and als
it had passed through the applicators was examined
Hilger quartz spectroscope The spectra extended a
2100 Angstrom units and the quartz lenses were fo
be transparent over the whole range The polym
carbons gave a spectrum of closely packed line
practically the whole range A few minor points of de
e g, the disposition of the switches on the case, call fo
modification, but they are by no means important a
already receiving the attention of the manufacturers

In general, the Ajax lamp seems to be very well de
for its purpose—namely, to provide a portable sou
ultra-violet rays which can be used over a wide ra
varying conditions and for a number of different pu
It may be obtained from the manufacturers, Ajax

THE SCANDAL OF HOMEWORK

Our attention has been called to an article in t
issue of the *Teachers' World* which describes, with d
evidence in support of the view, the possible defeat
true purpose of education by the intolerable burden
the homework set for children is becoming The educ
journal is definite in its statement that "the r
system of excessive homework is fast becoming a
to the physical and mental welfare of the adole
We do not know of any medical evidence which wou
out to the letter this formidable indictment, but,
Teachers' World will refer to the subject in its fol
issues, there may be more to be said on this groun
the futility as well as exhausting nature of the k
homework which apparently is being set, there can
doubt, when we read the examples set out As mu
expected, the teacher of mathematics appears to
worst offender in setting unsuitable and excessive hom
Here it seems that the sort of problems that child
their early teens are asked to deal with requir
monotonous calculation which, instead of leading to
mathematical outlook, and so providing a basis upon
advanced mathematical work can be built, can only a
in disgusting the pupil with the whole study The l
of mathematics can be made highly interesting
a fascinating intellectual exercise while it deals wi
coldest facts of life, it is deplorable that the reverse
so often occur through the unintelligent approach of te
to their subject

PARENTERAL MERCURIC POISONING

The administration by the mouth of sodium hypos
(that is to say, $Na_2S_2O_4$ in the strict chemical sense, n
thiosulphate commonly known as "hypo") has been
by E Hesse[1] to be a fairly trustworthy antidote to co
sublimate similarly administered Of 17 dogs re
lethal doses of sublimate, 13 recovered when this sub
was administered The action is probably partly a re
of the soluble salt to the metal and partly a formatio
insoluble sulphide As an industrial poison mer
usually taken through the lungs, and could best be t
by intravenous injections Sodium hyposulphite
has a reducing action on oxyhæmoglobin, and Hess
recently experimented with various compounds cont
sulphur, and as a result of his experiments recommen
use of the thioacetates Of these the strontium salt a
to be the most satisfactory for administration Inje
of at least 1 g a day should be continued for one o
weeks This use of sulphur compounds, which app
act by forming the extremely insoluble mercuric sul
is interesting, and is worthy of consideration by thos
